Tooth decay develops at varying rates. It may be found during a routine six-month dental checkup before the patient is even aware of a problem. In other cases, the patient may experience common early symptoms, such as sensitivity to hot and cold liquids or localized discomfort after eating very sweet foods. The dentist or dental hygienist may suspect tooth decay if a dark spot or a pit is seen during a visual examination. Front teeth may be inspected for decay by shining a light from behind the tooth. This method is called transillumination. Areas of decay, especially between the teeth, will appear as noticeable shadows when teeth are transilluminated. X rays may be taken to confirm the presence and extent of the decay. The dentist then makes the final clinical diagnosis by probing the enamel with a sharp instrument.

Tooth decay in pits and fissures may be differentiated from dark shadows in the crevices of the chewing surfaces by a dye that selectively stains parts of the tooth that have lost mineral content. A dentist can also use this dye to tell whether all tooth decay has been removed from a cavity before placing a filling.

Diagnosis in children

Damage caused by baby bottle tooth decay is often not diagnosed until the child has a severe problem, because parents seldom bring infants and toddlers in for dental check-ups. Dentists want to initially examine primary teeth between 12 and 24 months. Children still drinking from a bottle anytime after their first birthday are likely to have tooth decay.

Treatment

To treat most cases of tooth decay in adults, the dentist removes all decayed tooth structure, shapes the sides of the cavity, and fills the cavity with an appropriate material, such as silver amalgam or composite resin. The filling is put in to restore and protect the tooth. If decay has attacked the pulp, the dentist or a specialist called an endodontist may perform **root canal treatment** and cover the tooth with a crown.

In cases of baby bottle tooth decay, the dentist must assess the extent of the damage before deciding on the treatment method. If the problem is caught early, the teeth involved can be treated with fluoride, followed by changes in the infant's feeding habits and better **oral hygiene**. Primary teeth with obvious decay in the enamel that has not yet progressed to the pulp need to be protected with stainless steel crowns. Fillings are not usually an option in small children because of the small size of their teeth and the concern of recurrent decay. When the decay has advanced to the pulp, pulling the tooth is often the treatment of choice. Unfortunately, loss of primary teeth at this age may hinder the young child's ability to eat and speak. It may also have bad effects on the alignment and spacing of the permanent teeth when they come in.

Prognosis

With timely diagnosis and treatment, the progression of tooth decay can be stopped without extended **pain**. If the pulp of the tooth is infected, the infection may be treated with **antibiotics** prior to root canal treatment or extraction. The longer decay goes untreated, however, the more destructive it becomes and the longer and more intensive the necessary treatment will be. In addition, a patient with two or more areas of tooth decay is at increased risk of developing additional cavities in the future.

Prevention

It is easier and less expensive to prevent tooth decay than to treat it. The four major prevention strategies include: proper oral hygiene; fluoride; sealants; and attention to diet.

Oral hygiene

GENERAL CARE OF THE MOUTH. The best way to prevent tooth decay is to brush the teeth at least twice a day, preferably after every meal and snack, and floss daily. Cavities develop most easily in spaces that are hard to clean. These areas include surface grooves, spaces between teeth, and the area below the gum line. Effective brushing cleans each outer tooth surface, inner tooth surface, and the horizontal chewing surfaces of the back teeth, as well as the tongue. Flossing once a day also helps prevent gum disease by removing food particles and plaque at and below the gum line, as well as between teeth. Patients should visit their dentist every six months for oral examination and professional cleaning.

MOUTH CARE IN OLDER ADULTS. Older adults who have lost teeth or had them removed still need to maintain a clean mouth. Bridges and dentures must be kept clean to prevent gum disease. Dentures should be relined and adjusted by a dentist whenever necessary to maintain

KEY TERMS

Amalgam—A mixture (alloy) of silver and several other metals, used by dentists to make fillings for cavities.

Caries—The medical term for tooth decay.

Cavity—A hole or weak spot in the tooth surface caused by decay.

Dentin—The middle layer of a tooth, which makes up most of the tooth's mass.

Enamel—The hard, outermost surface of a tooth.

Fluoride—A chemical compound containing fluorine that is used to treat water or applied directly to teeth to prevent decay.

Mucin—A protein in saliva that combines with sugars in the mouth to form plaque.

Plaque—A thin, sticky, colorless film that forms on teeth. Plaque is composed of mucin, sugars from food, and bacteria that live in the plaque.

Pulp—The soft, innermost layer of a tooth containing blood vessels and nerves.

Sealant—A thin plastic substance that is painted over teeth as an anti-cavity measure to seal out food particles and acids produced by bacteria.

Transillumination—A technique of checking for tooth decay by shining a light behind the patient's teeth. Decayed areas show up as spots or shadows.

proper fit. These adjustments help to keep the gums from becoming red, swollen, and tender.

MOUTH CARE IN CHILDREN. Parents can easily prevent baby bottle tooth decay by not allowing a child to fall asleep with a bottle containing sweetened liquids. Bottles should be filled only with plain, unsweetened water. The child should be introduced to drinking from a cup around six months of age and weaned from bottles by twelve months. If an infant seems to need oral comfort between feedings, a pacifier specially designed for the mouth may be used. Pacifiers, however, should never be dipped in honey, corn syrup, or other sweet liquids. After the eruption of the first tooth, parents should begin routinely wiping the infant's teeth and gums with a moist piece of gauze or a soft cloth, especially right before bedtime. Parents may begin brushing a child's teeth with a small, soft toothbrush at about two years of age, when most of the primary teeth have come in. They should apply only a very small amount (the size of a pea) of toothpaste containing fluoride. Too much fluoride may cause spotting (fluorosis) of the tooth enamel. As the child grows, he or she will learn to handle the toothbrush, but parents should control the application of toothpaste and do the followup brushing until the child is about seven years old.

Fluoride application

Fluoride is a natural substance that slows the destruction of enamel and helps to repair minor tooth decay damage by remineralizing tooth structure. Toothpaste, mouthwash, fluoridated public drinking water, and vitamin supplements are all possible sources of fluoride. Children living in areas without fluoridated water should receive 0.5 mg/day of fluoride (0.25 mg/day if using a toothpaste containing fluoride) from three to five years of age, and 1 mg/day from six to12 years.

While fluoride is important for protecting children's developing teeth, it is also of benefit to older adults with receding gums. It helps to protect their newly exposed tooth surfaces from decay. Older adults can be treated by a dentist with a fluoride solution that is painted onto selected portions of the teeth or poured into a fitted tray and held against all the teeth.

Sealants

Because fluoride is most beneficial on the smooth surfaces of teeth, sealants were developed to protect the irregular surfaces of teeth. A sealant is a thin plastic coating that is painted over the grooves of chewing surfaces to prevent food and plaque from being trapped there. Sealant treatment is painless because no part of the tooth is removed, although the tooth surface is etched with acid so that the plastic will adhere to the rough surface. Sealants are usually clear or tooth-colored, making them less noticeable than silver fillings. They cost less than fillings and can last up to 10 years, although they should be checked for wear at every dental visit. Children should get sealants on their first permanent "6-year" molars, which come in between the ages of five and seven, and on the second permanent "12-year" molars, which come in between the ages of 11 and 14. Sealants should be applied to the teeth shortly after they erupt, before decay can set in. Although sealants have been used in the United States for about 25 years, one survey by the National Institute of Dental Research reported that fewer than 8% of American children have them.

Diet

The risk of tooth decay can be lowered by choosing foods wisely and eating less often. Foods high in sugar and starch, especially when eaten between meals, increase the risk of cavities. The bacteria in

the mouth use sugar and starch to produce the acid that destroys the enamel. The damage increases with more frequent eating and longer periods of eating. For better dental health, people should eat a variety of foods, limit the number of snacks, avoid sticky and overly sweetened foods, and brush often after eating.

Drinking water is also beneficial for rinsing food particles from the mouth. Children can be taught to "swish and swallow" if they are unable to brush after lunch at school. Similarly, saliva stimulated during eating makes it more difficult for food and bacteria to stick to tooth surfaces. Saliva also appears to have a buffering effect on the acid produced by the plaque bacteria and to act as a remineralizing agent. Older patients should be made aware that some prescription medications may decrease salivary flow. Less saliva tends to increase the activity of plaque bacteria and encourage further tooth decay. Chewing sugarless gum increases salivation and thus helps to lower the risk of tooth decay.

Bethany Thivierge

Tooth extraction

Definition

Tooth extraction is the removal of a tooth from its socket in the bone.

Purpose

Extraction is performed for positional, structural, or economic reasons. Teeth are often removed because they are impacted. Teeth become impacted when they are prevented from growing into their normal position in the mouth by gum tissue, bone, or other teeth. Impaction is a common reason for the extraction of wisdom teeth. Extraction is the only known method that will prevent further problems. Teeth may also be extracted to make more room in the mouth prior to straightening the remaining teeth (orthodontic treatment), or because they are so badly positioned that straightening is impossible. Extraction may be used to remove teeth that are so badly decayed or broken that they cannot be restored. In addition, patients sometimes choose extraction as a less expensive alternative to filling or placing a crown on a severely decayed tooth.

A close-up view inside a person's mouth following the extraction of the lower right molar. *(Custom Medical Stock Photo, Inc. Reproduced by permission.)*

Precautions

In some situations, tooth extractions may need to be postponed temporarily. These situations include:

- Infection that has progressed from the tooth into the bone. Infections may make anesthesia difficult. They can be treated with antibiotics before the tooth is extracted.
- The patient's use of drugs that thin the blood (anticoagulants). These medications include warfarin (Coumadin) and aspirin. The patient should stop using these medications for three days prior to extraction.
- Patients who have had any of the following procedures in the previous six months: heart valve replacement, open heart surgery, prosthetic joint replacement, or placement of a medical shunt. These patients may be given antibiotics to reduce the risk of bacterial infection.

Description

Tooth extraction can be performed with **local anesthesia** if the tooth is exposed and appears to be easily removable in one piece. An instrument called an elevator is used to loosen (luxate) the tooth, widen the space in the

KEY TERMS

Dry socket—A painful condition following tooth extraction in which a blood clot does not properly fill the empty socket. Dry socket leaves the underlying bone exposed to air and food.

Extraction site—The empty tooth socket following removal of the tooth.

Impacted tooth—A tooth that is growing against another tooth, bone, or soft tissue.

Luxate—To loosen or dislocate the tooth from the socket.

Nitrous oxide—A colorless, sweet-smelling gas used by dentists for mild anesthesia. It is sometimes called laughing gas because it makes some patients feel giddy or silly.

Oral surgeon—A dentist who specializes in surgical procedures of the mouth, including extractions.

Orthodontic treatment—The process of straightening teeth to correct their appearance and function.

bone, and break the tiny elastic fibers that attach the tooth to the bone. Once the tooth is dislocated from the bone, it can be lifted and removed with forceps.

If the extraction is likely to be difficult, the dentist may refer the patient to an oral surgeon. Oral surgeons are specialists who are trained to give nitrous oxide, an intravenous sedative, or a general anesthetic to relieve **pain**. Extracting an **impacted tooth** or a tooth with curved roots typically requires cutting through gum tissue to expose the tooth. It may also require removing portions of bone to free the tooth. Some teeth must be cut and removed in sections. The extraction site may or may not require one or more stitches to close the cut (incision).

Preparation

Before an extraction, the dentist will take the patient's medical history, noting **allergies** and prescription medications. A dental history is also taken, with particular attention to previous extractions and reactions to anesthetics. The dentist may then prescribe **antibiotics** or recommend stopping certain medications prior to the extraction. The tooth is x-rayed to determine its full shape and position, especially if it is impacted.

If the patient is going to have deep anesthesia, he or she should wear loose clothing with sleeves that are easily rolled up to allow for an intravenous line. The patient should not eat or drink anything for at least six hours before the procedure. Arrangements should be made for a friend or relative to drive the patient home after the surgery.

Aftercare

An important aspect of aftercare is encouraging a clot to form at the extraction site. The patient should put pressure on the area by biting gently on a roll or wad of gauze for several hours after surgery. Once the clot is formed, it should not be disturbed. The patient should not rinse, spit, drink with a straw, or smoke for at least 24 hours after the extraction and preferably longer. Vigorous **exercise** should not be done for the first three to five days.

For the first two days after the procedure, the patient should drink liquids without using a straw, and eat soft foods. Any chewing must be done on the side away from the extraction site. Hard or sticky foods should be avoided. The mouth may be gently cleaned with a toothbrush, but the extraction area should not be scrubbed.

Wrapped ice packs can be applied to reduce facial swelling. Swelling is a normal part of the healing process. It is most noticeable in the first 48–72 hours. As the swelling subsides, the patient may experience muscle stiffness. Moist heat and gentle exercise will restore jaw movement. The dentist may prescribe medications to relieve the postoperative pain.

Risks

Potential complications of tooth extraction include postoperative infection, temporary **numbness** from nerve irritation, jaw fracture, and jaw joint pain. An additional complication is called dry socket. When a blood clot does not properly form in the empty tooth socket, the bone beneath the socket is painfully exposed to air and food, and the extraction site heals more slowly.

Normal results

After an extraction, the wound usually closes in about two weeks. It takes three to six months for the bone and soft tissue to be restructured. Complications such as infection or dry socket may prolong the healing time.

Tooth grinding *see* **Bruxism**

Tooth replacements and restorations

Definition

A tooth restoration is any artificial substance or structure that replaces missing teeth or part of a tooth in order to protect the mouth's ability to eat, chew, and speak. Restorations include fillings, inlays, crowns, bridges, partial and complete dentures, and **dental implants**.

Purpose

Restorations have somewhat different purposes depending on their extensiveness. Fillings, inlays, and crowns are intended to repair damage to individual teeth. They replace tooth structure lost by decay or injury, protect the part of the tooth that remains, and restore the tooth's shape and function. Bridges, dentures, and implants are intended to protect the shape and function of the mouth as a whole.

Precautions

Some patients are allergic to the medications used for **local anesthesia** in dental restorations. In addition, many people in the general population are afraid of dental work. Most dentists in present-day practice can help patients with this specific fear.

Description

Fillings

Fillings are restorations that are done to repair damage caused by **tooth decay** (dental caries). Tooth decay occurs when microorganisms in the mouth convert sugar from food to acid, which attacks the tooth. The acid forms cavities that start in the hard outer surface of the tooth (the enamel) and may extend inward to the pulp, which contains the tooth's nerves and blood vessels. Left untreated, tooth decay may lead to inflammation and infection that may cause **toothache** and perhaps more serious complications.

To stop the decay process, the dentist removes the decayed portion of the tooth using a high-speed drill or an air abrasion system, shapes the cavity walls, and replaces the tooth structure with a filling of silver amalgam, composite resin, or gold. The filling is placed in the cavity as a liquid or soft solid. It sets within a few minutes and continues to harden over the next several hours. Silver amalgam is commonly used to fill cavities on the biting surfaces of the back teeth, because it is strong enough to withstand the tremendous pressures exerted by grinding and chewing. Composite resin is typically used to fill cavities in front teeth and any other teeth that are visible when the patient smiles, because its color can be matched to the tooth surface. Gold as a filling material is far less common, but is being increasingly used. Although it is more expensive and less easily applied, it does not trigger the sensitivity reactions that some patients have to silver amalgam.

Inlays

An inlay resembles a filling in that it fills the space remaining after the decayed portion of a tooth has been removed. The difference is that an inlay is shaped outside the patient's mouth and then cemented into place. After the decay is removed and the cavity walls are shaped, the dentist makes a wax pattern of the space. A mold is cast from the wax pattern. An inlay, usually of gold, is made from this mold and sealed into the tooth with dental cement.

Crowns

The crown of a tooth is the portion that is covered by enamel. A restorative crown replaces this outer part to protect the tooth. This protection becomes necessary when a tooth cracks or has its entire structure weakened by decay. As with a filling or inlay, the dentist first removes the decayed portion of the tooth. The tooth is then prepared for a crown. It may be tapered on the outside edges to a peg, reinforced with a cast metal core, or rebuilt with both a cast metal core and a post. A wax impression of the prepared tooth and the teeth next to it is made. The new crown is made to fit this mold. The crown may be made of gold or stainless steel alone, metal with a veneer of tooth-colored porcelain or resin, or of porcelain or resin alone. The finished crown is then placed over the prepared tooth, adjusted, and cemented into place.

Bridges

Bridges are a type of restoration that is done when one or more permanent teeth are lost or pulled. The resulting gap must be filled in to prevent the remaining teeth from shifting. If the other teeth shift, they will affect the patient's bite (occlusion), which sometimes produces **pain** in the jaw joint. As the teeth move and become crooked, they also become more difficult to keep clean. The risk of tooth decay and gum disease increases, increasing the likelihood that additional teeth will be lost. A bridge is inserted to prevent this risk. Bridges are nonremovable appliances of one or more artificial teeth (pontics) anchored by crowns on the adjacent teeth (abutment teeth). The abutment teeth carry the pressure when the patient chews food.

Partial dentures

A partial denture is similar to a bridge in that it fills a gap left by missing teeth with artificial teeth on a metal frame. A partial denture is removable, however. It attaches to a crown on the abutment tooth with a metal clasp or precision attachment. A partial denture is primarily used at the end of a row of natural teeth, where there is only one abutment tooth. The pressure exerted by chewing is shared by this abutment and the soft tissues of the gum ridge beneath the appliance.

Complete dentures

Complete dentures may be worn when all of the top or bottom teeth have been lost. A complete denture consists of artificial teeth mounted in a plastic base molded to fit the remaining oral anatomy. It may or may not be held in place with a denture adhesive.

Implants

Dental implants are a means of securing crowns, bridges, and dentures in the mouth. A hard plastic or metal fixture is implanted through the soft tissue into the bone. Over time, the bone grows around this fixture, firmly anchoring it. The exposed end of this fixture is covered with a crown and may serve as a stable abutment for a bridge or denture.

Preparation

Before a restoration is placed in the mouth, the dentist removes all traces of decay and shapes the remaining tooth structure for the restoration. Fillings are the only restoration created within the tooth itself–the others are made up in a laboratory using a model of the tooth structure. Thus, a filling may be placed in a single dental visit, while the other restorations usually take several appointments. Temporary crowns and dentures are put in place after the tooth is shaped until the permanent restoration is delivered by the laboratory.

Aftercare

Fillings

Fillings need time to harden for several hours after being placed, so the patient should chew food on the opposite side of the mouth for the first day.

Dentures

A partial or complete denture may take several weeks of getting used to. Inserting and removing the denture will take practice. Speaking clearly may be difficult at first–the patient may find it helpful to read out loud for practice. Eating may also feel awkward.

KEY TERMS

Abutment tooth—A crowned tooth that stabilizes a bridge or partial denture.

Bridge—An appliance of one or more artificial teeth anchored by crowns on the adjacent teeth.

Complete denture—A full set of upper or lower teeth, mounted in a plastic base. Dentures are also called false teeth.

Crown—A protective shell that fits over the tooth.

Dental caries—A disease of the teeth in which microorganisms convert sugar in the mouth to acid that erodes the tooth.

Enamel—The hard outermost surface of a tooth.

Filling—Dental material that occupies the space remaining within a tooth after the decayed portion has been removed.

Implant—A fixture with one end implanted into the bone and the other end covered with a crown, often to serve as a stable abutment for a bridge or denture.

Inlay—A filling that is made outside of the tooth and then cemented into place.

Occlusion—The way upper and lower teeth fit together during biting and chewing.

Partial denture—A removable bridge that usually clasps onto only one abutment.

Pontic—An artificial tooth.

Pulp—The soft innermost layer of a tooth that contains its blood vessels and nerves.

The patient should begin by eating small pieces of soft foods. Very hard or sticky foods should be avoided.

Patients with dentures must work on good **oral hygiene**. Specialty brushes and floss threaders may be used to remove plaque and food from around crowns and bridges. Dentures should be removed and brushed daily with a specially designed brush and a denture cleaner or other mild soap.

The patient should see the dentist for an adjustment if there is any discomfort or irritation resulting from a restoration. Otherwise, the patient should see the dentist at least twice a year for an oral examination.

Risks

Restoration procedures typically require local anesthesia. Some people may have allergic reactions to the medication. A very small number of people are allergic to one or more of the metals used in a dental

restoration. In most cases, the dentist can use another material.

Normal results

A well-made restoration should feel comfortable and last a relatively long time with proper care. Artificial dental restorations only approximate the original tooth, however. A complete denture will never feel as comfortable or work as well as natural teeth. It is better, therefore, to prevent the need for restorative dental work than to replace teeth. Restorations are expensive, may require many appointments, and still need careful cleaning and attention.

Toothache

Definition

A toothache is any **pain** or soreness within or around a tooth, indicating inflammation and possible infection.

Demographics

Serious toothaches and oral health problems are much less common today than ever before in history. The widespread availability of preventive dentistry and toothbrushes, toothpaste, and other oral care items has greatly improved oral health. However, most people experience some form of tooth pain at least once in their lives. Toothaches may occur more frequently in populations without regular access to dental care, such as low-income individuals. Toothaches also are more common in the elderly and individuals with certain diseases and conditions that make **tooth decay** more likely.

Description

A toothache may be either a sharp pain or a dull ache. The tooth may be sensitive to pressure, heat, cold, or sweets. In cases of severe pain, identifying the problem tooth can be difficult. Any patient with a toothache should see a dentist at once for diagnosis and treatment. Most toothaches get worse if not treated.

Causes and symptoms

Toothaches may result from many causes:

- tooth decay (dental caries)
- inflammation of the tooth pulp (pulpitis)
- abscess
- gum disease, including periodontitis
- loose or broken filling
- cracked or impacted tooth
- exposed tooth root
- food wedged between teeth or trapped below the gum line
- tooth nerve irritated by clenching or grinding of teeth (bruxism)
- pressure from congested sinuses
- traumatic injury

Diagnosis

Diagnosis includes identifying the location of the toothache, as well as the cause. The dentist begins by asking the patient specific questions about the toothache, including the types of foods that make the pain worse, whether the tooth is sensitive to temperature or biting, and whether the pain is worse at night. The dentist then examines the patient's mouth for signs of swelling, redness, and obvious tooth damage. The presence of pus indicates an **abscess** or gum disease. The dentist may flush the sore area with warm water to dislodge any food particles and to test for sensitivity to heat. The dentist may then dry the area with gauze to determine sensitivity to touch and pressure. The dentist may probe tooth crevices and the edges of fillings with a sharp instrument, looking for areas of tooth decay. Finally, the dentist may take x rays, looking for evidence of decay between teeth, a cracked or **impacted tooth**, or a disorder of the underlying bone.

Treatment

Emergency self-care

Toothaches should be professionally treated by a dentist. Some methods of self-treatment, however, may help manage the pain until professional care is available. Common home treatments include:

- rinsing with warm salt water
- using dental floss to remove any food particles

KEY TERMS

Abscess—A hole in the tooth or gum tissue filled with pus as the result of infection.

Bruxism—Habitual clenching and grinding of the teeth because of stress. The behavior usually occurs during sleep.

Cavity—A hole or weak spot in the tooth surface caused by decay.

Dental caries—A disease of the teeth in which microorganisms convert sugar in the mouth to acid, which then erodes the tooth.

Enamel—The hard outermost surface of a tooth.

Endodontist—A dentist who specializes in diagnosing and treating diseases of the pulp and other inner parts of the tooth.

Impacted tooth—A tooth that is growing against another tooth, bone, or soft tissue.

Periodontitis—A gum disease that destroys the structures supporting the teeth, including bone.

Pulp—The soft innermost part of a tooth, containing blood vessels and nerves.

Pulpitis—Inflammation of the pulp of a tooth that involves the blood vessels and nerves.

- taking aspirin or acetaminophen (Tylenol) to relieve pain; the drug should be swallowed and never placed directly on the aching tooth or gum
- applying a cold compress against the outside of the cheek; heat should not be used as it can increase the likelihood that the infection will spread
- using clove oil (*Syzygium aromaticum*) to numb the gums; the oil may be rubbed directly on the sore area or used to soak a small piece of cotton and applied to the sore tooth

Traditional treatment

Treatment will depend on the underlying cause of the toothache. If the pain is due to tooth decay, the dentist will remove the decayed area and restore the tooth with a filling of silver amalgam or composite resin. Loose or broken fillings are removed, new decay cleaned out, and a new filling is placed. If the pulp of the tooth is damaged, root canal therapy may be required. During a root canal the dentist or a specialist called an endodontist removes the decayed pulp, fills the space left behind with a soothing paste, and covers the tooth with a crown to protect and seal it. If the damage cannot be treated by these methods, or if the tooth is impacted, the tooth must be extracted.

Alternative treatment

Toothaches caused by infection or tooth decay must be treated by a dentist. Several alternative therapies may be helpful for pain relief until dental treatment is available. Clove oil (*Syzygium aromaticum*) may be rubbed on sensitive gums to numb them or added to a small cotton pellet that is then placed into or over a hole in the tooth. The herb corydalis (*Corydalis yanhusuo*) may also help relieve toothache pain. Pain also may be reduced using **acupressure**, **acupuncture**, or **reiki**. Acupuncture should be done only by a licensed practitioner.

Prognosis

Prompt dental treatment provides a positive outcome for toothache. In the absence of active infection, fillings, root canal treatments, or extractions may be performed with minimal discomfort to the patient. When a toothache is left untreated, a severe infection may develop and spread to the sinuses or jawbone, and eventually cause blood poisoning.

Prevention

Maintaining proper **oral hygiene** is the key to preventing toothaches. The best way to prevent tooth decay is to brush at least twice a day, preferably after every meal and snack. Flossing once a day also helps prevent gum disease by removing food particles and bacteria at and below the gum line, as well as between teeth. Visiting the dentist at least every six months for oral examinations and professional cleaning can help prevent a variety of oral health problems that can lead to toothache.

Topical anesthesia

Definition

Topical anesthesia is a condition of temporary **numbness** caused by applying a substance directly to a surface of the body. Loss of feeling occurs in the specific areas touched by the anesthetic substance.

Purpose

Topical anesthesia typically either relieves existing **pain** from a body surface or prevents pain during medical examinations or procedures. Body surfaces include both skin and mucous membranes, which are the moist linings of areas such as the inside of the mouth or nose. Occasionally, use of a topical anesthetic may help clarify whether a patient's pain comes from a body surface, which the substance is able to touch, or from deeper structures beyond the reach of the substance. A mucous membrane, an area of skin, or areas just beneath the skin's surface temporarily loses feeling during topical anesthesia.

Precautions

Topical anesthetic medications must be selected carefully and used in proper amounts in order to prevent harmful reactions. For instance, some topical drugs should be used only on intact skin to avoid rapid absorption into the body. Therefore, it is important to choose the right type and dosage of anesthetic for each specific purpose.

Description

Most drugs in the early 2000s used to cause topical anesthesia have at least some chemical similarity to **cocaine**, which was recognized as a topical anesthetic in the early 1900s. These drugs work by blocking nerve impulses that carry pain messages to the brain. Commonly used, twenty-first-century drugs include benzocaine, lidocaine, prilocaine, and tetracaine, These drugs come in several application forms, such as cream, jelly, ointment, solution, and spray, are available in varying strengths, and may be used alone or in combinations.

One common use for topical anesthetics is to relieve pain from problems such as sores in the mouth, skin scrapes, and **hemorrhoids**. A person typically applies a cream or jelly to the affected area. Numbness begins within a few minutes, and the anesthetic effect may last an hour or more. Repeated applications are often necessary.

The other broad category of use for topical anesthetics is to prevent pain from medical examinations or procedures on areas such as the eye, nose, throat, urethra, rectum, or skin. For example, even a single drop of anesthetic may allow examination of a painfully irritated eye or removal of a speck of dirt from the eye surface. Careful inspection of a nostril or insertion of a urinary drainage tube into the urethra may be difficult or impossible without the use of topical anesthetic spray or jelly beforehand.

Many uses of topical anesthetics involve application to the skin. Physicians and patients have long hoped for a way to numb an area of skin without having to use a needle to inject anesthetic. Original topical anesthetics were not effective in this way. A newer drug preparation called eutectic mixture of local anesthetics (EMLA, lidocaine 2.5%, and prilocaine 2.5%) can be used as a cream on intact skin. When applied for about 60 minutes, EMLA numbs the skin and penetrates as far as 5 mm below the surface. EMLA may help patients by decreasing the pain of needle pricks or simple skin procedures, such as repair of small lacerations. The main drawback to EMLA is that it takes so long for the anesthetic effect to begin, thus reducing its usefulness in settings such as the emergency rooms. Other drug combinations such as tetracaine, epinephrine (adrenaline), and cocaine (TAC), or lidocaine, epinephrine, and tetracaine (LET) have their own advantages and disadvantages.

The application of ice to a body area is a primitive method of producing topical anesthesia. Chemicals such as ethyl chloride can be sprayed onto intact skin to produce a momentary freezing and numbing effect.

KEY TERMS

Anesthetic—Not having sensation; related to the loss of sensation; or, a substance that produces loss of sensation.

EMLA—Eutectic mixture of local anesthetics, a drug combination for use on intact skin.

LET—A topical anesthetic mixture containing lidocaine, epinephrine, and tetracaine.

Mucous membranes—Moist linings of body surfaces such as the inside of the mouth or nose.

Numbness—Loss of feeling or sensation.

TAC—A topical anesthetic mixture containing tetracaine, epinephrine (adrenaline), and cocaine.

Topical—For use directly on a body surface.

Covering the ointment with plastic wrap increases the absorption of the ointment through the skin. The use of plastic wrap, or other occlusive **dressings**, is the standard means of applying EMLA cream. Other techniques include using gentle heat or electric current to help the drugs penetrate intact skin.

Risks

Overall, topical anesthesia tends to be very safe. Minor problems might include discoloration of the skin at the application site or an uncomfortable feeling of numbness that lasts longer than expected. Repeated use of a topical anesthetic on a damaged eye surface may interfere with the normal healing process. Rarely, too much of the drug may be absorbed into the body in a short time and cause a reaction such as seizure or rapid heartbeat. **Death** related to topical anesthesia is extremely rare.

Normal results

Successful use of a topical anesthetic produces temporary loss of sensation in the area where it is applied.

TORCH test

Definition

The TORCH test, which is sometimes called the TORCH panel, belongs to a category of blood tests called infectious-disease antibody titer tests. This type of blood test measures the presence of antibodies (protein molecules produced by the human immune system in response to a specific disease agent) and their level of concentration in the blood. The name of the test comes from the initial letters of the five disease categories. The TORCH test measures the levels of an infant's antibodies against five groups of chronic infections: *t*oxoplasmosis, *o*ther infections, *r*ubella, *c*ytomegalovirus (CMV), and *h*erpes simplex virus (HSV). The "other infections" usually include **syphilis**, **hepatitis B**, coxsackie virus, **Epstein-Barr virus**, varicella-zoster virus, and human parvovirus.

Since the TORCH test is a screening or first-level test, the pediatrician may order tests of other body fluids or tissues to confirm the diagnosis of a specific infection. In the case of **toxoplasmosis**, **rubella**, and syphilis, cerebrospinal fluid may be obtained from the infant through a spinal tap in order to confirm the diagnosis. In the case of CMV, the diagnosis is confirmed by culturing the virus in a sample of the infant's urine. In HSV infections, tissue culture is the best method to confirm the diagnosis.

Purpose

The five categories of organisms whose antibodies are measured by the TORCH test are grouped together because they can cause a cluster of symptomatic **birth defects** in newborns. This group of defects is sometimes called the TORCH syndrome. A newborn baby with these symptoms will be given a TORCH test to see if any of the five types of infection are involved.

The symptoms of the TORCH syndrome include:

- Small size in proportion to length of the mother's pregnancy at time of delivery. Infants who are smaller than would be expected (below the tenth percentile) are referred to as small-for-gestational-age, or SGA.
- Enlarged liver and spleen
- Low level of platelets in the blood
- Skin rash. The type of skin rash associated with the TORCH syndrome is usually reddish-purple or brown and is caused by the leakage of blood from broken capillaries into the baby's skin.
- Involvement of the central nervous system. These defects can include encephalitis, calcium deposits in the brain tissue, and seizures.
- Jaundice. The yellowish discoloration of the skin and whites of the eyes due to liver disease.

In addition to these symptoms, each of the TORCH infections has its own characteristic symptom cluster in newborns:

Toxoplasmosis

Toxoplasmosis is caused by *Toxoplasma gondii*, a parasite that the mother can acquire from handling infected cats, drinking unpasteurized milk, or eating contaminated meat. The infection is carried to the infant through the mother's placenta, and can cause infections of the eyes or central nervous system. The organism can invade brain or muscle tissue and form tissue cysts. The later in **pregnancy** that the mother is infected, the higher the probability that the fetus will be infected. On the other hand, toxoplasmosis early in pregnancy is more likely to cause a **miscarriage** or serious birth defects. The incidence of toxoplasmosis in newborns is one in 1,000 live births.

Other (syphilis)

Syphilis is caused by a spirochete (spiral- or coil-shaped bacterium), *Treponema pallidum*. It is transmitted in the adult population by sexual intercourse. About 2-5% of children born to mothers diagnosed with syphilis will have the disease at birth. Syphilis was added to the TORCH panel because of a rapid increase in reported cases since 1990. It is also a potentially life-threatening infection for the fetus. Syphilis can cause early delivery, miscarriage, or **stillbirth**. The mortality rate in infants infected with syphilis is about 54%.

Rubella

Rubella is a virus that has a seasonal pattern, with epidemics most likely in the spring. Between 0.1-2% of newborns will be infected with rubella. The rate of fetal infection varies according to the timing of the mother's infection during pregnancy. Birth defects, however, are most likely (85%) in infants infected during the first eight weeks of pregnancy. Infants born with rubella may already show signs of heart disease, retarded growth, **hearing loss**, blood disorders, vision problems, or **pneumonia**. They may also develop problems later in childhood, including **autism**, hearing loss, brain syndromes, immune system disorders, or thyroid disease.

Cytomegalovirus (CMV)

Cytomegalovirus belongs to the herpesvirus group of infections. It can be transmitted through body secretions, as well as by sexual contact; some newborns acquire CMV through the mother's breast milk. In adults, it produces symptoms resembling those of mononucleosis. About 1–2.2% of newborns in the United States are infected with CMV. Of this group, 10% will have measurable symptoms. The mortality rate for these symptomatic newborns is 20–30%. Surviving infants with CMV may suffer from hearing problems (15%) or **mental retardation** (30%). Newborns that acquire CMV during the birth process or shortly after birth may develop pneumonia, hepatitis, or various blood disorders.

Herpes simplex virus (HSV)

Herpesvirus infections are among the most common viral infections in humans. They are spread by oral, as well as genital, contact. It is estimated that between 1 in 1,000 and 1 in 5,000 infants are born with HSV infections. About 80% of these infections are acquired during the birth process itself; the virus enters the infant through its eyes, skin, mouth, and upper respiratory tract. Of infants born with HSV infection, about 20% will have localized infections of the eyes, mouth, or skin. About 50% of infected infants will develop disease spread throughout the body (disseminated) within nine to 11 days after birth. Disseminated herpes infections attack the liver and adrenal glands, as well as other body organs. Without treatment, the mortality rate is 80%. Even with antiviral medication, the mortality rate is still 15–20%, with 40–55% of the survivors having long-term damage to the central nervous system. It is critical for the doctor to diagnose HSV infection in the newborn as soon as possible, for effective treatment.

Description

The TORCH panel requires a sample of the infant's blood. Samples from infants are usually obtained by the heelstick procedure when only a small quantity of blood is needed. The baby's foot is wrapped

KEY TERMS

Antibody—A protein molecule produced by the immune system that is specific to a disease agent, such as CMV and the other organisms sought by the TORCH test. The antibody combines with the organism and disables it.

Perinatal—Referring to the period of time surrounding an infant's birth, from the last two months of pregnancy to the first 28 days of life. The TORCH panel tests for perinatal infections.

Small-for-gestational-age (SGA)—A term used to describe newborns who are below the 10th percentile in height or weight for their estimated gestational age. The gestational age is based upon the date of the mother's last menstrual period. SGA is one of the symptoms of TORCH syndrome.

Titer—The concentration of a substance in a given sample of blood or other tissue fluid.

in a warm cloth for five minutes, to make the blood flow more easily. The foot is then wiped with an alcohol swab and a lancet is used to stick the baby's heel on one side. It is important to avoid the center of the heel, in order to prevent an inflammation of the bone.

Preparation

No special preparation, other than sterile technique, is required.

Risks

The only complications associated with the TORCH test are those resulting from the heelstick technique itself. These risks include scarring, infection of the bone, **cellulitis** (inflammation of cellular tissue), small lumpy **calcium** deposits, and inaccurate test results.

Normal results

The normal result would be normal levels of immunoglobulin M (IgM) antibody in the infant's blood. IgM is one of five types of protein molecules found in blood that function as antibodies. IgM is a specific class of antibodies that seeks out virus particles. In contrast to adults, IgM is the most common type of immunoglobulin in newborn children. It is, therefore, the most useful indicator of the presence of a TORCH infection.

Abnormal results

The general abnormal, or positive, finding would be high levels of IgM antibody. The test can be refined further for antibodies specific to given disease agents. The TORCH screen, however, can produce both false-positive and false-negative findings. Doctors can measure IgM levels in the infant's cerebrospinal fluid, as well as in the blood, if they want to confirm the TORCH results.

Torticollis

Definition

Torticollis (cervical dystonia or spasmodic torticollis) is a type of movement disorder in which the muscles controlling the neck cause sustained twisting or frequent jerking.

Description

In torticollis, certain muscles controlling the neck undergo repetitive or sustained contraction, causing the neck to jerk or twist to the side. Cervical dystonia causes forward twisting, and is called antecollis. Backward twisting is known as retrocollis. The abnormal posture caused by torticollis is often debilitating, and is usually painful.

Torticollis most commonly begins between age 30–60, with females affected twice as often as males. According to the National Spasmodic Torticollis Association, torticollis affects 83,000 people in the United States. Dystonia tends to become more severe during the first months or years after onset, and may spread to other regions, especially the jaw, arm, or leg. Torticollis should not be confused with such other causes of abnormal neck posture as orthopedic or congenital problems.

Causes and symptoms

The nerve signals responsible for torticollis are thought to originate in the basal ganglia, a group of brain structures involved in movement control. The exact defect is unknown. Some cases of dystonia are

due to the inheritance of a defective gene, whose function was unknown as of 2010. Other cases are correlated with neck or head trauma, such as from an automobile accident. Use of certain **antipsychotic drugs**, or neuroleptics, can induce dystonia.

There are three types of torticollis:

- tonic, in which the abnormal posture is sustained
- clonic, marked by jerky head movements.
- mixed, a combination of tonic and clonic movements

Symptoms usually begin gradually, and may be intermittent at first, worsening in times of **stress**. Symptoms usually progress over two to five years, and then remain steady. Symptoms may be relieved somewhat when lying down. Many people with torticollis can temporarily correct their head position by sensory tricks, as touching the chin or cheek on the side opposite the turning. The reason for the effectiveness of this "geste antagoniste," as it is called, is unknown.

Pain in the neck, back, or shoulder affects more than two-thirds of all people with torticollis. Pain may spread to the arm or hand.

Diagnosis

Diagnosis of torticollis is aided by an electrical study (**electromyography**) that can detect overactive muscles. Imaging studies, including x rays, may be done to rule out other causes of abnormal posture. A detailed medical history is needed to determine possible causes, including trauma.

Treatment

A variety of oral drugs are available to relax muscles, including baclofen. For a subgroup of patients, L-dopa provides effective relief. Denervation of the involved neck muscles may be performed with injection of alcohol or phenol on to the nerve.

Injection of botulinum toxin (BTX) is considered by many to be the treatment of choice. By preventing release of chemical messages from the nerve endings that stimulate the involved muscles, BTX partially paralyzes the muscles, therefore allowing more normal posture and range of motion. BTX treatment lasts several months, and may be repeated.

Physical therapy can help relieve secondary consequences of torticollis. Regular muscle stretching prevents contracture, or permanent muscle shortening. Pain and spasm may be temporarily lessened with application of heat or ice. Stress management techniques may help prevent worsening. An occupational therapist can suggest home or work modifications to reduce **fatigue** and improve function. Braces constructed to replace the patient's own sensory tricks may help reduce abnormal posture.

Alternative treatment

Biofeedback may be effective for some patients. Regular **massage therapy** can reduce additional pain in compensating areas of the body. Two energy-based therapies, **acupuncture** and **homeopathic medicine**, can work to rebalance the whole person, helping to correct the torticollis. Antispasmodic herbs may help to relax the muscles. In addition, herbs that can help balance the stimulus from the nervous system are often recommended.

Prognosis

Spontaneous remission is seen in up to 20% of patients, most often those patients with older onset and milder symptoms. Dystonia may spread to affect other regions of the body.

Prevention

There is no way known to prevent torticollis.

Total parenteral nutrition

Definition

Total parenteral **nutrition** (TPN) is a way of supplying all the nutritional needs of the body by bypassing the digestive system and by administering nutrient solution directly into a vein. Other terms used synonymously with TPN include parenteral nutrition and hyperalimentation.

Purpose

TPN is used when individuals cannot or should not get their nutrition through eating. TPN is used when the intestines are obstructed, when the small intestine is not absorbing nutrients properly, or when a gastrointestinal **fistula** (abnormal connection) is

present. It is also used when the bowels need to rest and should not have any food passing through them. Bowel rest may be necessary in **Crohn's disease**, **pancreatitis**, ulcerative **colitis**, and with prolonged bouts of **diarrhea** in young children. TPN is also used for individuals with severe **burns**, multiple **fractures**, and in malnourished individuals to prepare them for major surgery, **chemotherapy**, or radiation treatment. Individuals with **AIDS** or widespread infection (**sepsis**) and other medical conditions may also benefit from the administration of TPN.

KEY TERMS

Catheter—A hollow tube that is inserted into veins or other passages in the body to insert or remove fluid.

Electrolyte—An ion such as potassium, sodium, or chloride dissolved in fluid that helps to regulate metabolic activities of cells.

Fistula—An abnormal passage that connects one organ to another or that connects the organ to the outside of the body.

Description

TPN is normally given through a large central vein. A catheter is inserted into the vein in the chest area under **local anesthesia** and sterile conditions. Placement may be done in an operating room to decrease the chance of infection. Several different types of catheters are used based on the reason TPN is needed and the expected length of treatment. Catheters are made of silicone or similar materials. Once the catheter is in place, a **chest x ray** is done to make sure the placement is correct.

Normally TPN is administered in a hospital, but under certain conditions and with proper patient and caregiver education, it may also be used at home for long–term therapy. TPN solution is mixed daily under sterile conditions. Maintaining sterility is essential for preventing infection. For this reason, the outside tubing leading from the bag of solution to the catheter is changed daily, and special **dressings** covering the catheter are changed daily as well.

The contents of the TPN solution are determined based on the age, weight, height, and medical condition of the individual. All solutions contain sugar (dextrose) for energy and protein (amino acids). Fats (lipids) may also be added to the solution. Electrolytes such as potassium, **sodium**, **calcium**, magnesium, chloride, and phosphate are also included, as these are essential to the normal functioning of the body. Trace elements such as zinc, copper, manganese and chromium are also needed. **Vitamins** can be included in the TPN solution, and insulin, a hormone that helps the body use sugar, may need to be added. Adults need approximately two liters of TPN solution daily, although this amount varies with age, size, and health of the individual. Special solutions have been developed for individuals with reduced liver and kidney function. The solution is infused slowly at first to prevent fluid imbalances, then the rate is gradually increased. The infusion process takes several hours.

Successful TPN requires frequent, often daily, monitoring of the individual's weight, glucose (blood sugar) level, blood count, blood gases, fluid balance, urine output, waste products in the blood (plasma urea) and electrolytes. Liver and **kidney function tests** may also be performed. Contents of the solution are individualized based on the results of these tests.

Precautions

Individuals need to tell their doctor if they have any **allergies**, what medications they are taking, if they are diabetic, have had liver, kidney, heart, lung, or hormonal disorders, and if they are pregnant. All these factors can affect the type and amount of TPN required.

Preparation

Preparation to insert the catheter involves creating a sterile environment. Other special preparations are not normally necessary.

Aftercare

During the time the catheter is in place, patients and caregivers must be alert to any signs of infection such as redness, swelling, **fever**, drainage, or **pain**.

Risks

TPN requires close monitoring. Two types of complications can develop. Infection, air in the lung cavity (**pneumothorax**), and blood clot formation (thrombosis) all can develop as a result of inserting the catheter into a vein. Metabolic and fluid imbalances can occur if the contents of the nutritional fluid are not properly balanced and monitored. The most common metabolic imbalance is **hypoglycemia**, or low blood sugar, caused by abruptly discontinuing a solution high in sugar.

Most of the time, TPN is administered through an infusion pump so that delivery of the fluids can be precisely monitored and calculated.

Results

Ideally TPN will provide all nutrients in the correct quantity to allow the body to function normally.

Tourette syndrome

Definition

Tourette syndrome (TS) is an inherited disorder of the nervous system that typically appears in childhood. The main features of TS are repeated movements and vocalizations called tics. TS can also be associated with behavioral and developmental problems.

Demographics

Tourette syndrome is a relatively common disorder found in all populations and all ethnic groups. TS is three to four times more common in males than females. The exact incidence of Tourette syndrome is unknown but it is estimated to affect 1 to 10 in 1,000 children. According to the National Institute for Neurological Disorders and **Stroke** (NINDS), an estimated 200,000 Americans have the most severe form of TS, and as many as one in 100 have milder symptoms such as chronic motor or vocal tics. Early TS symptoms are almost always noticed first in childhood, with the average onset between the ages of 7 and 10 years.

Description

Tourette syndrome is a variable disorder with onset in childhood. Though symptoms can appear anywhere between the ages of 2 and 18, typical onset is around age 6 or 7. Tics, which may be motor or vocal, tend to wax and wane (increase and decrease) in severity over time. The first references in the literature to what might today be classified as TS largely describe individuals who were wrongly believed to be possessed by the devil. In 1885 Gilles de la Tourette, a French neurologist, provided the first formal description of this syndrome, which he described as an inherited neurological condition characterized by motor and vocal tics.

Although vocal and motor tics are the hallmark of Tourette syndrome, other symptoms such as the expression of socially inappropriate comments or behaviors, obsessive compulsive disorder, attention deficit disorder, self injuring behavior, depression, and **anxiety** also appear to be associated with Tourette syndrome. Symptoms usually intensify during teenage years and diminish in late adolescence or early adulthood. Patients may also develop co–occurring behavioral disorders, namely obsessive–compulsive disorder (OCD), **attention deficit hyperactivity disorder (ADHD)** or attention deficit disorder (ADD), poor impulse control, and/or **sleep disorders**. Though some children have learning disabilities, intelligence is not impaired. TS is not degenerative and life span is normal.

Risk factors

As of 2009, TS risk factors are unknown, and researchers are studying risk factors before and after birth that may contribute to this complex disorder. Some of the suggested factors include severe psychological trauma, recurrent daily stresses, extreme emotional excitement, PANDAS (pediatric autoimmune neuropsychiatric disorder with streptococcal infection), and drug **abuse**.

Causes and symptoms

A variety of genetic and environmental factors likely play a role in causing TS. Studies suggest that the tics in Tourette syndrome are caused by an increased amount of a neurotransmitter called dopamine. A neurotransmitter is a chemical found in the brain that helps to transmit information from one brain cell to another. Other studies suggest that the defect in Tourette syndrome involves another neurotransmitter called serotonin or involves other chemicals required for normal functioning of the brain.

Genetic factors are believed to play a major role in the development of TS. Several chromosomal regions have been identified as possible locations of genes that confer susceptibility to TS. Some family studies have indicated that TS may be inherited in an autosomal dominant manner, but other studies have shown that this is not the case. Mutations involving the SLITRK1

gene have been identified in a small number of TS patients. This gene provides instructions for making a brain protein called SLITRK1. This protein probably plays a role in the development of nerve cells, including the growth of axons and dendrites that allow each nerve cell to communicate with nearby cells. It is unclear how mutations in the SLITRK1 gene can lead to this disorder. The inheritance pattern of Tourette syndrome remains unknown. Although the features of TS can cluster in families, many genetic and environmental factors are likely to be involved. Some researchers believe that Tourette syndrome has different causes in different individuals or is caused by changes in more than one gene. Further research is needed to establish the cause of Tourette syndrome.

Motor and vocal tics

The principal symptoms of Tourette syndrome include simple and complex motor and vocal tics. Simple motor tics are characterized by brief muscle contractions of one or more limited muscle groups. An eye twitch is an example of a simple motor tic. Complex motor tics tend to appear more complicated and purposeful than simple tics and involve coordinated contractions of several muscle groups. Some examples of complex motor tics include the act of hitting oneself and jumping. Copropraxia, the involuntary display of unacceptable/obscene gestures, and echopraxia, the imitation of the movement of another individual, are other examples of complex motor tics.

Vocal tics are actually manifestations of motor tics that involve the muscles required for vocalization. Simple vocal tics include **stuttering**, stammering, abnormal emphasis of part of a word or phrase, and inarticulate noises such as throat clearing, grunts, and high–pitched sounds. Complex vocal tics typically involve the involuntary expression of words. Perhaps the most striking example of this is coprolalia, the involuntary expression of obscene words or phrases, which occurs in fewer than one–third of people with Tourette syndrome. The involuntary echoing of the last word, phrase, sentence or sound vocalized by oneself (phalilalia) or of another person or sound in the environment (echolalia) are also classified as complex tics.

The type, frequency, and severity of tics exhibited varies tremendously between individuals with Tourette syndrome. Tourette syndrome has a variable age of onset and tics can start anytime between infancy and age 18. Initial symptoms usually occur before the early teens and the mean age of onset for both males and females is approximately seven years of age. Most individuals with symptoms initially experience simple muscle tics involving the eyes and the head. These symptoms can progress to tics involving the upper torso, neck, arms, hands, and occasionally the legs and feet. Complex motor tics are usually the latest onset muscle tics. Vocal tics usually have a later onset then motor tics. In some rare cases, people with Tourette syndrome suddenly present with multiple, severe, or bizarre symptoms.

Not only is there extreme variability in clinical symptoms between individuals with Tourette syndrome, but individuals commonly experience a variability in type, frequency, and severity of symptoms within the course of their lifetime. Adolescents with Tourette syndrome often experience unpredictable and variable symptoms, which may be related to fluctuating hormone levels and decreased compliance in taking medications. Adults often experience a decrease in symptoms or a complete end to symptoms.

A number of factors appear to affect the severity and frequency of tics. **Stress** appears to increase the frequency and severity of tics while concentration on another part of the body that is not taking part in a tic can result in the temporary alleviation of symptoms. Relaxation, following attempts to suppress the occurrence of tics, may result in an increased frequency of tics. An increased frequency and severity of tics can also result from exposure to drugs such as **steroids**, **cocaine**, amphetamines, and **caffeine**. Hormonal changes such as those that occur prior to the menstrual cycle can also increase the severity of symptoms.

Other associated symptoms

People with Tourette syndrome are more likely to exhibit non–obscene, socially inappropriate behaviors such as expressing insulting or socially unacceptable comments or socially unacceptable actions. It is not known whether these symptoms stem from a more general dysfunction of impulse control that might be part of Tourette syndrome.

Tourette syndrome appears to also be associated with attention deficit disorder (ADD). ADD is a disorder characterized by a short attention span and impulsivity and in some cases hyperactivity. Researchers have found that 21–90% of individuals with Tourette syndrome also exhibit symptoms of ADD, whereas 2–15% of the general population exhibit symptoms of ADD.

People with Tourette syndrome are also at higher risk for having symptoms of obsessive–compulsive disorder (OCD). OCD is a disorder characterized by persistent, intrusive, and senseless thoughts (obsessions) or compulsions to perform repetitive behaviors

KEY TERMS

Attention deficit disorder (ADD)—Disorder characterized by a short attention span, impulsivity, and in some cases hyperactivity.

Autosomal dominant—A pattern of genetic inheritance where only one abnormal gene is needed to display the trait or disease.

Axon—The long extension of a nerve fiber that generally conducts impulses away from the body of the nerve cell.

Coprolalia—The involuntary expression of obscene words or phrases.

Copropraxia—The involuntary display of unacceptable/obscene gestures.

Decreased penetrance—Individuals who inherit a changed disease gene but do not develop symptoms.

Dendrites—Fibers of a brain cell that receive signals from other brain cells.

Dysphoria—Feelings of anxiety, restlessness, and dissatisfaction.

Echolalia—Involuntary echoing of the last word, phrase, or sentence spoken by someone else or sound in the environment.

Echopraxia—The imitation of the movement of another individual.

Neurotransmitter—Chemical in the brain that transmits information from one nerve cell to another.

Obsessive compulsive disorder (OCD)—Disorder characterized by persistent, intrusive, and senseless thoughts (obsessions) or compulsions to perform repetitive behaviors that interfere with normal functioning.

Phalilalia—Involuntary echoing of the last word, phrase, sentence, or sound vocalized by oneself.

Tic—Brief and intermittent involuntary movement or sound.

that interfere with normal functioning. A person with OCD, for example, may be obsessed with germs and may counteract this obsession with continual hand washing. Symptoms of OCD are present in 1.9–3% of the general population, whereas 28–50% of people with Tourette syndrome have symptoms of OCD.

Self–injurious behavior (SIB) is also seen more frequently in those with Tourette syndrome. Approximately 34–53% of individuals with Tourette syndrome exhibit some form of self–injuring behavior. The SIB is often related to OCD but can also occur in those with Tourette syndrome who do not have OCD.

Symptoms of anxiety and depression are also found more commonly in people with Tourette syndrome. It is not clear, however, whether these symptoms are symptoms of Tourette syndrome or occur as a result of having to deal with the symptoms of moderate to severe Tourette syndrome.

People with Tourette syndrome may also be at increased risk for having learning disabilities and **personality disorders** and may be more predisposed to behaviors such as aggression, antisocial behaviors, severe temper outbursts, and inappropriate sexual behavior. Further controlled studies need to be performed, however, to ascertain whether these behaviors are symptoms of Tourette syndrome.

Diagnosis

Examination

The TS diagnosis is made through observation and interview of the patient and discussions with other family members. The diagnosis of Tourette syndrome is complicated by a variety of factors. The extreme range of symptoms of this disorder makes it difficult to differentiate Tourette syndrome from other disorders with similar symptoms. Diagnosis is further complicated by the fact that some tics appear to be within the range of normal behavior. For example, an individual who only exhibits tics such as throat clearing and sniffing may be misdiagnosed with a medical problem such as **allergies**. In addition, bizarre and complex tics such as coprolalia may be mistaken for psychotic or "bad" behavior. Diagnosis is also confounded by individuals who attempt to control tics in public and in front of health care professionals and deny the existence of symptoms. Although there is disagreement over what criteria should be used to diagnosis Tourette syndrome, one aid in the diagnosis is the *Diagnostical and Statistical Manual of Mental Disorders* (*DSM–IV*). The *DSM–IV* outlines suggested diagnostic criteria for a variety of conditions including Tourette syndrome such as:

- Presence of both motor and vocal tics at some time during the course of the illness.

- The occurrence of multiple tics nearly every day through a period of more than one year, without a remission of tics for a period of greater than three consecutive months.
- The symptoms cause distress or impairment in functioning.
- Age of onset of prior to 18 years of age.
- The symptoms are not due to medications or drugs and are not related to another medical condition.

Some physicians critique the *DSM–IV* criteria, citing that they do not include the full range of behaviors and symptoms seen in Tourette syndrome. Others criticize the criteria since they limit the diagnosis to those who experience a significant impairment, which may not be true for individuals with milder symptoms. For this reason many physicians use their clinical judgment as well as the *DSM–IV* criteria as a guide to diagnosing Tourette syndrome.

Tests

Patients may undergo blood tests, imaging studies such as **magnetic resonance imaging** (MRI), or an electroencephalogram (EEG) scan in order to rule out other possible explanations for the symptoms.

Treatment

There is no cure for Tourette syndrome, and treatment involves the control of symptoms through educational and psychological interventions and/or medications. The treatment and management of Tourette syndrome varies from patient to patient and is typically focused on the alleviation of the symptoms that are most bothersome to the patient or that cause the most interference with daily functioning.

Traditional

Psychological treatments such as counseling are not generally useful for the treatment of tics but can be beneficial in the treatment of associated symptoms such as obsessive–compulsive behavior and attention deficit disorder. Counseling may also help individuals to cope better with the symptoms of this disorder and to have more positive social interactions. Psychological interventions may also help people cope better with stressors that can normally be triggers for tics and negative behaviors. Relaxation therapies may, however, increase the occurrence of tics. Treatment is crucial in helping the affected child avoid depression, social isolation, and strained family relationships. The education of family members, teachers, and peers about Tourette syndrome can be helpful and may help to foster acceptance and prevent social isolation.

Drugs

Many people with mild symptoms of Tourette syndrome never require medications. Those with severe symptoms may require medications for all or part of their lifetime. No single or combination (more than one) drug therapy offers complete cessation of symptoms without adverse effects. The most effective treatment of tics associated with Tourette syndrome involves the use of drugs such as Haloperidol, Pimozide, Sulpiride, and Tiapride, which decrease the amount of dopamine in the body. Unfortunately, the incidence of side effects, even at low dosages, is quite high. The short–term side effects can include **sedation**, dysphoria, weight gain, movement abnormalities, depression, and poor school performance. Long–term side effects can include **phobias**, memory difficulties, and personality changes. These drugs are therefore better candidates for short–term rather than long–term therapy.

Tourette syndrome can also be treated with other drugs such as clonidine, clonazepam, and risperidone, but the efficacy of these treatments is unknown. In many cases, treatment of associated conditions such as ADD and OCD is often more of a concern than the tics themselves. Clonidine used in conjunction with stimulants such as Ritalin may be useful for treating people with Tourette syndrome who also have symptoms of ADD. Stimulants should be used with caution in individuals with Tourette syndrome since they can sometimes increase the frequency and severity of tics. OCD symptoms in those with Tourette syndrome are often treated with drugs such as Prozac, Luvox, Paxil, and Zoloft.

In many cases the treatment of Tourette syndrome with medications can be discontinued after adolescence. Trials should be performed through the gradual tapering off of medications and should always be done under a doctor's supervision.

Alternative

Clinical trials for the treatment of Tourette syndrome are currently sponsored by the National Institutes of Health (NIH) and other agencies. In 2009, NIH reported 22 ongoing or recently completed studies. Some examples include the following:

- A study to investigate how the sensitivity to touch and smell in patients with Tourette syndrome may differ from that of people without TS. (NCT00368433)
- The evaluation of whether deep brain stimulation is effective at reducing tic frequency and severity in adults with Tourette syndrome. (NCT00311909)

- A study using magnetic resonance imaging (MRI) and magnetic resonance spectroscopy (MRS) of the brain to try to gain a better understanding of the disease process in Tourette's syndrome. (NCT00030953)

Clinical trial information is constantly updated by NIH and the most recent information on Tourette syndrome trials can be found at: http://clinicaltrials.gov/search/open/condition=%22Tourette+Syndrome%22

Prognosis

The prognosis for Tourette syndrome in individuals without associated psychological conditions is often quite good, and only approximately 10% of Tourette syndrome individuals experience severe tic symptoms. Approximately 30% of people with Tourette syndrome will experience a decrease in the frequency and severity of tics and another 30–40% will experience a complete end of symptoms by late adolescence. The other 30–40% will continue to exhibit moderate to severe symptoms in adulthood. There does not appear to be a definite correlation between the type, frequency, and severity of symptoms and the eventual prognosis. Patients with severe tics may experience social difficulties and may isolate themselves from others in fear of shocking and embarrassing them. People with Tourette syndrome who have other symptoms such as obsessive compulsive disorder, attention deficit disorder, and self–injurious behavior usually have a poorer prognosis.

Prevention

There is no known way to prevent Tourette syndrome.

Toxic encephalopathy *see* **Delirium**

Toxic epidermal necrolysis

Definition

Toxic epidermal necrolysis is a rare condition that causes large portions of the epidermis, the skin's outermost layer, to detach from the layers of skin below. A reaction to a medication is the primary cause.

Description

Toxic epidermal necrolysis (TEN) begins with **fever**, **cough**, and other nonspecific symptoms, and is soon followed by purplish, bloody-looking lesions on the skin and mucous membranes. These early lesions, typically found on the head, neck, and upper chest, soon merge and blister. Sheets of epidermis then begin to detach from the skin layers below. In time, the entire surface of the skin may be involved, with detachment of 100% of the epidermis.

Causes and symptoms

The main cause of TEN is a severe drug reaction. Some investigators believe there may be additional infectious causes. A severe reaction in transplant patients, called **graft-vs.-host disease**, can also produce TEN. One study reported more than 100 different drugs as causes of TEN. The drugs most commonly implicated, however, include antibacterial **sulfonamides** such as sulfadiazine, **antibiotics** such as aminopenicillins and **cephalosporins**, and anticonvulsants like phenytoin. TEN is extremely rare. Researchers estimate that there are 0.2 cases per million users of aminopenicillins and 4.5 cases per million users of sulfonamides.

Exactly what leads to detachment of the epidermis remains unclear. People with TEN seem to have difficulty metabolizing the offending drug. Some researchers suggest that certain substances that should be cleared from the body instead get deposited on the outer shell of the epidermis, causing an immune response that leads the body to "reject" the skin.

Diagnosis

Diagnosis is made primarily on the appearance and spread of the **skin lesions**, and on a history that includes introduction of a new medication within the previous one to three weeks. A biopsy of the early lesions will confirm the diagnosis. Physicians will consider other potential diseases that cause similar symptoms before reaching a diagnosis of TEN. One is **erythema multiforme**, a recurrent skin disorder that produces lesions similar in appearance to TEN. However, this disorder is not caused by a drug reaction and does not lead to sheet-like shedding of the skin. Another disease, Stevens-Johnson syndrome, is a drug-induced skin disease that some experts believe is really a milder form of TEN. **Staphylococcal scalded skin syndrome** (SSSS) also looks like TEN, but it is caused by a staphylococcal infection. Unlike TEN, which occurs rarely in children, SSSS primarily affects infants, young children, and adults with weakened immune systems.

KEY TERMS

Epidermis—The outermost layer of the skin.

Erythema multiforme—A recurrent skin disorder that produces lesions similar in appearance to TEN, but is not caused by a drug reaction and does not lead to sheet-like shedding of the skin.

Staphylococcal scalded skin syndrome—A disease caused by *Staphylococcus aureus,* in which large sheets of skin may peel away from the body. It most often affects infants, young children, and people with weakened immune systems.

Stevens-Johnson syndrome—A drug-induced skin disease that some experts believe is really a milder form of TEN.

Treatment

There is no specific treatment for TEN. Patients are typically treated in an intensive care unit or in a burn unit and receive treatment similar to that given to patients with major **burns**. With the loss of skin, severe **dehydration** is a major risk, so health care workers will attempt to replace fluids intravenously. Nutritional supplementation from a tube routed through the nose to the stomach may also be contemplated to promote the healing of the skin. Infection is a major risk, so some physicians "paint" the open lesions with topical **antiseptics**. Others use skin grafts taken from cadavers or cultured skin substitutes to cover large open areas until healing can occur. Some investigators believe system **corticosteroids** are useful in the treatment of TEN. But since these medications have also been implicated as a cause in some cases of TEN and are known to supress the immune system, their use should be considered carefully.

Prognosis

About 25-30% of patients with TEN die. Elderly patients, those with extensive skin lesions, and those with **AIDS** have the worst prognosis. Widespread

systemic infection (**sepsis**) is the primary cause of **death**. Survivors, however, will be completely healed in three to four weeks.

Prevention

There is no prevention for TEN. No reliable test can indicate that a specific drug may cause TEN in a specific patient. Some researchers believe skin tests of potentially offending drugs may prove useful in the future.

Richard H. Camer

Toxic shock syndrome

Definition

Toxic shock syndrome (TSS) is an uncommon, but potentially fatal, illness that occurs when poisonous substances (toxins) produced by certain bacteria enter the bloodstream. TSS is a medical emergency and requires immediate medical attention.

Demographics

Although TSS is, in the public mind, most strongly associated with healthy women who used super-absorbent tampons during the 1980s and developed the syndrome, children and men also can develop TSS. At its height between 1980 and 1984, TSS affected 15,000 people in the United States annually. Once the cause of the syndrome was understood and the offending tampons were removed from the market, the rate dropped sharply. Although in 2010, TSS was uncommon (only 1–3 cases per 100,000 population), the rate is increasing, most likely due to an increase in strains of antibiotic-resistant bacteria that can cause the syndrome.

Description

TSS first came to the attention of the public in the late 1970s. Shortly after the introduction of super-absorbent tampons, young women across the United States experienced an epidemic of serious but unexplained symptoms. Thousands went to emergency rooms with high **fever**, **vomiting**, peeling skin, low blood pressure, **diarrhea**, and a rash resembling **sunburn**. The only thing they had in common was that they all were menstruating at the time they felt sick, and all were using tampons, especially super-absorbent products.

Despite the association of TSS and menstruating women, the disease can affect anyone of either sex or any age or race. The infection may occur in children, men, and non-menstruating women who are weakened from surgery, injury, or disease, and who cannot fight off a staphylococcal infection. New mothers also are at higher risk for TSS.

As of 2010, two kinds of toxic shock syndrome were recognized. Traditional toxic shock or TSS is caused by staphylococcus bacteria. Another form of toxic shock caused by streptococcal bacteria was recognized in 1987, It is referred to as Streptococcal toxic shock syndrome or (STSS). STSS is related to the strain of streptococcus nicknamed the "flesh-eating bacterium." It affects only one or two out of every 100,000 Americans. STSS almost never follows a simple **strep throat** infection. Sometimes STSS is referred to as toxic shock-like syndrome or TSLS.

Risk factors

People who are most likely to develop TSS are between the ages of 15 and 35. STSS is most likely to affect people between the ages of 20 and 50. Other risk factors include just having given birth, extended use of packing material to stop blood flow (e.g. tampons, packing to stop a nose bleed), the use of barrier contraceptives (e.g., diaphragm, vaginal sponge, especially if left in a long time) recent surgery, a recent staphylococcal or streptococcal infection and recent varicella (**chickenpox**) infection.

Causes and symptoms

TSS is caused by staphylococcal bacteria, most often a specific strain of *Staphylococcus aureus* found in the nose, mouth, and occasionally the vagina. The bacteria produce a characteristic toxin. In large enough quantities, the toxin enters the bloodstream and causes a potentially fatal infection.

These types of bacteria normally are present either on hands or in the vagina, and it takes an amount of bacteria only the size of a grain of sand to start an infection. Of the 15% of women who carry *Staphylococcus aureus*, only about 5% have the strain that produces the TSS toxin. STSS is caused by streptococcal bacteria, most often a specific strain of *Streptococcus pyogenes*.

TSS begins with 2–3 day period of mild symptoms, then symptoms escalate suddenly, with a high

KEY TERMS

Electrocardiogram (ECG, EKG)—A test that records the electrical activity of the heart using small electrode patches attached to the skin on the chest.

Electrolyte—Salts and minerals that ionize in body fluids. The major human electrolytes are sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^-), phosphate (HPO_4^{2-}), bicarbonate (HCO_3-), and sulfate (SO_4^{2-}). Electrolytes control the fluid balance of the body and are important in muscle contraction, energy generation, and almost all major biochemical reactions in the body.

Shock—A condition in which the amount of blood circulating in the body is inadequate to meet the body's needs. Shock can be caused by certain diseases, serious injury, or blood loss.

Staphylococcus—A genus of bacteria that is commonly found on human skin and mucous membranes.

Streptococcus—A genus of sphere-shaped bacteria that can cause a wide variety of infections.

Toxin—A poisonous protein that is produced by some bacteria. A toxin is less complex than a poison.

fever of 102°F (38.9°C) or above, **vomiting** and watery diarrhea, **headache**, and sunburn-like rash, together with a **sore throat** and body aches. Blood pressure may plummet a day or two after the first symptoms appear. When the blood pressure drops, an individual may become disoriented or go into shock. The kidneys may fail. After these developments, the skin on the hands and feet may peel. Symptoms of STSS are usually more serious and severe than those of TSS, although both variations of the syndrome can be fatal.

Diagnosis

No specific tests will diagnose TSS or STSS. A **complete blood count** (CBC) and blood cultures, blood electrolyte measurements, **urinalysis**, renal (Kidney) function and **liver function tests**, imaging studies, and an electrocardiogram (ECG) may be done to rule out other diseases and to indicate the direction of treatment.

Treatment

TSS and STSS are medical emergencies. Individuals who suspect that they have this syndrome should go to the emergency department immediately.

Individuals will be hospitalized usually in an intensive care unit (ICU), possibly for an extended period. All foreign packing material should be removed from the body as soon as possible. The first step in treatment is to stabilize the individual, which may involve giving oxygen, medications to increase blood pressure, or **kidney dialysis** if the kidney is failing and ventilator support if breathing is impaired. The second part of treatment involves the administration of intravenous (IV) **antibiotics** and sometimes surgery to eliminate the infection. The increasing prevalence of strains of antibiotic-resistant bacteria may make it necessary to use multiple antibiotics to control the infection. The final step of treatment involves, where possible, reversing any damage caused by the bacterial toxins. This may involve surgery to remove dead or damaged tissue.

Prognosis

Untreated TSS/STSS can be fatal. Even with treatment, about 5% of individuals with TSS die and up to 70% of individuals with STSS die. Individuals with diabetes, compromised immune systems, the very young, and the elderly are most likely to die. Rapid treatment increases the chance of survival. Survivors may experience long-term kidney damage, memory and concentration problems, lung damage, and nervous system abnormalities. The syndrome recurs within two months in 30–50% of individuals, although recurrence is generally less severe than the initial infection.

Prevention

Women who wear tampons should wash their hands before inserting the tampon and change tampons often (every 4–6 hours). **Wounds** should be kept clean and **dressings** changed regularly. Some of the more serious complications can be reduced or prevented by seeking emergency medical care as soon as TSS/STSS is suspected. This is not a condition that can be successfully treated with home care or alternative therapies.

Toxoplasmosis

Definition

Toxoplasmosis is an **infectious disease** caused by the one–celled protozoan parasite *Toxoplasma gondii*. Although most individuals do not experience any symptoms, the disease can be very serious, and even fatal, in individuals with weakened immune systems.

Demographics

There is no person–to–person transmission, except from an infected mother to her child in the womb. Approximately six out of 1,000 women contract toxoplasmosis during **pregnancy**. Nearly half of these maternal infections are passed on to the fetus. Known as congenital toxoplasmosis, this form of the disease is acquired at birth by approximately 3,300 infants in the United States every year. The risk of fetal infection is estimated to be between one in 1,000 to one in 10,000. In children born with toxoplasmosis, symptoms may be severe and quickly fatal, or may not appear until several months or even years after birth.

Description

Toxoplasmosis is caused by a one–celled protozoan parasite known as *Toxoplasma gondii*. Cats, the primary carriers of the organism, become infected by eating rodents and birds infected with the organism. Once ingested, the organism reproduces in the intestines of cats, producing millions of eggs known as oocysts, which are excreted in cat feces daily for approximately two weeks. In the United States, it is estimated that approximately 30% of cats have been infected by *T. gondii*. Oocysts are not capable of producing infection until approximately 24 hours after being excreted, but they remain infective in water or moist soil for approximately one year. When cattle, sheep, or other livestock forage through areas with contaminated cat feces, these animals become carriers of the disease. Fruits and vegetables can also become contaminated when irrigated with untreated water that has been contaminated with cat feces. In humans and other animals, the organisms produce thick–walled, dormant structures called cysts in the muscle and other tissues of the body.

Most humans contract toxoplasmosis by eating cyst–contaminated raw or undercooked meat, vegetables, or milk products. Humans can also become infected when they come into contact with *T. gondii* eggs while cleaning a cat's litter box, gardening, or playing in a sandbox, for instance. Once infected, an individual is immune to reinfection. The incubation period or period between infection and the start of the disease ranges from several days to months.

Anyone can be infected by *T. gondii*, but usually only those individuals with weakened immune systems (immunocompromised) develop symptoms of the disease. For them, toxoplasmosis can be severe, debilitating, and fatal. Immunocompromised individuals at risk include those with **AIDS**, **cancer**, or other chronic illnesses.

Causes and symptoms

Healthy individuals do not usually display symptoms. When symptoms do occur, they are usually mild, resembling **infectious mononucleosis**, and include the following:

- enlarged lymph nodes
- muscle pains
- intermittent fever
- general sick feeling

The distinction is made between acquired toxoplasmosis, in which an individual becomes infected, and neonatal congenital toxoplasmosis, in which a fetus is born with the infection because the mother became infected during pregnancy. If a fetus becomes infected early in pregnancy, the disease can cause the fetus to spontaneously abort or be stillborn. If full–term, the infant may die in infancy or suffer from central nervous system lesions. If the mother becomes infected in the last three months of pregnancy, however, the prognosis is good, and the baby may not even display any symptoms.

In adults, if infection continues for an extended period of time, chronic toxoplasmosis can cause an inflammation of the eyes called retinochoroiditis, which can lead to blindness, severe yellowing of the skin and whites of the eyes (**jaundice**), easy bruising, and convulsions.

KEY TERMS

Cyst—The thick–walled dormant form of many organisms.

Immunocompromised—A state in which the immune system is suppressed or not functioning properly.

Oocyst—The egg form of the toxoplasmosis organism.

Protozoan—A single–celled, usually microscopic, organism.

Adults with weakened immune systems have a high risk of developing cerebral toxoplasmosis, including inflammation of the brain (**encephalitis**), one–sided weakness or **numbness**, mood and personality changes, vision disturbances, **muscle spasms**, and severe headaches. If untreated, cerebral toxoplasmosis can lead to **coma** and **death**. This form of encephalitis is the second most common AIDS–related nervous system infection that takes advantage of a person's weakened immune system (opportunistic infection).

Diagnosis

A diagnosis of toxoplasmosis is made based on clinical signs and supporting laboratory results, including visualization of the protozoa in body tissue or isolation in animals and blood tests. Laboratory tests for toxoplasmosis are designed to detect increased amounts of a protein or antibody produced in response to infection with the toxoplasmosis organism. Antibody levels can be elevated for years, however, without active disease.

Treatment

Most individuals who contract toxoplasmosis do not require treatment because their immune systems are able to control the disease. Symptoms are not usually present. Mild symptoms may be relieved by taking over–the–counter medications, such as **acetaminophen** (Tylenol) and ibuprofen (Motrin, Advil). **Sore throat** lozenges and rest may also ease the symptoms.

Although the treatment of women infected with toxoplasmosis during pregnancy is controversial, most physicians feel that treatment is justified. Transmission of toxoplasmosis from the mother to the fetus may be prevented if the mother takes the antibiotic spiramycin. Later in a pregnancy, if the fetus has contracted the disease, treatment with the antibiotic pyrimethamine (Daraprim, Fansidar) or **sulfonamides** may be effective. Babies born with toxoplasmosis who show symptoms of the disease may be treated with pyrimethamine, the sulfa drug sulfadiazine (Microsulfon), and folinic acid (an active form of **folic acid**).

AIDS patients who have not been infected may be given a drug called TMP/SMX (Bactrim or Septra) to prevent toxoplasmosis infection. To treat cases of toxoplasmosis in immunocompromised AIDS patients, a combination of pyrimethamine and a sulfa–based drug, either sulfadiazine or clindamycin (Cleocin), have been used together and can be effective in treating this disease. Other antibiotic combinations and dosing schedules are still being investigated. Physicians have reported success in alleviating symptoms by using trimethoprim–sulfamethoxazole (Proloprim or Trimpex) or dapsone (DDS) plus pyrimethamine. These drugs can produce side effects, such as allergic reaction, **itching**, **rashes**, and **nausea**, and patients must be monitored closely.

Prognosis

Prognosis is poor when congenital toxoplasmosis is acquired during the first three months of pregnancy. Afflicted children die in infancy or suffer damage to their central nervous systems that can result in physical and **mental retardation**. Infection later in pregnancy usually results in only mild symptoms, if any. The prognosis for acquired toxoplasmosis in adults with strong immune systems is excellent. The disease often disappears by itself after several weeks. However, the prognosis for immunodeficient patients is not as positive. These patients often relapse when treatment is stopped. The disease can be fatal to immunocompromised patients, especially AIDS patients, and particularly if not treated. As a result, immunocompromised patients are typically placed on anti–toxoplasmosis drugs for the rest of their lives.

Prevention

There are no drugs that can eliminate *T. gondii* cysts in animal or human tissues. Humans can reduce their risks of developing toxoplasmosis by practicing the following:

- freezing (to 10.4°F/–12°C) and cooking foods to an internal temperature of 152°F/67°C will kill the cyst
- practicing sanitary kitchen techniques, such as washing utensils and cutting boards that come into contact with raw meat
- keeping pregnant women and children away from household cats and cat litter
- disposing of cat feces daily, because the oocysts do not become infective until after 24 hours

- helping cats to remain free of infection by feeding them dry, canned, or boiled food and by discouraging hunting and scavenging
- washing hands after outdoor activities involving soil contact and wearing gloves when gardening

Trabeculectomy

Definition

Trabeculectomy is a surgical procedure that removes part of the trabeculum in the eye to relieve pressure caused by glaucoma.

Purpose

Glaucoma is a disease that injures the optic nerve, causing progressive loss of vision. Presently, glaucoma is a major cause of blindness in the United States If caught early, glaucoma-related blindness is easily prevented. However, since it does not produce symptoms until late in its cycle, periodic tests for the disease are necessary.

KEY TERMS

Cornea—Transparent film that covers the iris and pupil.

Iris—Colored part of the eye, which is suspended in aqueous humor and perforated by the pupil.

Sclera—White, outer coating of the eyeball.

Trabeculoplasty—Laser surgery that creates perforations in the trabeculum, to drain built up aqueous humor and relieve pressure.

Trabeculum—Tissue that is a drainage point for aqueous humor in the eye.

Glaucoma is usually associated with an increase in the pressure inside the eye. This increase occurs in front of the iris in a fluid called the aqueous humor. Aqueous humor is supposed to exit through tiny channels between the iris and the cornea, in an area called the trabeculum. When the trabeculum is blocked, pressure from the build up of aqueous humor either increases rapidly with considerable **pain** and redness, or, as in most cases, the pressure builds slowly with no symptoms until much of the vision is lost. Trabeculectomy is the last treatment employed for either type of glaucoma. It is used only after medications and laser trabeculoplasty (less invasive procedure that uses a laser to open the blocked trabeculum) have failed to alleviate the pressure.

Description

A trabeculectomy involves removing a tiny piece of the eyeball right at the place where the cornea connects to the sclera (the white part), and creating a flap to allow fluid to escape the anterior chamber without deflating the eye. Along with that tiny piece of cornea and sclera comes a piece of the iris. The whole area is called the trabeculum. Fluid can then flow out onto the surface of the eye and be absorbed by the conjunctiva, the transparent membrane that lines the sclera and the eyelids. Sometimes, an additional piece is taken out of the iris so that anterior chamber fluid can also flow backward into the vitreous part of the eye. This procedure is called an iridectomy.

Preparation

The procedure and its benefits and possible complications are fully explained. Antiglaucoma drugs are prescribed before surgery. Added pressure on the eye caused from coughing or sneezing should be avoided.

Aftercare

Eye drops, and perhaps patching, will be needed until the eye is healed. The pressure inside the eye will still be monitored. Immediately following the procedure, the patient may experience blurred vision.

Risks

Infection and bleeding are risks of any surgery. Scarring can cause the drainage to stop. A third of patients with trabeculectomies will develop **cataracts**.

Tracheoesophageal fistula

Definition

Tracheoesophageal **fistula** (TEF) is commonly a birth defect, with the trachea connected to the esophagus. In most cases, the esophagus is discontinuous, causing immediate feeding difficulties. TEFs may develop in adult life, secondary to the invasion of **cancer** in the area. In addition, TEFs may be deliberately constructed with surgery to aid talking in a patient who has the larynx removed (a **laryngectomy**).

Description

The trachea, or windpipe, carries air to the lungs. The esophagus carries food to the stomach. Sometimes during development, these two tubes do not separate completely, but remain connected by a short passage. When this happens, air enters the gastrointestinal system, causing the bowels to distend, and mucus is breathed into the lungs causing aspiration **pneumonia** and breathing problems.

Most tracheoesophageal fistulas are diagnosed when a child is born. There are three types. In 85–90% of tracheoesophageal fistulas, the top part of the esophagus ends in a blind sac, and the lower part inserts into the trachea. In the second type, the upper part of the esophagus is connected directly to the trachea, while the lower part ends in a pouch. In a rare type of fistula called an H type, both the esophagus and trachea are complete, but they are connected. This is the most difficult type of tracheoesophageal fistula to diagnose, because both eating and breathing are possible.

KEY TERMS

Endoscopy—A procedure in which an instrument containing a camera and a light source is inserted into the gastrointestinal tract so that the physician can visually inspect the gastrointestinal system.

Gastrostomy tube—Stomach tube for feeding.

Laryngectomy—Surgical removal of the larynx to treat cancer.

Causes and symptoms

Tracheoesophageal fistulas arise as a developmental abnormality. At birth, the infant has difficulty swallowing. Eating produces severe coughing spells that interfere with breathing. Aspiration pneumonia can develop from fluid breathed into the lungs.

Small H type fistulas may go undiagnosed until later in life. Symptoms of an H type fistula include frequent pulmonary infections and bouts of abdominal bloating.

Diagnosis

Diagnosis that the esophagus is interrupted is confirmed by the inability to insert a **nasogastric suction** tube into the stomach. The exact type and location of the fistula can be determined using a radiopaque catheter, which allows pictures to be taken of the esophagus. X rays may show air in the bowels. **Endoscopy** often fails to located the fistula if it is small.

Treatment

Babies with all but H type fistulas are unlikely to survive without surgical separation and repair of the trachea and the esophagus. Surgery cannot always be performed immediately because of **prematurity**, the presence of other **birth defects**, or complications from aspiration pneumonia. It is usually done at a hospital that has special facilities for treating seriously ill newborns.

While awaiting surgery, the infant's condition is stabilized. Preoperative care concentrates on avoiding aspiration pneumonia and includes:

- elevating the head to avoid reflux and aspiration of the stomach contents
- using a suction catheter to continuously removed mucus and saliva that could be inhaled

- when necessary, placement of a gastrostomy tube
- withholding feeding by mouth

When surgery is performed, the esophagus is reconnected to make it continuous and separate from the trachea. If the two ends of the esophagus are too far apart to be reattached, a piece of tissue from the large intestine is used to join the parts.

Prognosis

Infants who have tracheoesophageal fistula often have other birth defects that affect their recovery. Even when the esophagus is successfully separated and reattached, many infants have difficulty swallowing, because the contractility of the esophagus is impaired. Infants may also have problems with gastroesophageal reflux, in which the acidic contents of the stomach back up into the bottom of the esophagus and cause ulcers and scarring.

Prevention

Tracheoesophageal fistulas are not preventable birth defects.

Tracheostomy *see* **Tracheotomy**

Tracheotomy

Definition

A tracheotomy is a surgical procedure that opens up the windpipe (trachea). It is performed in emergency situations, in the operating room, or at bedside of critically ill patients. The term tracheostomy is sometimes used interchangeably with tracheotomy. Strictly speaking, however, tracheostomy usually refers to the opening itself while a tracheotomy is the actual operation.

Purpose

A tracheotomy is performed if enough air is not getting to the lungs, if the person cannot breathe without help, or is having problems with mucus and other secretions getting into the windpipe because of difficulty swallowing. There are many reasons why air cannot get to the lungs. The windpipe may be blocked by a swelling; by a severe injury to the neck, nose, or mouth; by a large foreign object; by **paralysis** of the throat muscles; or by a tumor. The patient may be in a **coma**, or need a ventilator to pump air into the lungs for a long period of time.

Demographics

Emergency tracheotomies are performed as needed in any person requiring one.

Description

Emergency tracheotomy

There are two different procedures that are called tracheotomies. The first is done only in emergency situations and can be performed quite rapidly. The emergency room physician or surgeon makes a cut in a thin part of the voice box (larynx) called the cricothyroid membrane. A tube is inserted and connected to an oxygen bag. This emergency procedure is sometimes called a cricothyroidotomy.

Surgical tracheotomy

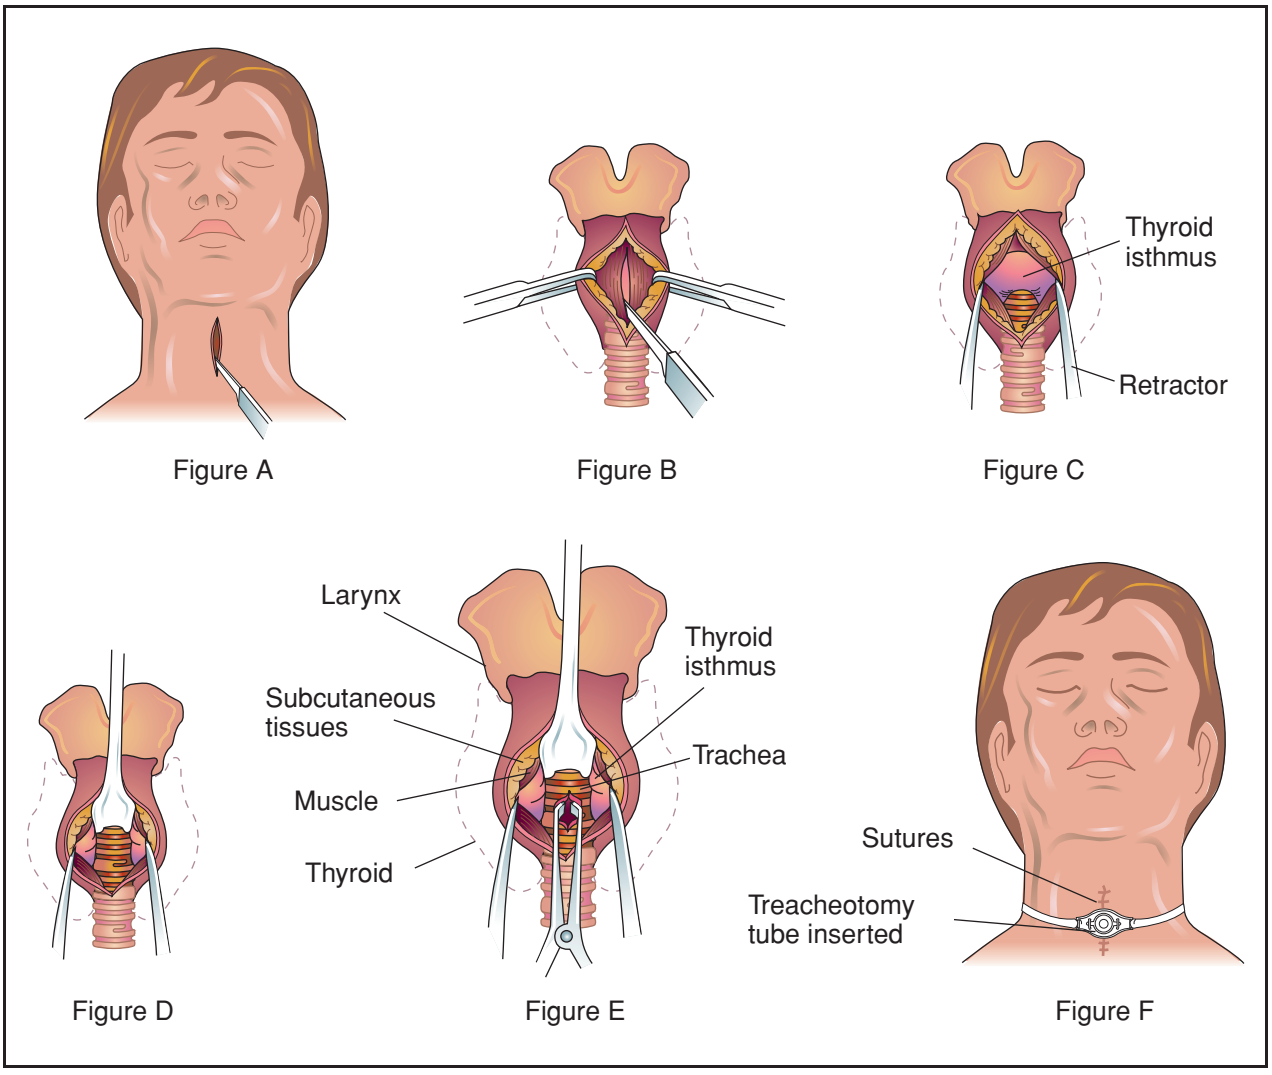
The second type of tracheotomy takes more time and is usually done in an operating room. The surgeon first makes a cut (incision) in the skin of the neck that lies over the trachea. This incision is in the lower part of the neck between the Adam's apple and top of the breastbone. The neck muscles are separated and the thyroid gland, which overlies the trachea, is usually cut down the middle. The surgeon identifies the rings of cartilage that make up the trachea and cuts into the tough walls. A metal or plastic tube, called a tracheotomy tube, is inserted through the opening. This tube acts like a windpipe and allows the person to breathe. Oxygen or a mechanical ventilator may be hooked up to the tube to bring oxygen to the lungs. A dressing is placed around the opening. Tape or stitches (sutures) are used to hold the tube in place.

After a nonemergency tracheotomy, the patient usually stays in the hospital for three to five days, unless there is a complicating condition. It takes about two weeks to recover fully from the surgery.

Diagnosis/Preparation

Emergency tracheotomy

In the emergency tracheotomy, there is no time to explain the procedure or the need for it to the patient. The patient is placed on his or her back with face



Tracheotomy is a surgical procedure in which an opening is made in the windpipe or trachea. As shown in the illustration above, the physician or surgeon will follow these steps in performing this procedure: Figure A: A vertical incision is made through the skin. Figure B: Another incision is made through the subcutaneous tissues and muscles of the neck. Figure C: The neck muscles are separated using retractors. Figure D: The thyroid isthmus is either cut or retracted. Figure E: The surgeon identifies the rings of cartilage that make up the trachea and cuts into the walls. Figure F: A metal or plastic tube is inserted into the opening and sutures are used to hold the tube in place. *(Illustration by Electronic Illustrators Group. Reproduced by permission of Gale, a part of Cengage Learning.)*

upward (supine), with a rolled-up towel between the shoulders. This positioning of the patient makes it easier for the doctor to feel and see the structures in the throat. A local anesthetic is injected across the cricothyroid membrane.

Nonemergency tracheotomy

In a nonemergency tracheotomy, there is time for the doctor to discuss the surgery with the patient, to explain what will happen and why it is needed. The patient is then put under **general anesthesia**. The neck area and chest are then disinfected and surgical drapes are placed over the area, setting up a sterile surgical field.

Aftercare

Postoperative care

A **chest x ray** is often taken, especially in children, to check whether the tube has become displaced or if complications have occurred. The doctor may prescribe **antibiotics** to reduce the risk of infection. If the patient can breathe without a ventilator, the room is

KEY TERMS

Cartilage—A tough, fibrous connective tissue that forms various parts of the body, including the trachea and larynx.

Cricothyroidotomy—An emergency tracheotomy that consists of a cut through the cricothyroid membrane to open the patient's airway as fast as possible.

Larynx—A structure made of cartilage and muscle that connects the back of the throat with the trachea. The larynx contains the vocal cords.

Trachea—The tube that leads from the larynx or voice box to two major air passages that bring oxygen to each lung. The trachea is sometimes called the windpipe.

Ventilator—A machine that helps patients to breathe. It is sometimes called a respirator.

humidified; otherwise, if the tracheotomy tube is to remain in place, the air entering the tube from a ventilator is humidified. During the hospital stay, the patient and his or her family members will learn how to care for the tracheotomy tube, including suctioning and clearing it. Secretions are removed by passing a smaller tube (catheter) into the tracheotomy tube.

It takes most patients several days to adjust to breathing through the tracheotomy tube. At first, it will be hard even to make sounds. If the tube allows some air to escape and pass over the vocal cords, then the patient may be able to speak by holding a finger over the tube. Special tracheostomy tubes are also available that facilitate speech.

The tube will be removed if the tracheotomy is temporary. Then the wound will heal quickly and only a small scar may remain. If the tracheotomy is permanent, the hole stays open and, if it is no longer needed, it will be surgically closed.

Home care

After the patient is discharged, he or she will need help at home to manage the tracheotomy tube. Warm compresses can be used to relieve **pain** at the incision site. The patient is advised to keep the area dry. It is recommended that the patient wear a loose scarf over the opening when going outside. He or she should also avoid contact with water, food particles, and powdery substances that could enter the opening and cause serious breathing problems. The doctor may prescribe pain medication and antibiotics to minimize the risk of infections. If the tube is to be kept in place permanently, the patient can be referred to a speech therapist in order to learn to speak with the tube in place. The tracheotomy tube may be replaced four to 10 days after surgery.

Patients are encouraged to go about most of their normal activities once they leave the hospital. Vigorous activity is restricted for about six weeks. If the tracheotomy is permanent, further surgery may be needed to widen the opening, which narrows with time.

Risks

Immediate risks

There are several short-term risks associated with tracheotomies. Severe bleeding is one possible complication. The voice box or esophagus may be damaged during surgery. Air may become trapped in the surrounding tissues or the lung may collapse. The tracheotomy tube can be blocked by **blood clots**, mucus, or the pressure of the airway walls. Blockages can be prevented by suctioning, humidifying the air, and selecting the appropriate tracheotomy tube. Serious infections are rare.

Long-term risks

Over time, other complications may develop following a tracheotomy. The windpipe itself may become damaged for a number of reasons, including pressure from the tube, infectious bacteria that forms scar tissue, or friction from a tube that moves too much. Sometimes the opening does not close on its own after the tube is removed. This risk is higher in tracheotomies with tubes remaining in place for 16 weeks or longer. In these cases, the wound is surgically closed. Increased secretions may occur in patients with tracheostomies, which require more frequent suctioning.

High-risk groups

The risks associated with tracheotomies are higher in the following groups of patients:

- children, especially newborns and infants
- smokers
- alcoholics
- obese adults
- persons over 60
- persons with chronic diseases or respiratory infections
- persons taking muscle relaxants, sleeping medications, tranquilizers, or cortisone

Normal results

Normal results include uncomplicated healing of the incision and successful maintenance of long-term tube placement.

Morbidity and mortality rates

The overall risk of **death** from a tracheotomy is less than 5%.

Alternatives

For most patients, there is no alternative to emergency tracheotomy. Some patients with pre-existing neuromuscular disease (such as ALS or **muscular dystrophy**) can be sucessfully managed with emergency noninvasive ventilation via a face mask, rather than with tracheotomy. Patients who receive nonemergency tracheotomy in preparation for mechanical ventilation may often be managed instead with noninvasive ventilation, with proper planning and education on the part of the patient, caregiver, and medical staff.

Trachoma

Definition

Trachoma, which is also called granular **conjunctivitis** or Egyptian ophthalmia, is a contagious, chronic inflammation of the mucous membranes of the eyes, caused by *Chlamydia trachomatis*. It is characterized by swelling of the eyelids, sensitivity to light, and eventual scarring of the conjunctivae and corneas of the eyes.

A close-up of a human eye with trachoma. Trachoma is caused by *Chlamydia trahomatis* and commonly results in blindness if left untreated. *(Custom Medical Stock Photo, Inc. Reproduced by permission.)*

Description

Trachoma is a major cause of blindness in the world. It is found in the Far East, as well as countries with desert climates. In the United States, it is most common among certain Native Americans and in parts of Appalachia. The infection is highly contagious in its early stages. Blindness results from recurrent untreated infections.

The conjunctiva is the clear mucous membrane that lines the inside of the eyelid and covers the white part (sclera) of the eye. Conjunctivitis is an inflammation of the conjunctiva.

Causes and symptoms

Trachoma is caused by *C. trachomatis*, a parasitic organism closely related to bacteria. It is transmitted by insects, by hand-to-eye contact, or by the sharing of infected handkerchiefs or towels. The incubation period is about a week.

The early symptoms of trachoma include the development of follicles (small sacs) on the conjunctivae of the upper eyelids, **pain**, swollen eyelids, a discharge, tearing, and sensitivity to light. If the infection is not treated, the follicles develop into large yellow or gray pimples, and small blood vessels develop inside the cornea. In most cases, both eyes are infected.

Repeated infections eventually lead to contraction and turning-in of the eyelids, scarring of the corneas and conjunctivae, eventual blockage of the tear ducts, and blindness.

KEY TERMS

Conjunctivitis—Inflammation of the conjunctivae, which are the mucous membranes covering the white part of the eyeball (sclera) and lining the inside of the eyelids.

Cornea—The transparent front part of the eye that allows light to enter.

Ophthalmia—Inflammation of the eye. Usually severe and affecting the conjunctiva. Trachoma is sometimes called Egyptian ophthalmia.

Diagnosis

Diagnosis is based on a combination of the patient's history (especially living or traveling in areas with high rates of trachoma) and examination of the eyes. The doctor will look for the presence of follicles or scarring. He or she will take a small sample of cells from the patient's conjunctivae and examine them, following a procedure called Giemsa staining, to confirm the diagnosis.

Treatment

Treatment of early-stage trachoma consists of four to six weeks of antibiotic treatment with tetracycline, erythromycin, or **sulfonamides**. **Antibiotics** should be given without waiting for laboratory test results. Treatment may combine oral medication with antibiotic ointment applied directly to the eyes. A single-dose treatment with azithromycin is an alternative method. **Tetracyclines** should not be given to pregnant women or children below the age of seven years.

Patients with complications from untreated or repeated infections are treated surgically. Surgery can be used for **corneal transplantation** or to correct eyelid deformities.

Prognosis

The prognosis for full recovery is excellent if the patient is treated promptly. If the infection has progressed to the stage of follicle development, prevention of blindness depends on the severity of the follicles, the presence of additional bacterial infections, and the development of scarring.

Prevention

There are vaccines available that offer temporary protection against trachoma, but there is no permanent immunization. Prevention depends upon good hygiene and public health measures:

- Seek treatment immediately if a child shows signs of eye infection, and minimize his or her contact with other children.
- Teach children to wash hands carefully before touching their eyes.
- Protect children from flies or gnats that settle around the eyes.
- If someone has trachoma (or any eye infection), do not share towels, pillowcases, etc; wash items well.
- If medications are prescribed, follow the doctor's instructions carefully.

Traction

Definition

Traction is the use of a pulling force to treat muscle and skeleton disorders.

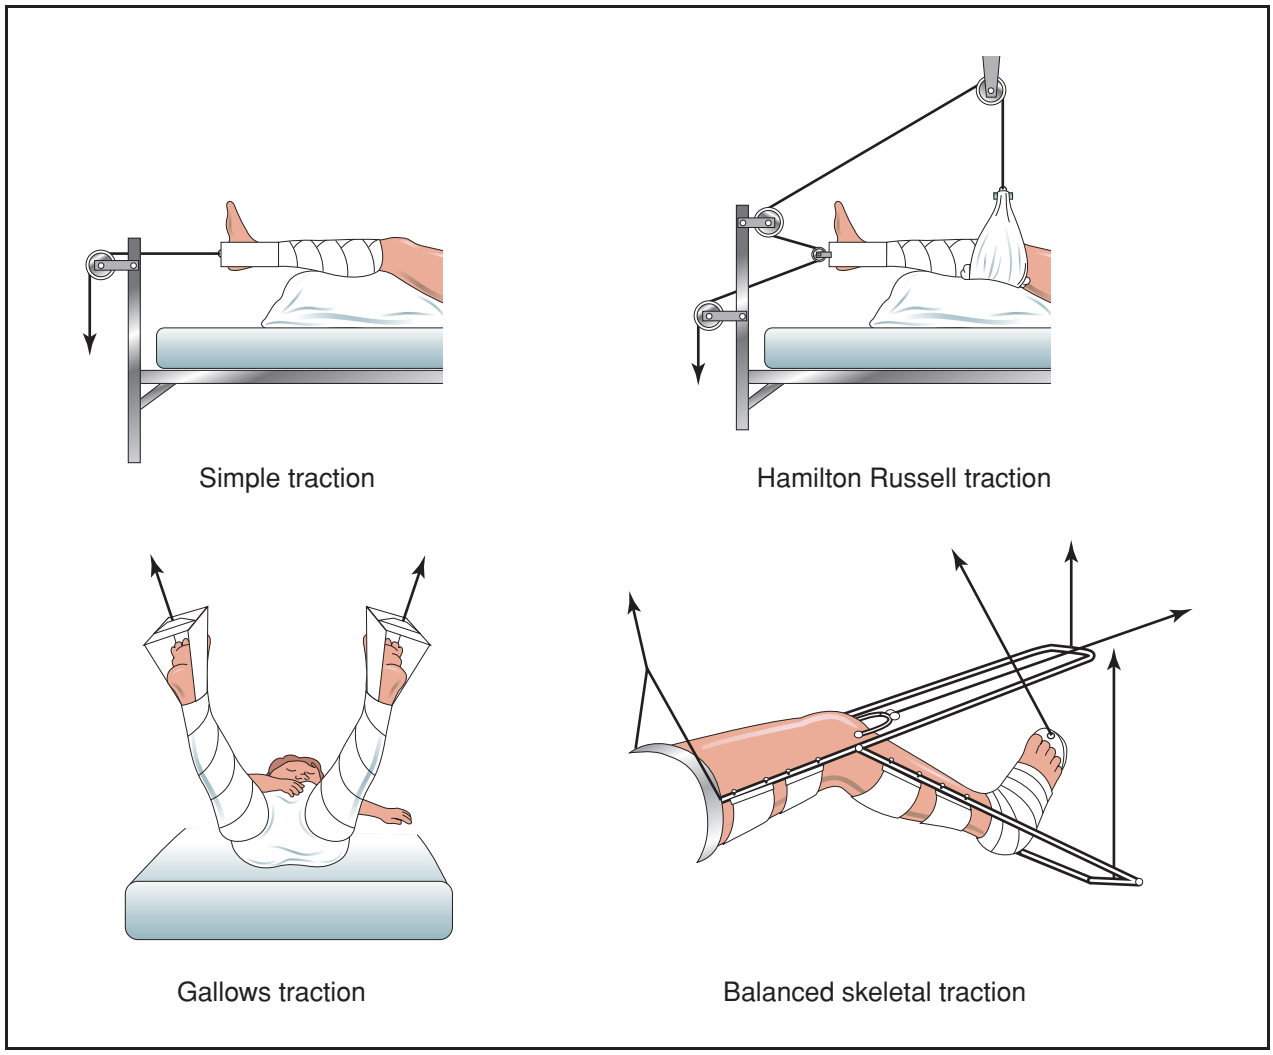
Purpose

Traction is usually applied to the arms and legs, the neck, the backbone, or the pelvis. It is used to treat **fractures**, **dislocations**, and long-duration **muscle spasms**, and to prevent or correct deformities. Traction can either be short-term, as at an accident scene, or long-term, when it is used in a hospital setting.

Traction serves several purposes:

- it aligns the ends of a fracture by pulling the limb into a straight position
- it ends muscle spasm
- it relieves pain
- it takes the pressure off the bone ends by relaxing the muscle

There are two main types of traction: skin traction and skeletal traction. Within these types, many specialized forms of traction have been developed to address problems in particular parts of the body. The application of traction is an exacting technique that requires training



Traction refers to the use of a pulling force and special devices, such as a cast or splint, to treat muscle and skeletal disorders. It is used to treat fractures, dislocations, and long-duration muscle spasms, and to prevent or correct deformities. The illustration above features several commonly used forms of traction. *(Illustration by Electronic Illustrators Group. Reproduced by permission of Gale, a part of Cengage Learning.)*

and experience, since incorrectly applied traction can cause harm.

Positioning the extremity so that the angle of pull brings the ends of the fracture together is essential. Elaborate methods of weights, counterweights, and pulleys have been developed to provide the appropriate force while keeping the bones aligned and preventing muscle spasm. The patient's age, weight, and medical condition are all taken into account when deciding on the type and degree of traction.

Precautions

People who are suffering from skin disorders or who are allergic to tape should not undergo skin traction, because the application of traction will aggravate their condition. Likewise, circulatory disorders or **varicose veins** can be aggravated by skin traction. People with an inflammation of the bone (**osteomyelitis**) should not undergo skeletal traction.

Description

Skin traction

Skin traction uses five-to seven-pound weights attached to the skin to indirectly apply the necessary pulling force on the bone. If traction is temporary, or if only a light or discontinuous force is needed, then skin traction is the preferred treatment. Because the procedure is not invasive, it is usually performed in a hospital bed.

Weights are attached either through adhesive or nonadhesive tape, or with straps, boots, or cuffs. Care must be taken to keep the straps or tape loose enough to prevent swelling and allow good circulation to the part of the limb beyond the spot where the traction is applied. The amount of weight that can be applied through skin traction is limited because excessive weight will irritate the skin and cause it to slough off.

Specialized forms of skin traction have been developed to address specific problems. Dunlop's traction is used on children with certain fractures of the upper arm, when the arm must be kept in a flexed position to prevent problems with the circulation and nerves around the elbow. Pelvic traction is applied to the lower spine, with a belt around the waist. Buck's skin traction is used to treat **knee injuries** other than fractures. The purpose of this traction is to stabilize the knee and reduce muscle spasm.

Skeletal traction

Skeletal traction is performed when more pulling force is needed than can be withstood by skin traction; or when the part of the body needing traction is positioned so that skin traction is impossible. Skeletal traction uses weights of 25-40 pounds.

Skeletal traction requires the placement of tongs, pins, or screws into the bone so that the weight is applied directly to the bone. This is an invasive procedure that is done in an operating room under general, regional, or **local anesthesia**.

Correct placement of the pins is essential to the success of the traction. The pin can be kept in place several months, and must be kept clean to prevent infection. Once the hardware is in place, pulleys and weights are attached to wires to provide the proper pull and alignment on the affected part.

Specialized forms of skeletal traction include cervical traction used for fractures of the neck vertebrae; overhead arm traction used for certain types of upper arm fractures; and tibia pin traction used for some fractures of the femur, hip, or pelvis.

Preparation

X rays are done prior to the application of both forms of traction, and may be repeated during treatment to assure that the affected parts are staying in alignment and healing properly. Since the insertion of the anchoring devices in skeletal traction is a surgical procedure, standard preoperative blood and urine testing are done, and the patient may meet with an anesthesiologist to discuss any health conditions that might affect the administration of anesthesia.

Aftercare

Aftercare for skin traction involves making sure the limb stays aligned, and caring for the skin so that it does not become sore and irritated. The patient should also be alert to any swelling or **tingling** in the limb that would suggest that the limb has been wrapped too tightly.

Aftercare for skeletal traction is more complex. The patient is likely to be immobile for an extended period. Deep breathing exercises are taught so that respiratory function is maintained during this time of little activity. Patients are also encouraged to do range-of-motion exercises with the unaffected parts of the body. The patient is taught how to use a trapeze (an overhead support bar) to shift on and off a bedpan, since it is not possible to get up to use the toilet. In serious injuries, traction may be continued for several months until healing is complete.

Risks

The main risks associated with skin traction are that the traction will be applied incorrectly and cause harm, or that the skin will become irritated. There are more risks associated with skeletal traction. Bone inflammation may occur in response to the introduction of foreign material into the body. Infection can occur at the pin sites. If caught early, infection can be treated with **antibiotics**, but if severe, it may require removal of the pin.

Both types of traction have complications associated with long periods of immobility. These include the development of bed sores, reduced respiratory function, urinary problems, and circulatory problems. Occasionally, fractures fail to heal. Being confined to traction for a long period can take a an emotional toll on the patient, also.

Normal results

When correctly applied, traction generally produces very good, if slow, results.

Traditional Chinese medicine

Definition

Traditional Chinese medicine (TCM) is an ancient and still very vital holistic system of health and healing, based on the notion of harmony and balance, and employing the ideas of moderation and prevention.

Purpose

TCM is a complete system of health care with its own unique theories of anatomy, health, and treatment. It emphasizes diet and prevention and using **acupuncture**, herbal medicine, massage, and **exercise**; and focuses on stimulating the body's natural curative powers.

Precautions

In situations of severe trauma, TCM should not be substituted for contemporary modern trauma practice; it is most useful as an adjunct to the healing regimen. TCM is not the first line of treatment for bacterial infection or **cancer**, but may usefully complement contemporary medical treatment for those conditions.

Description

In theory and practice, traditional Chinese medicine is completely different from Western medicine, both in terms of considering how the human body works and how illness occurs and should be treated. As a part of a continuing system that has been in use for thousands of years, it is still employed to treat over one-quarter of the world's population. Since the earliest Chinese physicians were also philosophers, their ways of viewing the world and human beings role in it affected their medicine. In TCM, both philosophically and medically, moderation in all things is advocated, as is living in harmony with nature and striving for balance in all things. Prevention is also a key goal of Chinese medicine, and much emphasis is placed on educating the patient to live responsibly. The Chinese physician also is more of an advisor than an authority; he or she believes in treating every patient differently, based on the notion that one does not treat the disease or condition but rather the individual patient. Thus two people with the same complaint may be treated entirely differently, if their constitutions and life situations are dissimilar. Disease is also considered to be evidence of the failure of preventive health care and a falling out of balance or harmony.

There is some confusion in the West about the fundamental philosophical principles upon which traditional Chinese medicine is based – such as the concept of yin and yang, the notion of five elements (wood, fire, earth, metal and water), and the concept of *chi*–yet each can be explained in a way that is understandable to Westerners.

Yin and yang describe the interdependent relationship of opposing but complementary forces believed to be necessary for a healthy life. Basically, the goal is to maintain a balance of yin and yang in all things.

The five elements, or five phase theory, is also grounded in the notion of harmony and balance. The concept of *chi*, which means something like "life force" or "energy," is perhaps most different from Western ideas. TCM asserts that *chi* is an invisible energy force that flows freely in a healthy person, but is weakened or blocked when a person is ill. Specifically, the illness is a result of the blockage, rather than the blockage being the result of the illness.

Besides these philosophical concepts that differ considerably from infection-based principles of medicine and health, the methods employed by traditional Chinese medicine are also quite different. If allopathic Western practitioners could be described as interventionist and dependent on synthetic pharmaceuticals, TCM methods are mostly natural and noninvasive. For example, where Western physicians might employ surgery and **chemotherapy** or radiation for a cancer patient, a TCM physician might use acupuncture and dietary changes. TCM believes in "curing the root" of a disease and not merely in treating its symptoms.

Another major difference is how the patient is regarded. In Western medicine, patients with similar complaints or diseases, usually will receive virtually the same treatment. In TCM however, the physician treats the patient and not the condition, believing that identical diseases can have entirely different causes. In terms of the principles upon which it is based and the methods used, traditional Chinese medicine, therefore, is considered by many in the West to be a radically different system of health care.

To some in the Western world, this very strangeness is the reason why it might be attractive. To others, tired of what they perceive as their physician's perfunctory, analytical, and sometimes cold manner, TCM offers a more humane, patient-

oriented approach that encourages a high degree of practitioner-patient interaction and is not overly dependent on technology.

For example, during a consultation with a TCM practitioner, the patient will receive a considerable amount of time and attention. During the important first visit, the practitioner will conduct four types of examinations, all extremely observational and all quite different from what patients usually experience.

First, the practitioner will ask many questions, going beyond the typical patient history to inquire about such particulars as eating and bowel habits or sleep patterns. Next, the physician looks at the patient, observing his or her complexion and eyes, while also examining the tongue very closely, believing that it is a barometer of the body's health and that different areas of the tongue can reflect the functioning of different body organs. After observing, they listen to the patient's voice or **cough** and then smell his or her breath, body odor, urine, and even bowel movements. Finally, the practitioner touches the patient, palpating his or her abdomen and feeling the wrist to take up to six different pulses. It is through these different pulses that the well-trained practitioner can diagnose any problem with the flow of the all-important *chi*. Altogether, this essentially observational examination will lead the physician to diagnose or decide the patient's problem. This diagnosis is very different from one in contemporary Western medicine. No blood or urine samples are tested in a laboratory. The key to this technique lies in the experience and skill of the practitioner.

After making a diagnosis, the physician will suggest a course of treatment from one or all of the available TCM methods. These fall into four main categories: herbal medicine, acupuncture, dietary therapy, and massage and exercise. A typical TCM prescription consists of a complex variety of many different herbal and mineral ingredients. Chinese herbal remedies are intended to assist the body's own systems so that eventually the patient can stop taking them and never becomes dependent on them. Herbal formulas are usually given as teas, which differ according to the patient.

Other common techniques used in a TCM prescription are as follows:

- Acupuncture is based on the notion that the body's vital energy force, *chi*, travels through known channels or "meridians." The acupuncturist inserts tiny, thin sterile needles at particular, selected points on the body to unblock or correct the flow of energy. These needles are hardly felt as they are inserted and are left in place for 15 to 20 minutes. Some patients report immediate improvement, others feel exhilarated, while some feel like sleeping. In some cases, patients say their condition worsens before it improves. No contemporary scientific explanation exists as to how or why acupuncture works.
- Moxibustion is a variation sometimes employed. Moxibustion is the slow burning on or over the body of special herbal "cones." These are placed on specific acupoints and provide penetrating, relaxing heat.
- Massage is often recommended, and a deep finger pressure technique known as acupressure is often used to promote the proper flow of *chi*.
- Diet is considered essential to good health, and what might be called "kitchen medicine" is just another aspect of herbalism. One example is a delicious DQ black bean soup that is traditionally eaten by women in China after childbirth and each menstrual cycle.
- Therapeutic exercises are sometimes prescribed as well. In both the exact and flowing movements of tai chi, and the breathing techniques of Qi Dong exercise is considered essential to relieving stress and promoting the smooth flow of *chi*.

As a system of total health care, TCM is prepared to deal with any physical or mental problem, condition, or disease. However, unlike Western medicine at its best, TCM is not able to render the kind of emergency crisis intervention that saves lives during physical traumas. Nonetheless, it works best at achieving its goal of practicing preventive medicine. It has proven effective in treating many types of aches and pains and in helping people with depression and **fatigue**, as well as circulation and digestive problems. Overall, its emphasis on good

KEY TERMS

Allopathic—Pertaining to conventional medical treatment of disease symptoms that uses substances or techniques to oppose or suppress the symptoms.

Anatomy—The science of the body structure of an organism and its parts.

Holistic—That which pertains to the entire person, including the mind, body, and spirit.

Palpate—To examine the body by touching or pressing with the fingers or the palm of the hand.

Pharmaceutical—Pertaining to drugs.

Therapeutic—Curative or healing.

Trauma—Injury or damage to the body.

diet and exercise, as well as on individual responsibility and moderation in all things, suggest that it is grounded in fundamentally sound principles.

Risks

In the hands of a qualified practitioner, TCM is very safe. However, there is a small chance of not only getting an infection from acupuncture, but also that an existing infection could be spread to other parts of the body by increased blood flow and circulation.

Normal results

Traditional Chinese medicine seeks to harmonize and rebalance the entire human system rather than to treat just symptoms. Since proper internal balance is considered to be the key to human health, TCM strives to cure disease by restoring that balance and therefore allowing the body to repair itself. Its continuing medical goal is to detect and correct abnormalities before they cause permanent physical damage.

Leonard C. Bruno, PhD

MILTON TRAGER (1909–1997)

Milton Trager was a medical doctor and a somatic educator, specializing in body learning. He was a contemporary of F. Matthias Alexander, Moshe Feldenkrais, and Ida Rolf.

As a young man in the 1920s, he occupied himself with gymnastics and boxing. Through his intensely physical pursuits, he arrived at his self-taught body learning theories. The techniques that he nurtured emphasized body control over strength, prowess, and endurance. For example, in striving to leap as high as possible, Trager focused his concentration on landing as softly as possible. He obtained a degree in physical medicine before serving in the military during World War II.

Upon his return, Trager funded his medical school education with his GI benefits. He established a private practice and spent the ensuing 50 years refining his body learning techniques and assisting afflicted individuals in the process. When Trager's father was stricken with sciatic pain, Trager learned to relieve the spasms by hand. In time he learned to alleviate the symptoms of polio victims and others who suffered from muscle spasms.

Trager established the Trager Institute in the 1970s to propagate the techniques that he had developed. By the year 2000, an estimated 2,000 students and practitioners had embraced the Trager Approach.

Trager lived with his wife, Emily, in Southern California at the time of his death in January 1997.

Trager psychophysical integration

Definition

Trager psychophysical integration therapy, also known as the Tragerwork system of physical integration, is a combination of hands-on tissue mobilization, relaxation, and movement reeducation called Mentastics. The underlying principle of psychophysical integration is that clients learn to be lighter, easier, and freer by experiencing lightness, ease, and freedom of movement in their bodies.

The Trager method is a psychologically grounded physical approach to muscle relaxation, which is induced when a practitioner and patient achieve a state of mind called hook-up. Hook-up is described as a connection to a state of grace or a powerful and nourishing life force. It is the opposite of strain or effort.

Purpose

Psychophysical integration therapy has been helpful in relieving muscle discomfort in patients afflicted with **polio**, **muscular dystrophy**, Parkinson's disease, **multiple sclerosis**, post-stroke trauma, and psychiatric disturbances. The therapy is useful in alleviating such chronic conditions as back and leg **pain**. Athletes may benefit from this system to increase resilience to injuries and to improve their mental attitudes. In addition, the Trager Institute maintains that Tragerwork helps clients achieve greater mental clarity through the release of "deep-seated physical and mental patterns."

Description

Origins

Psychophysical integration therapy began with Dr. Milton Trager (1908–1997), who earned a medical degree in midlife after working out his approach to

KEY TERMS

Hook-up—A state of effortless connection with a life-enhancing force. Trager practitioners enter a state of hook-up before working with clients in order to focus on their needs. Trager himself described hook-up as a meditative process of "becoming one with the energy force that surrounds all living things."

Mentastics—The active phase of Trager therapy. Mentastics are a form of movement reeducation in which clients learn to reexperience movement as pleasurable and positive.

Tablework—The passive phase of Trager therapy, in which the practitioner uses gentle and noninvasive movements to allow the client to relax deeply and experience physical movement as free and effortless.

healing chronic pain. Trager was born with a spinal deformity and overcame it through practicing a variety of athletic exercises. At the time that he discovered his approach to bodywork, he was training to become a boxer. His therapy came to public attention when Esalen Institute in California, the famous center of the human potential movement, invited him to give a demonstration of his technique during the mid-1970s. Trager abandoned his private medical practice in 1977 to devote full energy to the development and further understanding of psychophysical integration. The Trager Institute, which continues his work, was founded in 1980.

The Trager method consists of two parts, a passive aspect referred to as tablework and an active aspect called Mentastics, which is a self-care **exercise** program. Although the benefits of the Trager approach are said to be cumulative, practitioners and clients appear to be free to set their own schedules for a series of sessions. There is no minimum number of sessions that clients must agree to take.

Tablework

The tablework is performed on a comfortable padded table. Sessions last about 60–90 minutes. The practitioner moves the client in ways that he or she naturally moves, in such a way that he or she experiences how it feels to move effortlessly and freely on one's own. The movements resemble general mobilization techniques, and incorporate some manual, cervical, and lumbar **traction**. The goal of tablework is to allow the client "slowly to give up muscular and mental control and sink into a very deep state of relaxation not unlike that experienced in hypnosis."

Mentastics

Mentastics are free-flowing dance-like movements intended to increase the client's self-awareness, as well as providing tools to help the client move through and control chronic pain. The client is encouraged to "let go," which means that he or she is asked to begin a movement, then release muscle tension and allow the weight of the body part involved to complete the motion. By experiencing movement as something pleasurable and positive rather than painful or negative, clients begin to loosen up, learn new movements more easily, and even begin inventing their own. In the early stages of treatment, clients are advised to do Mentastic movements at home for 10–15-minute sessions, three times per day.

Preparations

Prior to a session of tablework, the client dresses for comfort, "with a minimum of swimwear or briefs," according to the Trager Institute. The client is also covered with a drape. No oils or lotions are used.

The practitioner prepares for the session by clearing his or her mind of everything but the client, until he or she achieves a state of hook-up. This attitude of "relaxed meditative awareness" on the part of the practitioner is one of the unique features of Tragerwork. It is described as allowing the therapist "to connect deeply with the recipient in an unforced way and enables the practitioner to perceive the slightest responses from the [client's] body."

Precautions

Because of the unusual sensitivity and heightened awareness that is associated with the practitioner's touch, pain should never result from tablework sessions. It is important for clients to alert the practitioner to any pain associated with either the tablework or the Mentastics program.

Although the movements used in Trager tablework are gentle and noninvasive, clients who have had recent injuries or surgery should wait to heal before undertaking a course of Tragerwork.

Side effects

The Trager method should not produce physical side effects when employed by a qualified practitioner. It is possible that some clients may have emotional reactions associated with the release of physical patterns acquired as a response to trauma, but such reactions are unusual.

Research and general acceptance

Tragerwork, like other forms of bodywork, has gained increasing acceptance as a form of treatment since the 1980s. In 2000 there were 1,200 certified psychophysical integration practitioners in 15 countries worldwide. The therapy has been reported as a commonly employed treatment for mainstream athletes. In addition, the National Institutes of Health lists psychophysical therapy as a mind-body form of complementary alternative medicine.

Trans fatty acids

Definition

Trans fatty acids are unsaturated fatty acids with at least one double bond in the *trans* configuration. Unsaturated fatty acids are derived metabolically from saturated fatty acids by the abstraction of pairs of hydrogen atoms from adjacent methylene groups. The removal of a pair of hydrogen atoms gives rise to a double bond. The remaining hydrogen atoms can either be on the same side of the fatty acid molecule, in which case the double bond has the *cis* geometrical configuration, or on opposite sides giving the *trans* configuration. *Trans* fatty acids occur naturally in a small amounts in a few foods, however, the majority are formed during the partial hydrogenation of vegetable oils. This process converts vegetable oils into semi-solid fats for use in margarines, commercial cooking, and manufacturing processes. There is strong evidence that the consumption of *trans* fatty acids from industrial sources increases the risk of coronary heart disease (CHD).

Purpose

Whereas the presence of a *cis* bond in a fatty acid molecule affects the linearity of the fatty acid chain, making it fold back on itself, a *trans* bond has minimal effect on the conformation of the chain, making its physical properties more closely resemble those of a saturated fatty acid. The molecules of a *trans* fatty acid are able to pack together more closely than those of a *cis* isomer and this is reflected in differences in melting points. The melting point of the saturated fatty acid stearic acid (chain length of 18 carbons) is 157°F (69.6°C), the melting point of oleic acid (chain length of 18 carbons with one *cis* bond) is 55.8°F (13.2°C), whereas the melting point of eladic acid, the *trans* isomer of oleic acid, is 111°F (44.0°C). For this reason, partially hydrogenated vegetable oils are used extensively by the food industry, as their high *trans* fatty acid content gives the oils a longer shelf life and an increased stability during deep-frying. Their semi-solidity can be customized to enhance the palatability of baked goods and sweets.

Description

Sources and consumption of trans fatty acids in the United States diet

The average consumption of industrially produced *trans* fatty acids in the United States is between 2 to 3% of total calories consumed. The major sources of *trans* fatty acids in the American diet are deep-fried foods, bakery products, packaged snack foods, margarines, and crackers. Naturally occurring *trans* fatty acids are found in meats and dairy products from cows, sheep, and other ruminant animals; they are produced in the forestomach of the animal where polyunsaturated fatty acids of plant origin, such as linoleic acid and linolenic acid, can undergo partial or complete hydrogenation by the action of symbiotic anaerobic bacteria present in the ruminant stomach. These naturally occurring *trans* fatty acids are consumed in much smaller amounts, approximately 0.5% of total energy intake.

Trans fatty acids from ruminant sources

The predominant *trans* isomer in ruminant animals is vaccenic acid, from which conjugated linolenic acid (CLA) can be formed. It is possible to change the *trans* fatty acid content of ruminant products by altering the animals' feed although levels of *trans* fatty acids in meat and milk are already relatively low, between 1 and 8% of total fat content. With respect to CLA, it is considered desirable to increase levels in foods rather than to decrease levels. This is due to the suggested health benefits of CLA in humans, such as reduced insulin sensitivity and improved immune function, although the evidence remains inconclusive.

There is no association between intake of *trans* fatty acids from ruminant sources and risk of CHD and in fact some studies have shown non-significant trends towards

an inverse association. The absence of an positive association of *trans* fatty acids from ruminant sources compared with from industrial sources may be due to lower levels of intake (less than 0.5% of total energy intake), different biological effects of different isomers, or the presence of other factors in meat and diary products that outweigh any effects of the small amount of *trans* fatty acids they contain. Further research in these areas is needed although it would seem that *trans* fatty acids from ruminant sources do not pose a threat to public health.

Precautions

The physiological effects of trans fatty acids from industrial sources

The main effects of *trans* fatty acids are on serum lipid levels. Numerous controlled dietary trials have been conducted to evaluate the effect of isocaloric replacement of saturated or *cis* unsaturated fatty acids with *trans* fatty acids. The data from many of these studies has been used in a number of large meta-analyses, all of which strongly indicate that compared with saturated or *cis* unsaturated fatty acids, the consumption of *trans* fatty acids raises levels of low density lipoprotein (LDL) cholesterol, reduces levels of high density lipoprotein (HDL) cholesterol and increases the ratio of total cholesterol to HDL cholesterol, all of which are powerful risk factors from CHD.

There is substantial evidence to show that *trans* fatty acids also promote systemic inflammation. In a large trial of women, greater intake of *trans* fatty acids was associated with increased activity of the tumour necrosis factor (TFN) system, a biomarker used to measure inflammation. Among those with a higher body mass index (BMI), a greater intake of *trans* fatty acids was also associated with other inflammatory substances. The presence of inflammation is an independent risk factor for **atherosclerosis**, sudden **death** from cardiac causes, **diabetes mellitus**, and **heart failure**. Thus the inflammatory effects of *trans* fatty acids contribute further to overall CHD risk.

The risk to health of consuming *trans* fatty acids from industrial sources has been recognized and acknowledged by the United States government. The Food and Drug Administration (FDA) made it compulsory from 2006, for **nutrition** labels for all conventional foods and supplements to indicate the content of *trans* fatty acids. In addition, the Department of Agriculture has made a limited intake of *trans* fatty acids a key recommendation of the new food pyramid guidelines, following the recommendations of the Dietary Guidelines Advisory Committee that intake of *trans* fatty acids should be less than 1% of total energy. Furthermore, action is being taken at local levels; the New York City Department of Health and Mental Hygiene has asked 20,000 restaurants and 14,000 food suppliers to eliminate partially hydrogenated oils from kitchens and to provide foods free from industrially produced *trans* fatty acids. Although the elimination of these *trans* fatty acids may be challenging, experience in other countries, such as Denmark, indicates that these fats can largely be replaced by *cis* unsaturated fats without increasing the cost or availability of foods.

Health care providers should advise consumers about how to minimize the intake of *trans* fatty acids, consumers should be able to recognize and avoid products containing *trans* fatty acids and restaurants and food manufacturers should use alternative fats in food production and preparation. These measures should ensure a reduction in *trans* fatty acid consumption and result in substantial health benefits particularly a reduction in the incidence of CHD.

Complications

Trans fatty acid intake and risk of disease

***TRANS* FATTY ACID INTAKE AND CHD.** On a per calorie basis, *trans* fatty acids increase the risk of CHD more than any other macronutrient, conferring a substantially increased risk even at low levels of consumption (between 1 to 3% of total energy intake). Even a small rise in energy intake from *trans* fatty acids can cause a large increase risk. A meta-analysis of four prospective cohort studies that included data from 140,000 subjects showed a 23% increase in CHD incidence when energy intake from *trans* fatty acids increased by just 2%. So dramatic is the impact of *trans* fatty acids on CHD risk, another study showed that the positive association between levels of *trans* fatty acids in adipose tissue (a biomarker for dietary intake) and CHD risk was diminished after 1996, when *trans* fatty acids where eliminated from margarines sold in Australia and the population's consumption levels decreased.

The potential benefits of reducing of reducing consumption of *trans* fatty acids from industrial sources on the incidence of CHD in the United States has been calculated. On the basis of predicted changes in total and HDL cholesterol, CHD events could be reduced by between 3 and 6 percent. If the influence of *trans* fatty acids on other risk factors such as inflammatory effects is considered, CHD events could be reduced by 10–19% (equivalent to between 72,000 and 228,000 CHD events each year). This reduction could be even greater, if healthier *cis* unsaturated fatty acids, including **omega-3 fatty acids**, are used to replace *trans* fatty acids.

***TRANS* FATTY ACID INTAKE AND DIABETES.** The association between risk of diabetes and *trans* fatty acid intake is less clear. Three prospective studies have investigated this relationship and in two of the studies, consumption of *trans* fatty acids was not significantly associated with increased risk of diabetes. However, in a study of nearly 85,000 female nurses a strong positive association was found. The nurses were followed for 16 years, information of dietary intake was periodically updated and self-reported diabetes was validated. The conclusions of no association in the first two studies may be explained by the relatively low intake in one cohort of male health professionals (average intake of 1.3% energy).

Parental concerns

Parents should eliminate all sources of *trans* fatty acids from industrial sources from their children's **diets** as these have no intrinsic health value above their energy value. Therefore their consumption is linked with considerable potential harm and no apparent benefit. As adverse effects are seen at even low levels of intake, between 1 and 3% of total energy (2–7g per day for a person consuming 2,000 calories), it seems complete or near complete avoidance of *trans* fatty acids should be advised in order to minimize health risks.

Transcranial Doppler ultrasonography

Definition

Transcranial **Doppler ultrasonography** is a noninvasive method of analyzing blood flow in the brain.

Purpose

The blood that flows through the brain distributes nutrients to the brain and removes wastes. This flow maintains the high rate of metabolism necessary for the brain to function. Restrictions in blood flow may occur from vessel narrowing (stenosis), clot formation (thrombosis), blockage (**embolism**), or blood vessel rupture (hemorrhage). Lack of sufficient blood flow (**ischemia**) threatens brain tissue and may cause a **stroke**.

The flow of blood through the arteries in the brain can be analyzed using transcranial Doppler ultrasonography (TCD). TCD is a form of ultrasound, in which high frequency sound waves bounce off or pass through body tissues. While most other types of ultrasonography create images of the tissue being studied, the results of TCD are audible sounds that the examiner listens to and records.

Doppler ultrasonography uses what is called the Doppler effect to measure the rate and direction of blood flow in the vessels. Just as a siren's pitch sounds higher when its source is moving toward you and lower as it moves away, so too will ultrasound waves change pitch, or frequency, as they bounce off the red blood cells moving in the blood. It is these pitch changes that produce the audible sounds during the exam.

Changes in frequency can be used to measure both the direction and the speed of blood flow. Faster blood flow causes a greater change in frequency. Combined with other tests, this information can be used to locate restrictions in the blood vessels in the brain, and to track changes in blood flow over time. In this way, TCD gives valuable information about the site of a stroke and the patient's progress after a stroke. TCD is also used to evaluate the contraction of blood vessels that can occur if a blood vessel ruptures.

Precautions

Ultrasonography procedures are safe, noninvasive, and painless. No special precautions are necessary.

Description

TCD is done with either one or two probes placed against the skin. The examiner spreads a clear gel on the areas of the head where the probe will be placed. Usually, the probes are placed on the temple, on the base of the skull at the back of the neck, and over the closed eyelid. In these places, there is the least amount of thick protective bone and the sound waves can penetrate the best. The examiner adjusts the probe position and orientation to direct the sound waves toward the blood vessels of interest. Finding the best approach may take some time. A compression test may be performed during the exam. In this test, the main artery in the neck (carotid artery) is briefly compressed, and changes in blood flow patterns are observed. A full TCD exam may last 30–45 minutes, and often longer in patients with disease.

Preparation

No special preparation is needed. The patient should remove **contact lenses**, and may wish to avoid the use of eye makeup, since the gel is likely to smear it.

Aftercare

The gel is washed off with soap and water. No other after care is needed.

Risks

TCD is noninvasive and has no risks. A compression test is occasionally, though very rarely, hazardous for a patient with narrowed arteries (**atherosclerosis**), since the increased pressure may dislodge a piece of the substance that causes the narrowing (plaque).

Normal results

TCD produces an audible sound that varies with the heartbeat. It also varies depending on the direction and rate of flow through the vessel being examined. Each of the vessels in the brain has a characteristic direction of flow, which can be detected by TCD. Flow rates are somewhat variable from person to person.

Abnormal results

Lack of flow indicates a vessel has been completely blocked (although absence of a signal may also be due to absorption of sound waves by bone). If blood flows in the wrong direction or alternates between normal and reverse flow, it may mean there is a blockage elsewhere. This happens because blood is rerouted due to abnormalities in pressure caused by the blockage.

If the speed of flow is increased, it may mean that blood is flowing through a restricted area that is just "upstream" from the probe. Intuitively, one might think that a restricted blood vessel would cause the speed of blood flow to slow down. However, the opposite is true. This is because the same amount of blood going through a narrower opening must go faster. Increased speed is also seen if a vessel is carrying rerouted blood.

Transesophageal echocardiography

Definition

Transesophageal **echocardiography** is a diagnostic test using an ultrasound device that is passed into the esophagus of the patient to create a clear image of the heart muscle and other parts of the heart. A tube with a device called a transducer is passed down into the patient's throat and into the esophagus (the food tube that connects the mouth to the stomach). The transducer directs ultrasound waves into the heart, and the reflected sound waves picked up by the transducer are translated into an image of the heart.

Purpose

Since the esophagus is right next to the heart, transesophageal echocardiography provides a very clear picture of the heart. It can provide information on the size of the heart, its pumping strength, and the location and extent of any damage to its tissues. It can detect abnormal tissue growth around the heart valves. It is also good at detecting abnormalities in the pattern of blood flow, such as the backward flow of blood through partly closed heart valves, known as regurgitation or insufficiency. It is especially useful in cases in which conventional echocardiography (a test where the transducer is kept on the patient's chest) cannot offer a good image, such as when the patient is obese or has a thick chest wall. It is useful for monitoring heart function during cardiac surgery and detecting **blood clots** in the left atrium of the heart.

Precautions

Patients should avoid consuming alcohol for a day or so before the procedure, since alcohol may amplify the effects of the sedative used with the procedure.

Description

Echocardiography creates an image of the heart using ultra-high-frequency sound waves–sound waves that are much too high in frequency to be heard by the human ear. The technique is very similar to ultrasound scanning commonly used to visualize the fetus during **pregnancy**.

A transesophageal echocardiography examination generally lasts 30–60 minutes. The patient is given a mild sedative and the back of the throat is sprayed with a local anesthetic, in order to suppress the gag reflex. Next, a special viewing tube called an endoscope, containing a tiny transducer, is passed through the mouth and into the esophagus. It is carefully moved until it is positioned directly next to the heart. Essentially a modified microphone, the transducer directs ultrasound waves into the heart, some of which get reflected (or "echoed") back to the transducer. Different tissues and blood all reflect ultrasound waves differently. These sound waves can be translated into a meaningful image of the heart, which is displayed on a monitor or recorded on paper or tape. The transducer may be moved several times during the test to help doctors get a better view of the heart.

KEY TERMS

Endoscope—An instrument used to see and examine the inside of a body cavity or organ.

Gag reflex—A normal reflex consisting of elevation of the palate, retraction of the tongue, and contraction of the throat muscles.

Regurgitation—Backward flow of blood through a partly closed valve.

Transducer—A device that converts electrical signals into ultrasound waves and ultrasound waves back into electrical impulses.

Ultrasound—Sound waves at a frequency of 20,000 kHz, often used for diagnostic imaging.

Preparation

The patient may be given a mild sedative before the procedure, and an anesthetic is sprayed into the back of the throat in order to suppress the gag reflex.

Aftercare

After the test, it is important to refrain from eating or drinking until the gag reflex has returned–otherwise, the patient may accidentally inhale some of the food or beverage. If a sedative has been given, patients should not drive or operate heavy machinery for at least 10-12 hours. They should avoid consuming alcohol for a day or so, since alcohol may amplify the effect of the sedative.

Risks

Transesophageal echocardiography may cause gagging and discomfort when the transducer is passed down into the throat. Patients may also experience **sore throat** for a few days after the test. In rare cases, the procedure may cause bleeding or perforation of the esophagus or an inflammatory condition known as infective **endocarditis**. The patient may have an adverse reaction to the sedative or local anesthetic.

Normal results

A normal transesophageal echocardiogram shows a normal heart structure and the normal flow of blood through the heart chambers and heart valves.

Abnormal results

A transesophageal echocardiogram may show a number of abnormalities in the structure and function of the heart, such as thickening of the wall of the heart muscle (especially the left ventricle). Other abnormalities can include blood leaking backward through the heart valves (regurgitation), or blood clots in the left atrium of the heart.

Robert Scott Dinsmoor

Transferrin test *see* **Iron tests**

Transfusion

Definition

Transfusion is the process of transferring whole blood or blood components from a donor to a recipient.

Purpose

Transfusions are given to restore lost blood, to improve clotting time, and to improve the ability of the blood to deliver oxygen to the body's tissues. About 32,000 pints of donated blood are transfused each day in the United States.

In the United States, blood collection is strictly regulated by the Food and Drug Administration (FDA), which has rules for the collection, processing, storage, and transportation of blood and blood products. In addition, the American Red Cross, the American Association of Blood Banks (AABB), and most states have specific rules for the collection and processing of blood. The main purpose of regulation is to ensure the quality of transfused blood and to prevent the transmission of infectious diseases through donated blood. Before blood and blood products are used, they are extensively tested for such infectious agents as hepatitis and human **immunodeficiency** virus (HIV).

Blood and its components

Either whole blood or its components can be used for transfusion. Most blood collected from donors is broken down (fractionated) into components that are used to treat specific problems or diseases. Treating patients with fractionated blood is the most efficient way to use the blood supply.

WHOLE BLOOD. Whole blood is used exactly as received from the donor. Blood components are parts of whole blood, such as red blood cells (RBCs), white blood cells (WBCs), plasma, platelets, clotting factors, and immunoglobulins. Whole blood is used only when needed or when fractionated components are not available, because too much whole blood can raise the recipient's blood pressure. Use of blood components is a more efficient way to use the blood supply, because blood that has been fractionated can be used to treat more than one person.

Whole blood is generally used when a person has lost a large amount of blood. Such blood loss can be caused by injury or surgical procedures. Whole blood is given to help restore the blood volume, which is essential for maintaining blood pressure. It is also given to ensure that the body's tissues are receiving enough oxygen. Whole blood is occasionally given when a required blood fraction is unavailable in isolated form.

RED BLOOD CELLS. Red blood cells (RBCs) carry oxygen throughout the body. They pick up oxygen as they pass through the lungs, and give up oxygen to the other tissues of the body as they are pumped through the arteries and veins. When patients do not have enough RBCs to properly oxygenate their bodies, they can be given a transfusion with RBCs obtained from donors. This type of transfusion will increase the amount of oxygen carried to the tissues of the body. RBCs are recovered from whole blood after donation. They are then typed, removed from the watery blood plasma to minimize their volume (packed), and stored. RBCs are given to people with anemia (including **thalassemia**), whose bone marrow does not make enough RBCs, or who have other conditions that decrease the number of RBCs in the blood. Occasionally, red blood cells from rare blood types are frozen. Once frozen, RBCs can survive for as long as 10 years. Packed RBCs are given in the same manner as whole blood.

WHITE BLOOD CELLS. White blood cells (WBCs) are another infection-fighting blood component. On rare occasions, white blood cells are given by transfusion to

KEY TERMS

ABO blood groups—A system in which human blood is classified according to the A and B antigens found in red blood cells. Type A blood has the A antigen, type B has the B antigen, AB has both, and O has neither.

Antibody—A simple protein produced by the body to destroy bacteria, viruses, or other foreign bodies. The production of each antibody is triggered by a specific antigen.

Antigen—A substance that stimulates the immune system to manufacture antibodies (immunoglobulins). The function of antibodies is to fight off such intruder cells as bacteria or viruses. Antigens stimulate the blood to fight other blood cells that have the wrong antigens. If a person with blood type A is given a transfusion with blood type B, the A antigens will fight the foreign blood cells as though they were an infectious agent.

Apheresis—A procedure in which whole blood is withdrawn from a donor, a specific blood component is separated and collected, and the remainder is reinfused into the patient.

Autologous blood—The patient's own blood, drawn and set aside before surgery for use during surgery in case a transfusion is needed.

Fractionation—The process of separating the various components of whole blood.

Hemoglobin—The red pigment in red blood cells that transports oxygen.

Hemolysis—The destruction of red blood cells through disruption of the cell membrane, resulting in the release of hemoglobin. A hemolytic transfusion reaction is one that results in the destruction of red blood cells.

Immunoglobulin—An antibody.

Infusion—Introduction of a substance directly into a vein or tissue by gravity flow.

Injection—Forcing a fluid into the body by means of a needle and syringe.

Plasma—The liquid portion of blood, as distinguished from blood cells. Plasma constitutes about 55% of blood volume.

Platelets—Disk-shaped structures found in blood that play an active role in blood clotting. Platelets are also known as thrombocytes.

Rh (rhesus) factor—An antigen present in the red blood cells of 85% of humans. A person with Rh factor is Rh positive (Rh+); a person without it is Rh negative (Rh-). The Rh factor was first identified in the blood of a rhesus monkey.

Serum (plural, sera)—The clear fluid that separates from blood when the blood is allowed to clot completely. Blood serum can also be defined as blood plasma from which fibrinogen has been removed.

treat life-threatening infections. Such transfusions are given when the WBC count is very low or when the patient's WBCs are not functioning normally. Most of the time, however, **antibiotics** are used in these cases.

PLASMA. Plasma is the clear yellowish liquid portion of blood. It contains many useful proteins, especially clotting factors and immunoglobulins. After plasma or plasma factors are processed, they are usually frozen. Some plasma fractions are freeze-dried. These fractions include clotting factors I through XIII. Some people have an inherited disorder in which the body produces too little of the clotting factors VIII (**hemophilia** A) or IX (hemophilia B). Transfusions of these clotting factors help to stop bleeding in people with hemophilia. Frozen plasma must be thawed before it is used; freeze-dried plasma must be mixed with liquid (reconstituted). In both cases, these blood fractions are usually small in volume and can be injected with a syringe and needle.

PLATELETS. Platelets are small disk-shaped structures in the blood that are essential for clotting. People who do not have enough platelets (a condition called **thrombocytopenia**) have bleeding problems. People who have lymphoma or leukemia and people who are receiving **cancer** therapy do not make enough platelets. Platelets have a very short shelf life; they must be used within five days of **blood donation**. After a unit of blood has been donated and processed, the platelets in it are packed into bags. A platelet transfusion is given in the same manner as whole blood.

IMMUNOGLOBULINS. Immunoglobulins are the infection-fighting fractions in blood plasma. They are also known as **gamma globulin**, antibodies, and immune sera. Immunoglobulins are given to people who have difficulty fighting infections, especially people whose immune systems have been depressed by such diseases as **AIDS**. Immunoglobulins are also used to prevent **tetanus** after a cut has been contaminated; to treat animal **bites** when **rabies** is suspected; or to treat severe childhood diseases. Generally, the

volume of immunoglobulins used is small, and it can be injected.

Demographics

In order to donate blood, an individual must be at least 17 years old, weigh at least 110 lb (50 kg), and be in generally good health. The average blood donor is a white, married, college-educated male between the ages of 30 and 50. Twenty-five percent of people receiving blood transfusions are over the age of 65, although the elderly constitute only 13% of the population. Fewer than 5% of Americans donate blood each year.

Description

Blood is collected from the donor by inserting a large needle into a vein in the arm, usually one of the larger veins near the inside of the elbow. A tourniquet is placed on the upper arm to increase the pressure in the arm veins, which makes the veins swell and become more accessible. Once the nurse or technician has identified a suitable vein, she or he sterilizes the area where the needle will be inserted by scrubbing the skin with a soap solution or an antiseptic that contains iodine. Sometimes both solutions are used. The donor lies on a bed or cot during the procedure, which usually takes between 10 and 20 minutes. Generally, an 18-gauge needle is used. This size of needle fits easily into the veins and yet is large enough to allow blood to flow easily. Human blood will sometimes clot in a smaller needle and stop flowing. The donor's blood is collected in a sterile plastic bag that holds one pint (450 mL). The bags contain an anticoagulant to prevent clotting and preservatives to keep the blood cells alive. A sample of the donator's blood is collected at the time of donation and tested for infectious diseases. The blood is not used until the test results confirm that it is safe. Properly handled and refrigerated, whole blood can last for 42 days.

The recipient of a transfusion is prepared in much the same way as the blood donor. The site for the needle insertion is carefully washed with a soap-based solution followed by an antiseptic containing iodine. The skin is then dried and the transfusion needle inserted into the vein. During the early stages of a transfusion, the recipient is monitored closely to detect any adverse reactions. If no signs of adverse reaction are evident, the patient is monitored occasionally for the duration of the transfusion period. Upon completion of the transfusion, a compress is placed over the needle insertion site to prevent extensive bleeding.

Blood typing

All donated blood is typed, which means that it is analyzed to determine which of several major and minor blood types (also called blood groups) it belongs to. Blood types are genetically determined. The major types are classified by the ABO system. This system groups blood with reference to two substances in the red blood cells called antigen A and antigen B. The four ABO blood types are A, B, AB, and O. Type A blood has the A antigen, type B has the B antigen, type AB has both, and type O has neither. These four types of blood are further classified by the Rh factor. The Rh, or rhesus factor, is also an antigen in the red blood cells. A person who has the Rh factor is Rh positive; a person who does not have the factor is Rh negative. If a person has red blood cells with both the B and the Rh antigens, that person is said to have a B positive (B+) blood type. Blood types determine which kinds of donated blood a patient can receive. Generally, patients are limited to receiving only blood of the exact same ABO and Rh type as their own. For example, a person with B+ blood can receive blood or blood cells only from another person with B+ blood. An exception is blood type O. Individuals with type O blood are called universal donors, because people of all blood types can accept their blood.

Blood can also be typed with reference to several other minor antigens, such as Kell, Kidd, Duffy, and Lewis. These minor antigens can become important when a patient has received many transfusions. These patients tend to build up an immune response to the minor blood groups that do not match their own. They may have an adverse reaction upon receiving a transfusion with a mismatched minor blood group. A third group of antigens that may cause a reaction are residues from the donor's plasma attached to the RBCs. To eliminate this problem, the RBCs are rinsed to remove plasma residues. These rinsed cells are called washed RBCs.

Other transfusion procedures

Autologous transfusion is a procedure in which patients donate blood for their own use. Patients who are to undergo surgical procedures requiring a blood transfusion may choose to donate several units of blood ahead of time. The blood is stored at the hospital for the patient's exclusive use. Autologous donation assures that the blood type is an exact match. It also assures that no infection will be transmitted through the blood transfusion. Autologous donation accounts for 5% of blood use in the United States each year.

Directed donors are family or friends of the patient who needs a transfusion. Some people think that family and friends provide a safer source of blood than the general blood supply. Studies do not show that directed donor blood is any safer. Blood that is not used for the identified patient becomes part of the general blood supply.

Apheresis is a special procedure in which only certain specific components of a donor's blood are collected. The remaining blood fractions are returned to the donor. A special blood-processing instrument is used in apheresis. It fractionates the blood, saves the desired component, and pumps all the other components back into the donor. Because donors give only part of their blood, they can donate more frequently. For example, people can give almost 10 times as many platelets by apheresis as they could give by donating whole blood. The donation process takes about one to two hours.

Preparation

The first step in blood donation is the taking of the donor's medical history. Blood donors are questioned about their general health, their lifestyle, and any medical conditions that might disqualify them. These conditions include hepatitis, AIDS, cancer, heart disease, **asthma**, **malaria**, bleeding disorders, and high blood pressure. Screening prevents people from donating who might transmit diseases or whose medical condition would place them at risk if they donated blood. Some geographical areas or communities have a high rate of hepatitis or AIDS. Blood collection in most of these areas has been discontinued indefinitely.

The blood pressure, temperature, and pulse of donors are taken to ensure that they are physically able to donate blood. One pint (450 mL) of blood is usually withdrawn, although it is possible to donate smaller amounts. The average adult male has 10–12 pints of blood in his body; the average adult female has 8–9 pints in hers. Within hours after donating, most people's bodies have replaced the fluid lost with the donated blood, which brings their blood volume back to normal. Replacement of the blood cells and platelets, however, can take several weeks. Pregnant women and people with low blood pressure or anemia should not donate blood or should limit the amount of blood they give. Generally, people are allowed to donate blood only once every two months. This restriction ensures the health of the donor and discourages people from selling their blood. The former practice of paying donors for blood has essentially stopped. Donors who sell blood tend to be at high risk for the transmission of blood-borne diseases.

Aftercare

Recipients of blood transfusion are monitored during and after the transfusion for signs of an adverse reaction. Blood donors are generally given fluids and light refreshments to prevent such possible side effects as **dizziness** and **nausea**. They are also asked to remain in the donation area for 15–20 minutes after giving blood to make sure that they are not likely to faint when they leave.

Risks

Risks for donors

For donors, the process of giving blood is very safe. Only sterile equipment is used and there is no chance of catching an infection from the equipment. There is a slight chance of infection at the puncture site if the skin is not properly washed before the collection needle is inserted. Some donors feel lightheaded when they sit up or stand for the first time after donating. Occasionally, a donor will faint. Donors are encouraged to drink plenty of liquids to replace the fluid lost with the donated blood. It is important to maintain the fluid volume of the blood so that the blood pressure will remain stable. Strenuous **exercise** should be avoided for the rest of the day. It is normal to feel some soreness or to find a small bluish bruise at the site of the needle insertion. Most donors have very slight symptoms or no symptoms at all after giving blood.

Risks for recipients

A number of precautions must be taken for transfusion recipients. Donated blood must be matched with the recipient's blood type, as incompatible blood types can cause a serious adverse reaction (transfusion reaction). Blood is introduced slowly by gravity flow directly into the veins (intravenous infusion) so that medical personnel can observe the patient for signs of adverse reactions. People who have received many transfusions may develop an immune response to some factors in foreign blood cells. This immune reaction must be evaluated before the patient is given new blood.

Adverse reactions to mismatched blood (transfusion reaction) is a major risk of blood transfusion. Transfusion reaction occurs when antibodies in the recipient's blood react to foreign blood cells introduced by the transfusion. The antibodies bind to the foreign cells and destroy them. This destruction is called a hemolytic reaction. In addition, a transfusion reaction may also cause a hypersensitivity of the immune system that may in turn

result in tissue damage within the patient's body. The patient may also have an allergic reaction to mismatched blood.

The first symptoms of transfusion reaction are a feeling of general discomfort and **anxiety**. Breathing difficulties, flushing, and a sense of pressure in the chest or back **pain** may also be present. Evidence of a hemolytic reaction can be seen in the urine, which will be colored from the hemoglobin leaking from the destroyed red blood cells. Severe hemolytic reactions are occasionally fatal. Reactions to mismatches of minor factors are milder. These symptoms include itchiness, dizziness, **fever**, **headache**, rash, and swelling. Sometimes the patient will experience breathing difficulties and **muscle spasms**. Most adverse reactions from mismatched blood are not life-threatening.

Infectious diseases can also be transmitted through donated blood and constitute another major risk of blood transfusion. The infectious diseases most often acquired from blood transfusion in the United States are hepatitis and HIV.

Patients who are given too much blood can develop high blood pressure, a concern for people who have heart disease. Very rarely, an air **embolism** is created when air is introduced into a patient's veins through the tubing used for intravenous infusion. The danger of embolism is greatest when infusion is begun or ended. Care must be taken to ensure that all air is bled out of the tubing before infusion begins, and that the infusion is stopped before air can enter the patient's blood system.

Normal results

Most individuals will feel only a slight sting from the needle used during the blood donation process, and will not experience any side effects after the procedure is over. Plasma is regenerated by the body within 24 hours, and red blood cells within a few weeks. Patients who receive a blood transfusion will usually experience mild or no side effects.

Morbidity and mortality rates

The risk of acquiring an **infectious disease** from a blood transfusion is very low. The risk of HIV transmission is one in 2,135,000 units of blood; **hepatitis B** virus (HBV), one in 205,000 units; and **hepatitis C** virus (HCV), one in 1,935,000 units. Bacterial contamination (a cause of infection) is identified in one in 500,000 for red blood cell units and one in 15,400 for apheresis platelet units. In about 1 in 600,000 to 800,000 transfusions a "fatal misidentification error" occurs; and in about 1 in 12,000 to 19,000 cases a non-fatal error occurs.

Alternatives

There are several alternatives to blood transfusion. These include:

- Volume expanders. Certain fluids (saline, Ringer's lactate solution, dextran, etc.) may be used to increase the patient's blood volume without adding additional blood cells.
- Blood substitutes. Much research is currently being done into compounds that can replace some or all of the functions of blood components. One such compound, called HBOC-201 or Hemopure, is hemoglobin derived from bovine (cow) blood. Hemopure shows promise as a substitute for red blood cell transfusion.
- Bloodless surgery. It may be possible to avoid excessive blood loss through careful planning prior to surgery. Specialized instruments can minimize the amount of blood lost during a procedure. It is also possible to collect some of the blood lost during surgery and reinfuse it into the patient at the end of the operation.

Transhepatic biliary catheterization

Definition

Transhepatic biliary catheterization is a surgical procedure during which a catheter is inserted into the bile duct to relieve an obstruction.

Purpose

Bile is a fluid made in the liver and stored in the gall bladder. The function of bile is to break down fats during digestion. When fatty foods move into the intestine, bile is released from the gall bladder, travels through the bile duct, and enters the first part of the small intestine (duodenum).

If the bile duct is blocked, the skin becomes yellowish (jaundiced), the abdomen is painful, and a **fever** develops. The bile duct can be blocked by **gallstones**, surgical injury, infection in the duct, or by tissue growth due to **cancer**. Transhepatic biliary catheterization is performed to relieve bile duct blockage. The most common reason for this procedure is to relieve obstruction from the overgrowth of cancer cells. Obstruction due to gallstones is usually cleared by other means.

Precautions

Transhepatic biliary catheterization is done when cancer has progressed to the point where all the malignant cells cannot be removed by surgery. Patients who need transhepatic biliary catheterization often suffer from additional complications of their cancer. Because of the likelihood of bleeding from the liver, this procedure should not be done on patients who have blood clotting abnormalities.

Description

Transhepatic biliary catheterization is performed by inserting a needle through the skin, into the abdomen, through the liver, and into the bile duct. A wire attached to the needle then guides the catheter into place. The procedure can take several hours. The patient is given medication for **pain**.

The catheter can either reestablish bile flow into the duodenum or reroute the bile so it drains into a bag outside the body. The choice depends on the extent and position of the obstruction.

Preparation

The standard preoperative blood tests are performed. The patient should not eat or drink the day of the procedure.

Aftercare

The patient must stay in bed after the procedure for at least six hours, to reduce the risk of bleeding. A nurse checks vital signs and looks for indications of complication such as pain, cramping, or leakage around the catheter. The catheter is flushed periodically to keep it open. Patient and caregiver education on how to keep the catheter clean and irrigated is an important part of aftercare.

Risks

The most common complication of transhepatic biliary catheterization is bleeding as a result of puncturing the liver. Infection may also result from this procedure. Sometimes the catheter itself becomes blocked and is ineffective.

Normal results

Transhepatic biliary catheterization is a treatment, not a cure. Successful treatment relieves the blocked bile duct, but does not change the underlying conditions that caused the blockage.

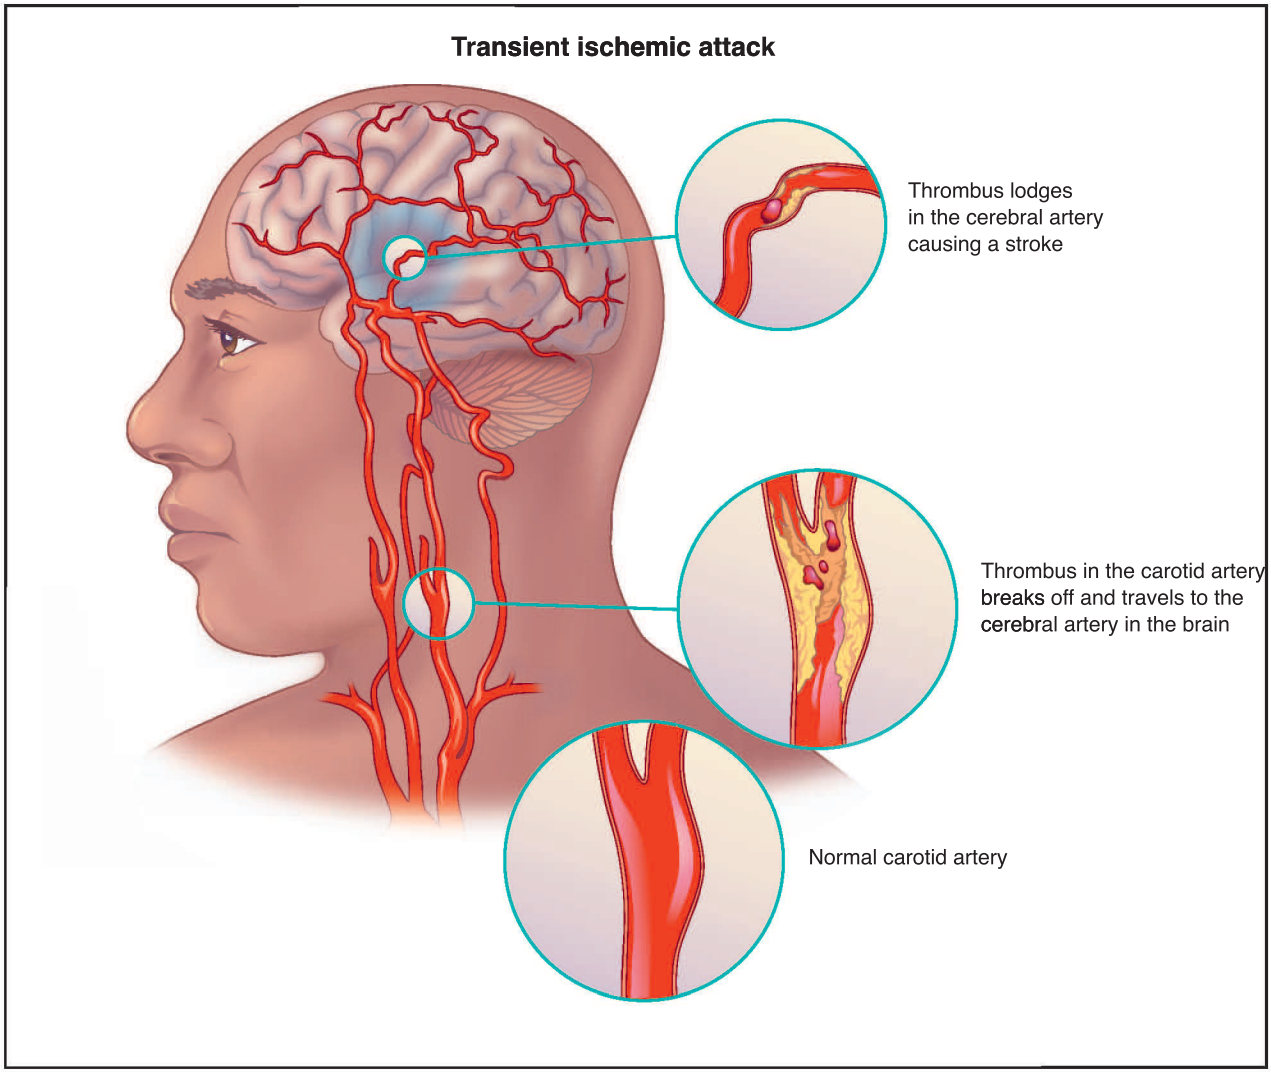
Transient ischemic attack

Definition

A transient ischemic attack, or TIA, is often described as a mini-stroke. Unlike a **stroke**, however, the symptoms can disappear within a few minutes. TIAs and strokes are both caused by a disruption of the blood flow to the brain. In TIAs and most strokes, this disruption is caused by a blood clot blocking one of the blood vessels leading to the brain. The blockage produces symptoms such as sudden weakness or **numbness** on one side of the body, sudden dimming or loss of vision, and difficulty speaking or understanding speech. If the symptoms are caused by a TIA, they last less than 24 hours and do not cause brain damage. Stroke-associated symptoms, on the other hand, do not go away and may cause brain damage or **death**. TIAs can serve as an early warning sign of stroke and require immediate medical attention.

Demographics

About 240,000 people in the United States are diagnosed with a TIA each year. However, this number may be low, since symptoms are transient and not everyone experiencing them will see a doctor. The risk of a TIA increases with age from about 2 per 10,000 people under age 35 to 1,500 people per 10,000 over age 85. Of people who have a TIA, roughly one-third will never have another, while the others will go on to have



In a transient ischemic attack (TIA), blood clots inhibit blood flow to the brain, causing symptoms similar to a stroke. *(Illustration by Electronic Illustrators Group. Reproduced by permission of Gale, a part of Cengage Learning.)*

additional TIAs or a stroke. About 15% of people who have a stroke had a previous TIA.

Description

Strokes are the third leading cause of death in the United States and the leading cause of disability. Approximately 795,000 Americans have strokes annually; 20% die within one year. About 85% of these strokes are classified as ischemic. In ischemic stroke, a blood vessel leading to the brain becomes blocked and an area of the brain is deprived of oxygenated blood. (The other 15% of strokes are caused by bleeding from a blood vessel that has ruptured.) Without the blood supply, the cells in that area of the brain die. Since brain cells cannot grow back, the functions that are controlled by that brain area may be permanently lost.

Approximately 15% of strokes are preceded by one or more TIAs. However, an estimated one-third of all TIAs are followed by a stroke within five years. They are considered a medical emergency and prompt medical attention is very important.

Risk factors for strokes and TIAs are very similar. The risk of a TIA or stroke is higher among men, African Americans, people over age 65, and people with heart disease or diabetes. Smokers, people with high blood pressure, and people who are overweight also have a greater risk for TIAs and strokes.

Causes and symptoms

A TIA is caused by a temporary blockage of one of the arteries that leads into the brain. Small **blood clots**, called microemboli, are the immediate cause of the blockage. The blockage forms because of damage or disease within the circulatory system. Blood clots can form in blood vessels because of artery damage, vascular disease, and other cardiovascular problems. For example, **atherosclerosis** is strongly associated with TIAs. Atherosclerosis is the build-up of fatty deposits or plaque at certain areas in the circulatory system. Clotting cells in blood, called platelets, tend to stick to atherosclerotic plaques or other damaged sites within blood vessels. Occasionally, a clot may grow large enough to block a blood vessel, or a piece of a clot may break off and circulate to other areas of the body. If a clot does not dissolve quickly enough, it can lodge in a blood vessel and block it. In TIAs, the microemboli dissolve within a short time.

Blood flows into the brain through two main pathways: the carotid arteries and the vertebrobasilar arteries. The carotid arteries are located on the front of the neck; the vertebrobasilar arteries are at the base of the skull at the back of the head. The symptoms produced by a TIA are determined by the arteries affected.

If a vertebrobasilar artery is blocked, common symptoms include double vision and **dizziness**, **nausea and vomiting**, difficulty speaking, and problems understanding and using spoken words. There may also be numbness around the mouth and a **tingling** sensation in the limbs. Blockage of a carotid artery produces complete loss of vision, dimmed or foggy vision, and **paralysis** or weakness on one side of the body. These symptoms also may be accompanied by language problems and speech difficulty. With either type of blockage, the microemboli dissolve within hours and full function returns.

Diagnosis

Examination

The goal of diagnosis is to identify the precise cause of the TIA and to recommend treatment. Initial information that an individual can supply includes a medical history, what drugs are currently being taken and why, and a full description of the symptoms. Blood tests are ordered to screen blood counts—the numbers of specific blood cell types—and to measure glucose (sugar) and lipid (fats, including cholesterol) levels. Based on this information and a **physical examination** that includes blood pressure, pulse, and respiration measurements, one or more of the following imaging tests are ordered.

Tests

A computed tomography scan (CT scan) or a **magnetic resonance imaging** (MRI) scan usually is the first imaging test. CT or MRI can rule out other problems such as a tumor or **subdural hematoma** that can mimic the symptoms of a TIA. A CT scan also can uncover aneurysms and arteriovenous malformation, both of which are blood vessel abnormalities that can cause bleeding in the brain.

Another useful imaging test is carotid ultrasonography, a noninvasive procedure that allows examination of the interior of the carotid artery. This examination can detect carotid stenosis, a condition in which the artery is abnormally narrow because of atherosclerosis. Ultrasonography is very reliable in identifying stenosis, but it does not give enough information to accurately assess the degree of stenosis. Because treatment depends on the degree of stenosis, treatment decisions cannot be based on ultrasonography. Another type of ultrasonography, called **transcranial Doppler ultrasonography**, is used to detect stenosis of the blood vessels within the brain and in the vertebrobasilar arteries.

KEY TERMS

Angioplasty—A medical procedure in which a catheter, or thin tube, is threaded through blood vessels. The catheter is used to place a balloon or stent (a small metal rod) at an area of stenosis and expand it mechanically.

Arteriography—A medical test in which an x-ray visible dye is injected into blood vessels. This dye allows the blood vessels to be imaged with x rays.

Atherosclerosis—A build-up of fatty tissue called plaque inside arteries that can impede or block blood flow.

Carotid artery—One of the major blood vessels leading to the brain; it runs up the front of the neck.

Echocardiography—A type of ultrasonography that is used to create an image of the heart and its functioning.

Endarterectomy—A surgical procedure in which diseased tissue and atherosclerotic plaque are removed from the inside of an artery.

Ischemia—A condition in which blood flow is cut off or restricted from a particular area. The surrounding tissue, starved of oxygen and nutrients, dies.

Microemboli—Small blot clots in the bloodstream.

Platelets—Tiny cells in the blood that help form blood clots.

Stenosis—The narrowing of an opening or passageway in the body. In arteries, stenosis is caused by a build-up of atherosclerotic plaque, disease, or other disorder.

Stroke—A condition in which blood flow to the brain has been blocked, thereby causing brain cells to die from lack of oxygen and nutrients; also called a "brain attack."

Ultrasonography—A medical test in which sound waves are directed against internal structures in the body. As sound waves bounce off the internal structure, they create an image on a video screen.

Vertebrobasilar arteries—Major blood vessels that lead to the brain. They are located at the base of the skull at the back of the head.

Procedures

If stenosis is identified, a further test called cerebral arteriography may be done. This test is not done if the individual is in poor health, because it may be too risky. Arteriography involves injecting a special dye into the blood vessels that makes them visible on x rays. This procedure also is used to find suspected problems with blood vessels in the brain. Because it is an invasive procedure, complications can arise. Typically, these complications are minor and temporary. In a very small percentage of people with cardiovascular disease, the procedure may cause serious complications, such as stroke.

Although TIAs affect the brain, the ultimate cause of the problem may be found in the heart. Heart disease or damage to the heart's blood vessels is assessed by **echocardiography**. Echocardiography is a type of ultrasonography and is a noninvasive procedure.

Treatment

Treatment is aimed at preventing further TIAs and especially at preventing a stroke. The particular therapy depends on the root cause of the TIA and is not begun until this cause is identified. If possible, drug therapy is the preferred method of treating TIAs. Surgical intervention may be required if an individual's situation is not likely to respond to medication or if medication has failed.

Drugs

Anticlotting drugs such as **aspirin** or cloplidgrel (Plavix) usually are given to reduce the chance of platelets forming clumps in the blood. These drugs are intended for long-term use. Anticoagulant (blood thinner) drugs such as warfarin (Coumadin) may be prescribed to keep blood from clotting. Other drugs may be prescribed to relax the smooth muscles of the arteries. Cholesterol-lowering drugs (statins) may be recommended, and conditions such as high blood pressure (**hypertension**) and **diabetes mellitus** that can worsen **vascular disease** will be treated.

Surgery

If carotid arteriography reveals at least a 70% blockage of the carotid artery, surgical treatment usually is recommended. The particular surgical method is called carotid **endarterectomy**. In endarterectomy, the artery is opened and the material clogging it is removed. Another procedure, called balloon **angioplasty**, has been suggested for treating carotid stenosis, but it is not as widely used. This procedure is performed by threading a thin tube through the blood vessel to the site that is clogged.

A balloon or a stent (a slender rod) is then passed through the tube to mechanically widen the narrowed area. This procedure is successfully used in other blood vessels in the body, but there is some worry that using it close to the brain may be too dangerous. Surgical treatment of blockage of the vertebrobasilar arteries is not usually recommended.

Home remedies and lifestyle changes

Treatment of TIAs also focuses on underlying problems. High blood pressure, heart disease, and high levels of blood lipids all require medical intervention. Condition-specific medications often are prescribed and lifestyle changes are strongly encouraged. These may include:

- losing weight if necessary and maintaining a healthy weight
- stopping smoking
- avoiding alcohol or consuming alcohol in moderation
- exercising moderately but regularly (5 days a week)
- eating a diet low in animal fats and sweets and high in fresh fruits, vegetables, and fiber
- controlling high blood pressure through salt (sodium) restriction, exercise, and medications as necessary
- controlling diabetes through exercise, diet, and medication as necessary by monitoring blood glucose levels regularly

Prognosis

One-third of TIAs are followed by stroke in the next five years; in the other two-thirds, the TIAs may either continue or disappear on their own. However, because of the risk of stroke-related disability and death, all TIAs should be treated as emergency medical situations.

Medical treatment significantly decreases the risk of stroke for people who experience one or more TIAs. Anti-platelet therapy reduces risk as much as 31%. Carotid endarterectomy also substantially reduces stroke risk. The procedure itself carries some risk, but the complication rate is less than 5%. The risk of complication can be lowered by choosing to have the procedure done in a facility experienced with it and by a surgeon with a low complication rate.

Prevention

Treatment for TIAs is complemented by lifestyle changes. These practices also may prevent TIAs and strokes from ever occurring. Doctors and other healthcare providers universally recommend that individuals stop **smoking** and consume alcohol in moderation. Regular health checkups can detect high blood pressure, heart disease, and other underlying problems. Adhering to treatment for these problems can help minimize TIA and stroke risks. Finally, maintaining a healthy weight and engaging in regular **exercise** as able are strongly recommended.

Transplant reaction screening test *see* **Cytomegalovirus antibody screening test**

Transplant surgery

Definition

Transplant surgery is the surgical removal of organs, tissue, or blood products from a donor and surgically placing or infusing them into a recipient. There are four categories of transplantation, classified by tissue origin: autograft (donor and recipient are the same person); isograft or syngeneic graft (donor and recipient are genetically identical, as in identical twins); allograft or homograft (donor and recipient are genetically unrelated but belong to the same species, i.e., both are human

KEY TERMS

Antibody—A substance produced by the immune system in response to specific antigens, thereby helping the body fight infection and foreign substances. An antibody screen involves mixing the white blood cells of the donor with the serum of the recipient to determine if antibodies in the recipient react with the antigens of the donor.

Autologous blood—The patient's own blood, drawn and set aside for use during surgery in case a transfusion is needed.

Bone densitometry test—A test that quickly and accurately measures the density of bone.

Brain death—Irreversible cessation of brain function. Patients with brain death have no potential capacity for survival or for recovery of any brain function.

Cadaveric donor—An organ donor who has recently died of causes not affecting the organ intended for transplant.

Compatible donor—A person whose tissue and blood type are the same as the recipient's.

Confirmatory typing—Repeat tissue typing to confirm the compatibility of the donor and patient before transplant

Donor—A person who supplies organ(s), tissue or blood to another person for transplantation.

Harvesting—The process of removing tissues or organs from a donor and preserving them for transplantation.

Hemodilution—A technique in which the fluid content of the blood is increased without increasing the number of red blood cells.

Human leuckocyte antigen (HLA)—A group of protein molecules located on bone marrow cells that can provoke an immune response. A donor's and a recipient's HLA types should match as closely as possible to prevent the recipient's immune system from attacking the donor's marrow as a foreign material that does not belong in the body.

Immunosuppression—The use of medications to suppress the immune system to prevent organ rejection.

Organ procurement—The process of donor screening, and the evaluation, removal, preservation, and distribution of organs for transplantation.

Pulmonary function test—A test that measures the capacity and function of the lungs as well as the blood's ability to carry oxygen. During the test, the patient breathes into a device called a spirometer.

Rejection—An immune response that occurs when a transplanted organ is viewed as a foreign substance by the body. If left untreated, rejection can lead to organ failure and even death.

beings) and xenograft or heterograft (donor and recipient belong to different species, i.e., chimpanzee or rabbit tissues have been used in humans on an experimental basis).

Purpose

Transplant surgery is a treatment option for diseases or conditions that have not improved with other medical treatments and have led to organ failure or injury. Transplant surgery is generally reserved for people with end-stage disease who have no other options.

The decision to perform transplant surgery is based on the patient's age, general physical condition, specific diagnosis, and stage of the disease. Transplant surgery is not recommended for patients who have liver, lung, or kidney problems; poor leg circulation; **cancer**; or chronic infections.

Demographics

The former typical cut-off age for a transplant recipient ranged between 40 and 55 years; however, people aged 50–65 consitiute the fastest-growing age group added to the transplant waiting list. A person's general health is usually a more important factor. In addition, the percentage of transplant recipients over age 50 has increased since 1996. Expanded-criteria kidney donations are responsible for many of these later-life transplants. Kidneys in this category have been donated from people who in the past would not be considered optimum donors due to age or certain medical conditions. Studies have shown that older persons with kidney failure fare better with an expanded-criteria kidney transplant than by remaining on dialysis.

On average, 66 people receive transplants every day from either a living or deceased donor. Between January

and October 2009, 23,846 transplants were performed in the United States; 18,404 organs came from deceased donors, while 5,442 came from living donors.

The national waiting list for most transplanted organs continues to grow every year, even though the number of recipients waiting for a heart transplant has leveled off in recent years, and the waiting list for heart-lung transplants has decreased over the past few years. As of January 2010, there were about 105,300 eligible recipients waiting for an organ transplant in the United States.

Description

Organ donors

Organ donors are classified as living donors or cadaveric (non-living) donors. All donors are carefully screened to make sure there is a suitable blood type match and to prevent any transmissible diseases or other complications.

LIVING DONORS. Living donors may be family members or biologically unrelated to the recipient. From 1992 to 2001, the number of biologically unrelated living donors increased tenfold. Living donors must be physically fit, in good general health, and have no existing disorders such as diabetes, high blood pressure, cancer, **kidney disease**, or heart disease. Of all the organs transplanted in 2008, about 22% came from living donors. Organs that can be donated from living donors include:

- Single kidneys. In 2009, about one third of all kidney transplants came from living donors. There is little risk in living with one kidney because the remaining kidney compensates for and performs the work of both.
- Liver. Living donors can donate segments of the liver because the organ can regenerate and regain full function.
- Lung. Living donors can donate lobes of the lung although lung tissue does not regenerate.
- Pancreas. Living donors can donate a portion of the pancreas even though the gland does not regenerate.
- Intestines. Living donors can donate a portion of their intestine.

Organs donated from living donors eliminate the need to place the recipient on the national waiting list. Transplant surgery can be scheduled at a mutually acceptable time rather than performed under emergency conditions. In addition, the recipient can begin taking immunosuppressant medications two days before the transplant surgery to prevent the risk of rejection. Living donor transplants are often more successful than cadaveric donor transplants because there is a better tissue match between the donor and recipient. The living donor's medical expenses are usually covered by the organ recipient's insurance company, but the amount of coverage may vary.

CADAVERIC OR DECEASED DONORS. Organs from cadaveric donors come from people who have recently died and have willed their organs before **death** by signing an organ donor card, or are brain-dead. The donor's family must give permission for **organ donation** at the time of death or diagnosis of brain death. Cadaveric donors may be young adults with traumatic head injuries, or older adults suffering from a **stroke**. The majority of deceased donors are older than the general population.

Transplant procedures

ORGAN HARVESTING. Harvesting refers to the process of removing cells or tissues from the donor and preserving them until they are transplanted. If the donor is deceased, the organ or tissues are harvested in a sterile operating room. They are packed carefully for transportation and delivered to the recipient via ambulance, helicopter, or airplane. Organs from deceased donors should be transplanted within a few hours of harvesting. After the recipient is notified that an organ has become available, he or she should not eat or drink anything.

When the organ is harvested from a living donor, the recipient's transplant surgery follows immediately after the donor's surgery. The recipient and the donor should not eat or drink anything after midnight the evening before the scheduled operation.

PREOPERATIVE PROCEDURES. After arriving at the hospital, the recipient will have a complete physical and such other tests as a **chest x ray**, blood tests, and an electrocardiogram (EKG) to evaluate his or her fitness for surgery. If the recipient has an infection or major medical problem, or if the donor organ is found to be unacceptable, the operation will be canceled.

The recipient will be prepared for surgery by having the incision site shaved and cleansed. An intravenous tube (IV) will be placed in the arm to deliver medications and fluids, and a sedative will be given to help the patient relax.

TRANSPLANT SURGERY. After the patient has been brought to the operating room, the anesthesiologist will administer a general anesthetic. A central venous catheter may be placed in a vein in the patient's arm or groin. A breathing tube will be placed in the patient's throat. The breathing tube is attached to a mechanical ventilator that expands the lungs during surgery.

The patient will then be connected to a heart-lung bypass machine, also called a cardiopulmonary bypass pump, which takes over for the heart and lungs during the surgery. The heart-lung machine removes carbon dioxide from the blood and replaces it with oxygen. A tube is inserted into the patient's aorta to carry the oxygenated blood from the bypass machine back to the heart for circulation to the body. A nasogastric tube is placed to drain stomach secretions, and a urinary catheter is inserted to drain urine during the surgery.

The surgeon carefully removes the diseased organ and replaces it with the donor organ. The blood vessels of the donated organ are connected to the patient's blood vessels, allowing blood to flow through the new organ.

Diagnosis/Preparation

Pre-transplant evaluation

Several tests are performed before the transplant surgery to make sure that the patient is eligible to receive the organ and to identify and treat any problems ahead of time. The more common pre-transplant tests include:

- tissue typing
- blood tests
- chest x ray
- pulmonary function tests
- computed tomography (CT) scan
- heart function tests (electrocardiogram, echocardiogram, and cardiac catheterization)
- sigmoidoscopy
- bone densitometry test

The pre-transplant evaluation usually includes a dietary and social work assessment. In addition, the patient must undergo a complete dental examination to reduce the risk of infection from bacteria in the mouth.

Insurance considerations

Organ transplantation is an expensive procedure. Insurance companies and health maintenance organizations (HMOs) may not cover all costs. Many insurance companies require precertification letters of medical necessity. As soon as transplantation is discussed as a treatment option, the patient should contact his or her insurance provider as soon as possible to determine what costs will be covered. In the United States as of early 2008, a kidney transplant cost as much as $100,000, a liver transplant $250,000, and a heart transplant $860,000. There are, however, organizations that can assist with raising funds to cover the cost of transplantation, such as the National Foundation for Transplants and the National Transplant Assistance Fund and Catastrophic Injury Program.

Patient education and lifestyle changes

Before undergoing transplant surgery, the transplant team will ensure that the patient understands the potential benefits and risks of the procedure. In addition, a team of health care providers will review the patient's social history and psychological test results to ensure that he or she is able to comply with the regimen that is needed after transplant surgery. An organ transplant requires major lifestyle changes, including dietary adjustments, complex drug treatments, and frequent examinations. The patient must be committed to making these changes in order to become a candidate for transplant. Most transplant centers have extensive patient education programs.

Smoking cessation is an important consideration for patients who use tobacco. Many transplant programs require the patient to be a nonsmoker for a certain amount of time (usually six months) before he or she is eligible to participate in the pre-transplant screening evaluation. The patient must also be committed to avoid tobacco products after the transplant.

Informed consent

Patients are legally required to sign an informed consent form prior to transplant surgery. Informed consent signifies that the patient is a knowledgeable participant in making healthcare decisions. The doctor will discuss all of the following with the patient before he or she signs the form: the nature of the surgery; reasonable alternatives to the surgery; and the risks, benefits, and uncertainties of each option. Informed consent also requires the doctor to make sure that the patient understands the information that has been given.

Finding a donor

After the patient has completed the pre-transplant evaluation and has been approved for transplant surgery, the next step is locating a donor. Organs from cadaveric donors are located through a computerized national waiting list maintained by the United Network for Organ Sharing (UNOS) to assure equal access to and fair distribution of organs. When a deceased organ donor is identified, a transplant coordinator from an organ procurement organization enters the donor's data in the UNOS computer. The computer then generates a list of potential recipients. This list is called a match run. Factors affecting a potential organ

recipient's ranking on the match run list include: tissue match, blood type, size of the organ, length of time on the waiting list, immune status, and the geographical distance between the recipient and donor. For some transplants, such as heart, liver, and intestinal segments, the degree of medical urgency is also taken into consideration.

The organ is offered to the transplant team of the first person on the ranked waiting list. The recipient must be healthy enough to undergo surgery, available, and willing to receive the organ transplant immediately. The matching process involves cross matching, performing an antibody screen and a host of other tests.

Donor searching can be a long and stressful process. A supportive network of friends and family is important to help the patient cope during this time. The healthcare provider or social worker can also put the patient in touch with support groups for transplant patients.

Contact and travel arrangements

The patient must be ready to go to the hospital as soon as possible after being notified that an organ is available. A suitcase should be kept packed at all times. Transportation arrangements should be made ahead of time. If the recipient lives more than a 90-minute drive from the transplant center, the transplant coordinator will help make transportation arrangements for the recipient and one friend or family member.

Because harvested organs cannot be preserved for more than a few hours, the transplant team must be able to contact the patient at all times. Some transplant programs offer a pager rental service, to be used only for receiving the call from the transplant center. The patient should clear travel plans with the transplant coordinator before taking any trips.

Blood donation and conservation

Some transplant centers allow patients to donate their own blood before surgery, which is known as autologous donation. Autologous blood is the safest blood for **transfusion**, since there is no risk of disease transmission. Preoperative donation is an option for patients receiving an organ from a living donor, since the surgery can be scheduled in advance. In autologous donation, the patient donates blood once a week for one to three weeks before surgery. The blood is separated and the blood components needed are reinfused during the operation.

In addition to preoperative donation, there are several techniques for minimizing the patient's blood loss during surgery:

- Intraoperative blood collection. The blood lost during surgery is processed, and the red blood cells are reinfused during or immediately after surgery.
- Immediate preoperative hemodilution. The patient donates blood immediately before surgery to decrease the loss of red blood cells during the operation. The patient is then given fluids to restore the volume of the blood.
- Postoperative blood collection. The blood lost from the incision following surgery is collected and reinfused after the surgical site has been closed.

Aftercare

Inpatient recovery

A transplant recipient can expect to spend three to four weeks in the hospital after surgery. Immediately following the operation, the patient is transferred to an intensive care unit (ICU) for close monitoring of his or her vital signs. When the patient's condition is stable, he or she is transferred to a hospital room, usually in a specialized transplant unit. The IV in the patient's arm, the urinary catheter, and a dressing over the incision remain in place for several days. A chest tube may be placed to drain excess fluids. Special stockings may be placed on the patient's legs to prevent **blood clots** in the deep veins of the legs. A breathing aid called an incentive spirometer is used to help keep the patient's lungs clear and active after surgery.

Medications to relieve **pain** will be given every three to four hours, or through a device known as a PCA (patient-controlled anesthesia). The PCA is a small pump that delivers a dose of medication into the IV when the patient pushes a button. The transplant recipient will also be given immunosuppressive medications to prevent the risk of organ rejection. These medications are typically taken by the recipient for the rest of his or her life.

A 2–4 week waiting period is necessary before the transplant team can evaluate the success of the procedure. Visitors are limited during this time to minimize the risk of infection. The patient will be given intravenous antibiotic, antiviral and antifungal medications, as well as blood and platelet transfusions to help fight off infection and prevent excessive bleeding. Blood tests are performed daily to monitor the patient's kidney and liver function, as well as his or her nutritional status. Other tests are performed as needed.

Outpatient recovery

After leaving the hospital, the transplant recipient will be monitored through home or outpatient visits for as long as a year. Medication adjustments are often necessary, but barring complications, the recipient can return to normal activities about 6–8 months after the transplant.

Proper outpatient care includes:

- taking medications exactly as prescribed
- attending all scheduled follow-up visits
- contacting the transplant team at the first signs of infection or organ rejection
- having blood drawn regularly
- following dietary and exercise recommendations
- avoiding rough contact sports and heavy lifting
- taking precautions against infection
- avoiding pregnancy for at least a year

Risks

Short-term risks following an organ transplant include **pneumonia** and other infectious diseases; excessive bleeding; and liver disorders caused by blocked blood vessels. In addition, the new organ may be rejected, which means that the patient's immune system is attacking the new organ. Characteristic signs of rejection include **fever**, rash, **diarrhea**, liver problems, and a compromised immune system. Transplant recipients are given immunosuppressive medications to minimize the risk of rejection. In most cases, the patient will take these medications for the rest of his or her life.

Long-term risks include an elevated risk of cancer, particularly skin cancer. An estimated 6–8% of transplant patients develop cancer over their lifetime as compared to less than 1% in the general population.

There is a very small risk of infection from a transplanted organ, even though donors in the United States and Canada are carefully screened. In 2007, the Centers for Disease Control and Prevention (CDC) reported a case in which four organ recipients in the Chicago area developed **hepatitis C** and HIV infection from a high-risk donor. The diseases did not show up on screening tests because the donor contracted them about three weeks before his death, when there were not enough antibodies in his blood to be detected by present tests.

Normal results

In a successful organ transplant, the patient returns to a more nearly normal lifestyle with increased strength and stamina.

Morbidity and mortality rates

Mortality figures for transplant surgery include recipients who die before a match with a suitable donor can be found. About 17 patients die every day in the United States waiting for a transplant.

The Scientific Registry of Transplant Recipients gives the first-year survival rates for transplant surgery as follows:

- 97% of pancreas transplant recipients
- 95% of kidney transplant and kidney/pancreas recipients
- 90% of autologous bone marrow transplant patients
- 86% of liver transplant patients
- 85% of heart transplant patients
- 77% of lung transplant patients
- 70% of allogeneic bone marrow transplant patients

Three-year survival rates are:

- 91% for kidney transplant patients
- 87% for pancreas and kidney/pancreas transplant patients
- 80% for liver transplant patients
- 79% for heart transplant patients
- 59% for lung transplant patients

As of early 2010, about 190,000 Americans are living with a transplanted organ.

Alternatives

Clinical trials

Available alternatives to transplant surgery depend upon the individual patient's diagnosis and severity of illness. Some patients may be eligible to participate in clinical trials, which are research programs that evaluate a new medical treatment, drug or device. As of early 2010 the NIH has 208 studies of organ transplantation that are seeking new volunteers.

Complementary and alternative (CAM) therapies

Complementary therapies can be used along with standard treatments to help alleviate the patient's pain; strengthen muscles; and decrease depression, **anxiety**, and **stress**. Before trying a complementary treatment, however, patients should check with their doctors to make sure that it will not interfere with standard therapy or cause harm. Alternative approaches that have helped transplant recipients maintain a positive mental attitude both before and after surgery include **meditation**, **biofeedback**, and various relaxation techniques. **Massage**

therapy, **music therapy**, **aromatherapy**, and **hydrotherapy** are other types of treatment that can offer patients some pleasant sensory experiences as well as relieve pain. **Acupuncture** has been shown in a number of NIH-sponsored studies to be effective in relieving **nausea** and **headache**, as well as chronic muscle and joint pain. Some insurance carriers cover the cost of acupuncture treatments.

Transplantation *see* **Corneal transplantation; Hair transplantation; Heart transplantation; Kidney transplantation; Lung transplantation; Pancreas transplantation**

Transposition of the great arteries

Definition

Transposition of the great arteries is a birth defect causing a fatal condition in which there is a reversal, or switch, in the truncal connections of the two main (great) blood vessels to the heart, the aorta and pulmonary artery.

Demographics

In the United States, transposition of the great artery is one of the most common congenital heart defects It is more common in males than in females, race is not a factor, and it affects about 40 out of every 100,000 babies born. The mortality rate in untreated patients is approximately 30% in the first week, 50% in the first month, and 90% by the end of the first year.

With improved diagnostic, medical, and surgical techniques, the overall short-term and midterm survival rate exceeds 90%.

Description

There are two great arteries, the pulmonary artery and the aorta. Normally, the pulmonary artery carries blood from the right ventricle to the lungs. The aorta carries blood from the left ventricle to the vessels of the rest of the body.

Normally, blood returning to the heart is depleted in oxygen. It goes first to the right atrium of the heart and then to the right ventricle where it is pumped to the lungs. While in the lungs, the blood picks up more oxygen. After the lungs, the blood flows to the left atrium, then the left ventricle, which pumps the blood out through the aorta to the rest of the body, thereby supplying the body with oxygenated blood.

Transposition of the great arteries results in oxygen-depleted blood going to the body. The reason is that the connection of the two great arteries is reversed. In this case, the aorta is connected to the right ventricle. Blood returning to the heart goes to the right atrium and ventricle, which is normal. Then, when the right ventricle pumps the blood out, it goes into the aorta for distribution throughout the body. At the same time, blood in the lungs goes to the left atrium, the left ventricle, but then back to the lungs. This happens because the pulmonary artery is connected to the left ventricle. The result is that highly-oxygenated blood keeps recycling through the lungs, while oxygen-depleted blood recycles through the body without going through the lungs to reoxygenate.

This condition develops during the fetal stage and must be treated promptly after birth if the newborn is to survive. The newborn can survive for a few days because the foramen ovale, a small hole in the septum that separates the two atria, is open, allowing some oxygenated blood to escape and mix into the blood that is being pumped throughout the body. However, the foramen ovale normally closes within a few days after birth.

Causes and symptoms

Transposition of the great arteries is a birth defect that occurs during fetal development. There is no identifiable disease or cause. The main symptom is blueness of the skin caused by a general lack of oxygen in the body's tissues. Other symptoms include, **shortness of breath**, poor feeding, and chubbing of the fingers or toes.

KEY TERMS

Aorta—The biggest artery in the body, receiving blood directly from the heart.

Artery—A blood vessel that carries blood away from the heart to the rest of the body.

Atrium—One of the two upper chambers of the heart.

Blood vessels—General term for arteries, veins, and capillaries that transport blood throughout the body.

Pulmonary artery—The blood vessel that delivers blood from the heart to the lungs.

Ventricle—A cavity, as in the brain or heart. The right ventricle of the heart drives blood from the heart into the pulmonary artery, which supplies blood to the lung.

Diagnosis

Diagnosis is made immediately after birth, when it is observed that the newborn is lacking oxygen. This is noted by the bluish color of the newborn, indicating **cyanosis**, a lack of oxygen. A definite diagnosis is made by x ray, **electrocardiography** (ECG), and **echocardiography**.

Treatment

The only treatment for this condition is prompt heart surgery shortly after birth. In surgery, the two great arteries are reconnected to their proper destination. This restores the normal blood flow pattern. The coronary arteries are also reconnected, so that they can supply blood to the heart itself. During the procedure at birth, the baby will receive prostaglandin through an IV (intravenous line). This medication helps the blood flow through the lungs and body. A procedure using **cardiac catheterization** may also be needed to create a large hole in the atrial septum to allow blood to mix. In many hospitals, a type of surgery called an arterial switch procedure can be used to permanently correct the problem within the first week of life. This surgery switches the great arteries back to the normal position along with the coronary arteries.

Prognosis

Improvement in symptoms, along with growth and development is seen after surgical correction of the

defect. However, left untreated, this disease can be fatal within the first weeks of life.

Prevention

Because there is no identifiable cause, there is no way to prevent this condition. However, women who plan to become pregnant should be immunized against **rubella** if they are not already immune. Avoiding alcohol, eating healthy, and controlling diabetes both before and during **pregnancy** may also be helpful.

Transurethral bladder resection

Definition

Transurethral bladder resection is a surgical procedure, performed under **sedation** or anesthesia, with a lighted tube inserted through the urethra (the small tube-like structure that allows urine to empty from the bladder), into the bladder. It plays both a diagnostic and therapeutic role in the treatment of bladder cancers.

Purpose

Tranurethral resection is the initial form of treatment for bladder cancers. The procedure is performed to remove and examine bladder tissue and/or tumor. It may also serve to remove lesions and be the only treatment necessary for noninvasive tumors.

Description

For this procedure, a lighted tube (resectoscope) is inserted through the urethra, into the bladder. A clear solution is infused to maintain visibility, and the tumor or tissue to be examined is cut away using an electric current. Tumor and muscle fibers are biopsied (a sample is cut out and examined, usually under a microscope) in order to evaluate the depth of tissue involvement, while avoiding perforation of the bladder wall. Every attempt is made to remove all visible tumor tissue, along with a small border of healthy tissue. The resected tissue is examined under the microscope for diagnostic purposes. An indwelling catheter may be inserted to ensure adequate drainage of the bladder postoperatively. At this time, interstitial **radiation therapy** may be initiated if necessary.

Preparation

Preoperative x rays with dye studies are helpful as a guide in determining the character and extent of tumor involved. As with any surgical procedure, the patient is asked to sign a consent form after the procedure is thoroughly explained.

Aftercare

As with any surgical procedure, blood pressure and pulse will be monitored. Urine is expected to be blood-tinged in the early postoperative period. Continuous bladder irrigation (rinsing) may be used for approximately 24 hours after surgery. Most operative sites should be completely healed in three months. The patient is followed closely for possible recurrence with visual examination, using a special viewing device (cystoscope) at regular intervals as the physician deems necessary.

Abnormal results

Complications of the procedure may include bleeding, which may require bladder irrigation postoperatively, during which time the patient's activity is limited to bedrest. Perforation of the bladder is another risk, in which case the urinary catheter is left in place for four to five days postoperatively. The patient is started on antibiotic therapy preventively. If the bladder is lacerated, accompanied by spillage of urine into the abdomen, an abdominal incision may be required.

Transvaginal ultrasound

Definition

Transvaginal ultrasound is a imaging technique used to create a picture of the genital tract in women. The hand-held device that produces the ultrasound waves is inserted directly into the vagina, close to the pelvic structures, thus often producing a clearer and less distorted image than obtained through transabdominal ultrasound technology, where the probe is located externally on the skin of the abdomen.

Purpose

Transvaginal ultrasound can be used to evaluate problems or abnormalities of the female genital tract. It may provide more accurate information than transabdominal ultrasound for women who are obese, for women who are being evaluated or treated for **infertility**, or for women who have difficulty keeping a full bladder. However, it does provide a view of a smaller area than the transabdominal ultrasound. Types of conditions or abnormalities that can be examined include:

- the endometrium of women with infertility problems or who are experiencing abnormal bleeding
- sources of unexplained pain
- congenital malformations of the ovaries and uterus
- ovarian cysts and tumors
- pelvic infections, such as pelvic inflammatory disease
- bladder abnormalities
- a misplaced IUD (intrauterine device)
- other causes of infertility

Transvaginal ultrasound can also be used during **pregnancy**. Its capability of producing more complete images means that it is especially useful for identifying **ectopic pregnancy**, fetal heartbeat, and abnormalities of the uterus, placenta, and associated pelvic structures.

Transvaginal ultrasound is performed by an ultrasound technologist, who is supervised by a radiologist or a specialist such as an obstetrician.

Precautions

Studies have shown that ultrasound is not hazardous and has no harmful side effects.

Description

A ultrasound, or sonogram, is a procedure that utilizes reflected sound waves to produce a picture of organs and structures within the body. A transducer sends out high-pitched sounds, sounds that are above the range of human hearing, that are reflected back to the transducer. A computer is used to analyze the sound waves, transforming them into a picture (which is called a sonogram, echogram, or ultrasound scan) on a video monitor. These pictures can be saved as a permanent record of the test.

A transvaginal ultrasound is used for looking at organs and structures within the pelvic area that are solid and uniform, like the uterus, and ovaries, or for organs that are fluid-filled, like the bladder. Mineralized structures, like bones, or air-filled organs, such as the intestines, do not show up well on a sonogram and may disrupt the ultrasound beam so that deeper organs and structures cannot be seen clearly.

The transvaginal transducer that produces the ultrasound waves is shaped to fit within a woman's vagina. It is lubricated and covered with a sheath such as a condom. A woman should tell the health care provider if she is allergic to latex so that a latex-free cover can be applied to the transducer before it is inserted into the vagina.

Sometimes a woman may have both transvaginal and transabdominal ultrasound scans done to obtain a complete evaluation of the pelvic area.

Preparation

There is no special preparation required by a woman before a transvaginal ultrasound. She can continue to take medications prescribed by her health care provider, although she should not drink liquids for four hours before the test. A full bladder is not required for a transvaginal ultrasound, as is required for a transabdominal ultrasound. The test can be administered during any stage of the woman's menstrual cycle.

During the procedure, the woman lies on her back, with her hips slightly raised. The thin, lubricated tip of the transducer is inserted gently into the vagina. The transducer is moved and rotated to adjust the view of the pelvic structures displayed on the monitor. The woman must lie very still during the ultrasound scan. She may feel a mild discomfort from the pressure of the vaginal transducer. The procedure usually takes from 15 to 30 minutes.

Occasionally, **hysterosonography** is done on a nonpregnant woman to evaluate the inside of the uterus (endometrial cavity) and fallopian tubes by filling the uterus with fluid during a transvaginal ultrasound.

KEY TERMS

Ectopic pregnancy—Pregnancy that develops outside the uterus, usually in one of the fallopian tubes.

Endometrium—The mucous membrane that makes up the inner layer of the uterine wall.

Gestational trophoblastic disease—A rare, aggressive, malignant, often metastatic (spreading to other organs) cancer in women of childbearing age in which cancer cells grow in the tissues that are formed in the uterus after conception.

Intrauterine device (IUD)—Contraceptive device consisting of a piece of bent plastic or metal that is inserted through the vagina into the uterus.

Transabdominal ultrasound—A small handheld instrument called a transducer is passed back and forth over the pelvic area to provide images of the abdomen.

Ovarian torsion—Twisting of the ovary due to the influence of another condition or disease, resulting in extreme lower abdominal pain.

Pelvic inflammatory disease (PID)—Inflammation of the female genital tract, especially of the fallopian tubes, caused by any of several microorganisms, chiefly chlamydia and gonococci, and characterized by severe abdominal pain, high fever, vaginal discharge, and in some cases destruction of tissue that can result in sterility.

Placental abruption—Premature separation of the placenta from the uterus.

Placenta previa—A low-lying placenta that covers part or all of the inner opening of the cervix. This can result in heavy bleeding during labor and delivery, which can be dangerous for mother and baby.

Aftercare

There is a slight risk of infection associated with a transvaginal ultrasound, especially if a biopsy was done in conjunction with the procedure. Therefore the patient should be aware of symptoms of an infection and seek care from a health care professional as necessary.

Risks

Since no ionizing radiation is associated with transvaginal ultrasound, there has been no documented adverse effects on patients or their fetuses with the use of the procedure.

Normal results

In a normal transvaginal ultrasound, the pelvic structures or organs or the fetus are found to have no abnormalities.

Abnormal results

Abnormal ultrasound results can be due to a variety of conditions and diseases. In non-pregnant women, these abnormal results may include:

- cancerous tumors or non-cancerous growths of the uterus, ovaries, vagina, or other pelvic structures
- ovarian torsion
- infections such as PID
- congenital malformations.

In pregnant women, the following abnormalities may be diagnosed through transvaginal ultrasound:

- ectopic pregnancies
- multiple pregnancies
- fetal death
- short cervix length, which may indicate the risk of preterm labor
- placental abnormalities such as placental previa and placental abruption
- tumors of pregnancy, including gestational trophoblastic disease.

A biopsy is needed to determine whether a tumor that is found during the transvaginal ultrasound scan is cancerous or non-cancerous.

Transverse myelitis

Definition

Transverse myelitis (TM) is an uncommon neurological syndrome caused by inflammation (a protective response which includes swelling, **pain**, heat, and redness) of the spinal cord, characterized by weakness, back pain, and bowel and bladder problems. It affects one to five persons per million.

Description

TM affects the entire thickness of the spinal cord, producing both sensory and movement problems. It is believed to be linked to the immune system, which may be prompted to attack the body's own spinal cord. Striking rapidly without warning, its effects can be devastating.

Causes and symptoms

Transverse myelitis has many different causes, often triggered by a variety of viral and bacterial infections (especially those associated with a rash such as **measles** or **chickenpox**). Once the infection subsides, the inflammation in the cord begins. About a third of patients experience a flu-like illness with **fever** about the time they develop symptoms of TM. Sometimes, there appears to be a direct invasion of, and injury to, the spinal cord by an infectious agent (such as herpes zoster or the **AIDS** virus).

TM can also accompany a variety of diseases that break down tissue that surrounds and insulates the nerves (demyelinating diseases), such as **multiple sclerosis** (MS).

Some toxic substances, such as carbon monoxide, lead, or arsenic, can cause a type of myelitis characterized by inflammation followed by hemorrhage or bleeding that destroys the entire circumference of the spinal cord. Other types of myelitis can be caused by poliovirus; herpes zoster; **rabies**, **smallpox** or **poliovaccination**; or parasitic and fungal infections.

Many experts believe that TM can occur without any apparent cause, probably as the result of an autoimmune process. This means that a person's immune system attacks the spinal cord, causing inflammation and tissue damage.

Regardless of the cause of the myelitis, onset of symptoms is sudden and rapid. Problems with movement and sensation appear within one or two days after inflammation begins. Symptoms include soft (flaccid) **paralysis** of the legs, with pain in the lower legs or back, followed by loss of feeling and sphincter (muscles which close an opening, as in the anus) control. The earliest symptom may be a girdle-like sensation around the trunk.

The extent of damage occuring will depend on how much of the spinal cord is affected, but TM rarely involves the arms. Severe spinal cord damage also can lead to **shock**.

KEY TERMS

Demyelinating disorders—A group of diseases characterized by the breakdown of myelin, the fatty sheath surrounding and insulating nerve fibers. This breakdown interferes with nerve function, and can result in paralysis. Multiple sclerosis is a demyelinating disorder.

Myelogram—An x-ray examination of the brain and spinal cord with the aid of a contrast dye, to look for tumors or spinal cord injury.

Diagnosis

A doctor will suspect transverse myelitis in any patient with a rapid onset of paralysis. Medical history, **physical examination**, brain and spinal cord scans, myelogram, spinal tap, and blood tests are used to rule out other neurological causes of symptoms, such as a tumor. If none of these tests suggest a cause for the symptoms, the patient is presumed to have transverse myelitis.

Treatment

There is no effective treatment for transverse myelitis, but any underlying infection must be treated. After this, the focus of care shifts from diagnosis and treatment to learning how to live with the effects of the syndrome. Patients are helped to cope psychologically with new limitations, and are given physical **rehabilitation**.

Physical adaptations include learning to cope with bowel and bladder control, sexuality, inability to control muscles (spasticity), mobility, pain, and activities of daily living (such as dressing).

As nerve impulses from the spinal cord are often scrambled and misinterpreted by the brain as pain, painkillers are given to ease discomfort. Antidepressants or anticonvulsants may also help.

Prognosis

The prognosis depends on how much of the cord was damaged. Some people recover completely, while others have lasting problems and need help in learning how to cope with activities of daily living. People who develop spastic reflexes early in the course of the condition are more likely to recover than those who do not. If spinal cord tissue **death** (necrosis) occurs, the chance of a complete recovery is poor. Most recovery occurs within the first three months. A certain percentage of patients with TM will go on to develop multiple sclerosis.

This man's hand was surgically reattached following a traumatic amputation. *(Custom Medical Stock Photo, Inc. Reproduced by permission.)*

Traumatic amputations

Definition

Traumatic **amputation** is the accidental severing of some or all of a body part. A complete amputation totally detaches a limb or appendage from the rest of the body. In a partial amputation, some soft tissue remains attached to the site.

Description

Trauma is the second leading cause of amputation in the United States. About 30,000 traumatic amputations occur in this country every year. Four of every five traumatic amputation victims are male, and most of them are between the ages of 15–30.

Traumatic amputation most often affects limbs and appendages like the arms, ears, feet, fingers, hands, legs, and nose.

Causes and symptoms

Farm and factory workers have greater-than-average risks of suffering injuries that result in traumatic amputation. Automobile and motorcycle accidents and the use of lawnmowers, saws, and power tools are also common causes of traumatic amputation.

Blood loss may be massive or minimal, depending on the nature of the injury and the site of the amputation. Patients who lose little blood and have less severe injuries sometimes feel more **pain** than patients who bleed heavily and whose injuries are life-threatening.

Diagnosis

When the patient and the amputated part(s) reach the hospital, an Emergency Department physician will assess the probability that the severed tissue can be successfully reattached.

The Mangled Extremity Severity Score (MESS) assigns numerical values to such factors as body temperature, circulation, **numbness**, **paralysis**, tissue health, and the patient's age and general health. This is one of the diagnostic tools used to determine how successful reattachment surgery is apt to be. The total score is doubled if blood supply to the amputated part has been absent or diminished for more than six hours.

A general, emergency, or orthopedic surgeon makes the final determination about whether surgery should be performed. The surgeon also considers the patient's wishes and lifestyle. Additional concerns are how and to what extent the amputation will affect the patient's quality of life and ability to perform everyday activities.

Treatment

First aid or emergency care given immediately after the amputation has a critical impact on both the physicians' ability to salvage and reattach the severed part(s) and the patient's ability to regain feeling and function.

Muscle tissue dies quickly, but a well-preserved part can be successfully reattached as much as 24 hours after the amputation occurs. Tissue that has not been preserved will not survive for more than six hours.

Initial response

The most important steps to take when a traumatic amputation occurs are:

- Contact the nearest emergency services provider, clearly describe what has happened, and follow any instructions given.
- Make sure the victim can breathe; administer CPR if necessary.
- Control bleeding, using direct pressure but minimizing or avoiding contact with blood and other body fluids.
- Patients should not be moved if back, head, leg, or neck injuries are suspected or if motion causes pain. If none are found by the EMT, lie the victim flat, with the feet raised 12 inches above the surface.
- Cover the victim with a coat or blanket to prevent shock.

The injured site should be cleansed with a sterile solution and wrapped in a clean towel or other thick material that will protect the wound from further injury. Tissue that is still attached to the body should not be forced back into place. If it cannot be gently replaced, it should be held in its normal position and supported until additional care is available.

Saving the patient's life is always more important than recovering the amputated part(s). Transporting the patient to a hospital or emergency center should never be delayed until missing pieces are located.

Preserving tissue

No amputated body part is too small to be salvaged. Debris or other contaminating material should be removed, but the tissue should not be allowed to get wet.

An amputated body part should be wrapped in **bandages**, towels, or other clean, protective material and sealed in a plastic bag. Placing the sealed bag in a cooler or in a container that is inside a second container filled with cold water or ice will help prevent tissue deterioration.

KEY TERMS

Phantom pain—Pain, tingling, itching, or numbness in the place where the amputated part used to be.

Prognosis

Possible complications of traumatic amputation include:

- excessive bleeding
- infection
- muscle shortening
- pulmonary embolism.

Improved medical and surgical care and **rehabilitation** have improved the long-term outlook for these patients.

Phantom pain

About 80% of all amputees over the age of four experience **tingling**, **itching**, numbness, or pain in the place where the amputated part used to be. Phantom sensations may begin immediately after the amputation, or they may develop months or years later. They often occur after an injury to the site of the amputation.

These intermittent feelings may:

- occur frequently or only once in a while
- be mild or intense
- last for a few minutes or several hours
- help patients adjust more readily to an artificial limb (prosthesis).

Prevention

The best way to prevent traumatic amputation is to observe common-sense precautions like using seat belts and obeying speed limits and other traffic regulations. It is important to take special precautions when using potentially dangerous equipment and make sure machinery is turned off and disconnected before attempting to service or repair it. Appropriate protective clothing should be worn at all times.

Maureen Haggerty

Traveler's diarrhea

Definition

The occurrence of multiple loose bowel movements in someone traveling to an area outside their usual surroundings (usually from temperate industrialized regions to tropical areas), is known as Traveler's **diarrhea** (TD). The cause is almost always due to a bacterial or viral infection acquired through ingesting contaminated food or water.

Description

It is estimated that anywhere from 20–50% of the 12–20 million travelers going from temperate industrialized countries to the tropics will develop TD. Fortunately, most of these episodes are of short duration. Nevertheless, about 40% of those affected will need to rearrange their schedule, and 20% will be ill enough to remain in bed for some days.

The chance of winding up with TD is directly related to the area one is traveling to; only about 8% of individuals visiting an industrialized country are affected, whereas at least half of those traveling to non-industrialized regions become ill. It is also clearly related to the number of potentially contaminated foods or beverages consumed. Attention to recommended guidelines regarding food safety and sanitation can greatly decrease the risk of infection.

Causes and symptoms

Bacterial infections are the most common cause of the illness. Viruses and occasional parasites also can be the cause. As for the bacteria involved, toxin producing types of *E. coli* (called enterotoxigenic) account for approximately 40–60% of cases, with *Campylobacter* and *Shigella* each reported in at least 10% of cases. In some studies, *Campylobacter* has accounted for almost half of the attacks, especially during cooler seasons of the year. The cause can vary depending on several factors, including the season and country visited. More than one organism can be found in 15–30% of cases, while none is identified in up to 40% of cases worldwide.

Rotaviruses and a parvovirus called Norwalk agent also are responsible for TD. *Giardia* is probably the most common parasite identified, though amoebas (*Entamoeba histolytica*), *Cryptosporidium*, and *Cyclospora* are being found with increasing frequency. Amazingly, research released in 2003 found that those living in undeveloped countries with poor sanitation and high incidence of diarrheal disease also have the lowest incidence of colorectal **cancer**. It appears that an enterotoxin secreted from multiple bacteria leads to **colon cancer** resistance.

Younger age groups, particularly students, are at greatest risk, probably because of where and what they eat. Individuals over 55 years of age, persons staying with relatives, or business travelers are at lower risk. Foods with the highest chance of transmitting disease are uncooked vegetables, unpeeled fruits, meat, and seafood. Tap water and even ice can be dangerous unless one is sure of the source.

Symptoms usually start within a few days after arrival, but can be delayed for as long as two weeks. Illness lasts an average of 3 to 5 days, but is sometimes longer. Cramping abdominal **pain**, lack of appetite, and diarrhea are the main complaints. In approximately 10% of patients, diarrhea turns bloody. **Fever** develops in about half of them. The presence of bloody bowel movements and fever usually indicates a more severe form of illness and makes *Shigella* a more likely cause. Medications that decrease the motility or contractions of the intestine, such as loperamide (Imodium) or diphenoxylate (Lomotil), should not be used when fever or bleeding occur.

Complications

Diarrhea varies from a few loose stools per day to 10 or more. **Dehydration** and changes in the normal blood pH (acid-base balance) are the main dangers associated with TD. Signs of dehydration can be hard to notice, but increasing thirst, **dry mouth**, weakness or lightheadedness (particularly if worsening while standing), or a darkening/decrease in urination are suggestive. Severe dehydration and changes in the body's chemistry can lead to kidney failure and become life-threatening.

Another potential complication is "toxic megacolon," in which the colon gradually stretches and its wall thins to the point where it can tear. The presence of a hole in the intestine leads to **peritonitis** and is fatal unless quickly recognized and treated.

Other complications related to TD can involve the nervous system, skin, blood, or kidneys.

Diagnosis

The occurrence of diarrhea in an individual while traveling is very suggestive of TD. Although there are other possible causes, these are less likely. In most instances, the specific organism responsible for the symptoms does not need to be identified, and the majority of patients need only rest and treatment to avoid potential complications.

When patients develop fever or bloody diarrhea, the illness is more serious and a specific diagnosis is needed. In those cases, or when symptoms last longer than expected, stool samples are obtained to identify the organism.

For this purpose, laboratories can either try to grow (culture) the organism, or identify it with high-powered microscopes (electron microscopy) or with the use of special tests or stains. These can show parasites such as *Giardia, Amoeba, Cryptosporidium* and others in freshly obtained stool specimens. New techniques that involve identification of DNA (the characteristic material that controls reproduction and is unique for all individuals) of the various organisms, also can be used in special circumstances.

Treatment

The best treatment of TD is prevention; however, once disease occurs, therapy is aimed at preventing or reducing dehydration, and using **antibiotics** when needed. Fortunately, severe dehydration is unusual in patients with TD, but any fluid losses should be treated early with either fruit juices and "clear fluids" such as tea or broth, or with the recommended Oral Rehydration Solutions (ORS) suggested by the World Health Organization (WHO). Persons traveling to known areas of infection should consult with their physician prior to departure and obtain appropriate instructions. For example, it may be advised to take along pre-prepared packets of ORS designed for easy mixing or commercial preparations such as Pedialyte, Ceralyte, Ricelyte, etc.

When nothing else is available, the following WHO recipe can be made up from household items and taken in small frequent sips;

- table salt: 1-3/4 teaspoon
- baking powder: 1 teaspoon
- orange juice: 1 cup
- water: 1 quart or liter

A debate has occurred in the medical community over the amount of salt (**sodium**) in the WHO preparations; some physicians feel that the content is too much for use by well-nourished persons in developed countries. Therefore these preparations should not be used for extended periods of time without consulting a physician.

Pepto-Bismol (bismuth subsalicylate preparation) is effective in both preventing and treating TD. For treatment once symptoms begin, the drug must be taken more frequently than when used for prevention. Bismuth subsalicylate preparation (1 oz of liquid or two 262.5-mg tablets every 30 minutes for eight doses) has been shown to decrease the number of bowel movements and shorten the length of illness. However, there is some concern about the large doses of bismuth in patients with **kidney disease**; therefore patients should check with physicians before starting this or any other therapy. Patients should be aware that bismuth can turn bowel movements black in color.

A new drug called rifamixin (Normix) for treating traveler's diarrhea was approved by the U.S. Food and Drug Administration (FDA) in 2010. Medications designed to decrease intestinal motility and contractions such as loperamide (Imodium), diphenoxylate (Lomotil), or others are safest when used by those without fever or bloody bowel movements. The presence of either of these symptoms indicates a more severe form of **colitis**.

Antibiotics are usually not prescribed, because most cases of TD rapidly improve with minimal treatment. For patients in whom symptoms are especially severe (4 or more stools per day or the onset of bloody diarrhea or fever), or those with compromised immune systems, antibiotics are indicated. Individuals with less severe attacks can be treated with either antimotility medications or bismuth subsalicylate.

Choice of an antibiotic should ideally be tailored to the most likely organism and then adjusted according to results of stool cultures. Trimethoprim-sulfamethoxazole (Bactrim) or ciprofloxacin (Cipro) are the antibiotics most often prescribed, but others are also used. The type and duration of treatment continues to be revised, and it is therefore extremely important that patients check with a physician prior to beginning treatment. In many instances, an antibiotic can be combined with an anti-motility agent to provide the quickest relief.

Prognosis

Up to 1% of patients with TD will become sick enough to require hospitalization, and 3% will continue to experience diarrhea for at least one month. The majority of patients rapidly recover with minimal therapy. Some will suffer symptoms for even longer. The small number who continue to suffer symptoms will need careful evaluation to rule out the many causes of chronic diarrhea (such as lactase deficiency, **irritable**

KEY TERMS

Oral Rehydration Solution (ORS)—A liquid preparation developed by the World Health Organization that can decrease fluid loss in persons with diarrhea. Originally developed to be prepared with materials available in the home, commercial preparations have recently come into use.

bowel syndrome, parasites, etc.). It is unusual for diarrhea caused by bacteria to last over two weeks; therefore, more prolonged diarrhea indicates a non-bacterial cause.

Prevention

The best means of prevention is avoiding foods, beverages, and food handling practices that lead to infection with the organisms that cause TD. Drinking bottled water and using bottled water for brushing teeth, eating fruits that the traveler peels on his or her own, and eating well-cooked, hot foods can help prevent illness.

One effective means to prevent TD is liquid Pepto-Bismol; this bismuth-containing compound has been shown to be very effective in reducing the incidence of TD. Tablets are now available, which are easier to carry. Two tablets four times a day is recommended, but use should not go beyond three weeks.

Antibiotics can also prevent TD, but their use is controversial, unless it is absolutely necessary to avoid infection (such as someone on an important business trip or who has a weakened immune system). There is the tendency for bacteria to become resistant to these medications if used excessively; and these drugs have side effects that can be worse than the effects of TD. The benefits and risks of antibiotic treatment should be carefully weighed.

Tremors

Definition

Tremor is an unintentional (involuntary), rhythmical alternating movement that may affect the muscles of any part of the body. Tremor is caused by the rapid alternating contraction and relaxation of muscles and is a common symptom of diseases of the nervous system (neurologic disease).

Description

Occasional tremor is felt by almost everyone, usually as a result of fear or excitement. However, uncontrollable tremor or shaking is a common symptom of disorders that destroy nerve tissue, such as Parkinson's disease or **multiple sclerosis**. Tremor may also occur after **stroke** or **head injury**. Other tremors appear without any underlying illness.

Causes and symptoms

Tremor may be a symptom of an underlying disease, and it may be caused by drugs. It may also exist as the only symptom (essential tremor).

Underlying disease

Some types of tremor are signs of an underlying condition. About a million and a half Americans have Parkinson's disease, a disease that destroys nerve cells. Severe shaking is the most apparent symptom of Parkinson's disease. This coarse tremor features four to five muscle movements per second. The shaking is evident at rest but declines or disappears during movement.

Other disorders that cause tremor are multiple sclerosis, Wilson's disease, **mercury poisoning**, thyrotoxicosis, and **liver encephalopathy**.

A tremor that gets worse during body movement is called an "intention tremor." This type of tremor is a sign that something is amiss in the cerebellum, a region of the brain concerned chiefly with movement, balance and coordination.

Essential tremor

Many people have what is called "essential tremor," in which the tremor is the only symptom. This type of shaking affects between three and four million Americans.

The cause of essential tremor is not known, although it is an inherited problem in more than half of all cases. The genetic condition has an autosomal dominant inheritance pattern, which means that any child of an affected parent will have a 50% chance of developing the condition.

Essential tremor most often appears when the hands are being used, whereas a person with Parkinson's disease will most often have a tremor while walking or while the hands are resting. People with essential tremor will usually have shaking head and hands, but the tremor may involve other parts of the body. The shaking often begins in the dominant hand and may spread to the other hand, interfering with eating and writing. Some people also develop a quavering voice.

Essential tremor affects men and women equally. The shaking often appears at about age 45, although the disorder may actually begin in adolescence or early adulthood. Essential tremor that begins very late in life is sometimes called "senile tremor."

Drugs and tremor

Several different classes of drugs can cause tremor as a side effect. These drugs include amphetamines, **antidepressant drugs**, **antipsychotic drugs**, **caffeine**, and lithium. Tremor also may be a sign of withdrawal from alcohol or street drugs.

Diagnosis

Close attention to where and how the tremor appears can help provide a correct diagnosis of the cause of the shaking. The source of the tremor can be diagnosed when the underlying condition is found. Diagnostic techniques that make images of the brain, such as computed tomography scan (CT scan) or **magnetic resonance imaging** (MRI), may help form a diagnosis of multiple sclerosis or other tremor caused by disorders of the central nervous system. Blood tests can rule out such metabolic causes as thyroid disease. A family history can help determine whether the tremor is inherited.

Treatment

Neither tremor nor most of its underlying causes can be cured. Most people with essential tremor respond to drug treatment, which may include propranolol, primidone, or a benzodiazepine. People with Parkinson's disease may respond to levodopa or other **antiparkinson drugs**.

Research has shown that about 70% of patients treated with botulinum toxin A (Botox) have some improvement in tremor of the head, hand, and voice. Botulinum is derived from the bacterium *Clostridium botulinum*. This bacterium causes **botulism**, a form of **food poisoning**. It is poisonous because it weakens muscles. A very weak solution of the toxin is used in cases of tremor and **paralysis** to force the muscles to relax. However, some patients experience unpleasant side effects with this drug and cannot tolerate effective doses. For other patients, the drug becomes less effective over time. About half of patients don't get any relief of tremor from medications.

Tremor control therapy

Tremor control therapy is a type of treatment using mild electrical pulses to stimulate the brain. These pulses block the brain signals that trigger tremor. In this technique, the surgeon implants an electrode into a large oval area of gray matter within the brain that acts as a relay center for nerve impulses and is involved in generating movement (thalamus). The electrode is attached to an insulated wire that runs through the brain and exits the skull where it is attached to an extension wire. The extension is connected to a generator similar to a heart pacemaker. The generator is implanted under the skin in the chest, and the extension is tunneled under the skin from the skull to the generator. The patient can control his or her tremor by turning the generator on with a hand-held magnet to deliver an electronic pulse to the brain.

Some patients experience complete relief with this technique, but for others it is of no benefit at all. About 5% of patients experience complications from the surgical procedure, including bleeding in the brain. The procedure causes some discomfort, because patients must be awake while the implant is placed. Batteries must be replaced by surgical procedure every three to five years.

Other surgical treatments

A patient with extremely disabling tremor may find relief with a surgical technique called thalamotomy, in which the surgeon destroys part of the thalamus. However, the procedure is complicated by **numbness**, balance problems, or speech problems in a significant number of cases.

KEY TERMS

Computed tomography (CT) scan—An imaging technique in which cross-sectional x rays of the body are compiled to create a three-dimensional image of the body's internal structures.

Essential tremor—An uncontrollable (involuntary) shaking of the hands, head, and face. Also called familial tremor because it is sometimes inherited; it can begin in the teens or in middle age. The exact cause is not known.

Fetal tissue transplantation—A method of treating Parkinson's and other neurological diseases by grafting brain cells from human fetuses onto the affected area of the human brain. Human adults cannot grow new brain cells but developing fetuses can. Grafting fetal tissue stimulates the growth of new brain cells in affected adult brains.

Intention tremor—A rhythmic purposeless shaking of the muscles that begins with purposeful (voluntary) movement. This tremor does not affect muscles that are resting.

Liver encephalopathy—A condition in which the brain is affected by a buildup of toxic substances that would normally be removed by the liver. The condition occurs when the liver is too severely damaged to cleanse the blood effectively.

Multiple sclerosis—A degenerative nervous system disorder in which the protective covering of the nerves in the brain are damaged, leading to tremor and paralysis.

Magnetic resonance imaging (MRI)—An imaging technique that uses a large circular magnet and radio waves to generate signals from atoms in the body. These signals are used to construct images of internal structures.

Pallidotomy—A surgical procedure that destroys a small part of a tiny structure within the brain called the globus pallidus internus. This structure is part of the basal ganglia, a part of the brain involved in the control of willed (voluntary) movement of the muscles.

Parkinson's disease—A slowly progressive disease that destroys nerve cells. Parkinson's is characterized by shaking in resting muscles, a stooping posture, slurred speech, muscular stiffness, and weakness.

Thalamotomy—A surgical procedure that destroys part of a large oval area of gray matter within the brain that acts as a relay center for nerve impulses. The thalamus is an essential part of the nerve pathway that controls intentional movement. By destroying tissue at a particular spot on the thalamus, the surgeon can interrupt the nerve signals that cause tremor.

Thalamus—A large oval area of gray matter within the brain that relays nerve impulses from the basal ganglia to the cerebellum, both parts of the brain that control and regulate muscle movement.

Thyrotoxicosis—An excess of thyroid hormones in the blood, causing a variety of symptoms that include rapid heart beat, sweating, anxiety, and tremor.

Tremor control therapy—A method for controlling tremor by self-administered shocks to the part of the brain that controls intentional movement (thalamus). An electrode attached to an insulated lead wire is implanted in the brain; the battery power source is implanted under the skin of the chest, and an extension wire is tunneled under the skin to connect the battery to the lead. The patient turns on the power source to deliver the electrical impulse and interrupt the tremor.

Wilson's disease—An inborn defect of copper metabolism in which free copper may be deposited in a variety of areas of the body. Deposits in the brain can cause tremor and other symptoms of Parkinson's disease.

Pallidotomy is another type of surgical procedure sometimes used to decrease tremors from Parkinson's disease. In this technique, the surgeon destroys part of a small structure within the brain called the globus pallidus internus. The globus is part of the basal ganglia, another part of the brain that helps control movement. This surgical technique also carries the risk of disabling permanent side effects.

Fetal tissue transplantation (also called a nigral implant) is a controversial experimental method to treat Parkinson's disease symptoms. This method implants fetal brain tissue into the patient's brain to replace malfunctioning nerves. Unresolved issues include how to harvest the fetal tissue and the moral implications behind using such tissue, the danger of tissue rejection, and how much tissue may be required.

Although initial studies using this technique looked promising, there has been difficulty in consistently reproducing positive results.

Small amounts of alcohol may temporarily (sometimes dramatically) ease the shaking. Some experts recommend a small amount of alcohol (especially before dinner). The possible benefits, of course, must be weighed against the risks of alcohol **abuse**.

Prognosis

Essential tremor and the tremor caused by neurologic disease (including Parkinson's disease) slowly get worse and can interfere with a person's daily life. While the condition is not life-threatening, it can severely disrupt a person's everyday experiences.

Prevention

Essential tremor and tremor caused by a disease of the central nervous system cannot be prevented. Avoiding use of stimulant drugs such as caffeine and amphetamines can prevent tremor that occurs as a side effect of drug use.

Carol A. Turkington

Trench fever

Definition

Trench **fever** is a bacterial infection that causes repeated cycles of high fever.

Description

The term trench fever refers to the crowded conditions in which troops fought in during World War I and World War II. Because the causative bacteria are passed among humans through contact with body lice, overcrowding, and conditions which interfere with good hygiene (including regular washing of clothing) soldiers were predispose to this disease. Currently, homeless people in the United States are sometimes diagnosed with this illness. The bacteria are sometimes passed through the bite of an infected tick. This can cause the illness in people who participate in outdoor activity and encounter ticks in that particular area.

Causes and symptoms

Two different bacteria can cause trench fever: *Bartonella quintana* and *Bartonella henselae*.*B. quintana* is carried by body lice; *B. henselae* is carried by ticks.

Infection with *B. quintana* occurs when an infected louse defecates while feeding on a human. When the person scratches, the feces (which are full of bacteria) are rubbed into the tiny wound. Infection with *B. henselae* occurs when an infected tick **bites** a human, passing the bacteria along through the tiny bite wound.

Symptoms of trench fever begin about 2 weeks to a month after exposure to the bacteria. Sudden fever, loss of energy, **dizziness**, **headache**, weight loss, skin rash, severe muscle and bone **pain** can occur. Pain is particularly severe in the shins, leading to the nickname "shin bone fever." The fever can reach 105°F (40.5°C) and stays high for five to six days at a time. The temperature then drops, and stays down for several days, usually recurring in five- to six-day cycles. An individual may experience as many as eight cycles of fever with the illness.

Diagnosis

Diagnosis is usually made on the basis of the patient's symptoms, and on knowledge of the conditions in which the patient lives. A blood sample can be drawn and bacteria in the sample are allowed to grow. Identification is made by looking at the number of bacteria that may be present on a glass slide seen under the lens of a microscope. However, this technique can take up to four weeks, because this type of bacterium grows very slowly. By this time, the practitioner has often decided to treat the patient anyway.

Treatment

Erythromycin and azithromycin are both used to treat trench fever. Four weeks of treatment are usually necessary. Inadequate treatment often results in a relapse. In fact, relapses have been reported to occur as long as 10 years after the first episode.

Prognosis

Prognosis for patients with trench fever is excellent. Recovery may take a couple of months. Without treatment, there is always a risk of recurrence, even years after the original illness.

Prevention

Prevention involves good hygiene and decent living conditions. When this is impossible, insecticide dusting powders are available to apply to clothing. Avoidance of areas known to harbor ticks or the use of insect repellents is necessary to avoid the type of infection passed by ticks.

Trichinella spiralis infectio *see* **Trichinosis**

Trichiniasis *see* **Trichinosis**

Trichinosis

Definition

Trichinosis is a disease caused by a roundworm (nematode) called *Trichinella spiralis*. An individual worm of this species is called a trichina, from the Greek word meaning "hairlike." Trichinae can be readily avoided by proper handling and cooking of certain meats, particularly pork products.

Description

The life cycle of *T. spiralis* includes several different stages. The adult trichina lives in the intestinal lining of such meat-eating animals as swine, bears, walrus, and rodents. After mating, the male worm dies while the female goes on to produce the offspring.

Roundworms have a stage of development called the embryonic stage, which in many species occurs after birth. In trichinae, however, this embryonic stage occurs within the uterus of the female, so the offspring that are ultimately discharged into the host's intestinal lining are in the larval second stage of life. These larvae–about 1500 from each female worm–travel through the circulatory system to the heart, then through the blood vessels leading to striated muscle (the muscle of the skeletal system and the heart). Most larvae that cannot find suitable locations in striated muscle will die.

Those larvae that reach striated muscle will grow to a length of about one millimeter, coil themselves, and enclose themselves within a protective wall called a cyst. This process is referred to as encysting. The worms in the cysts can live for up to ten years in this form.

A pig that has been infected with *T. spiralis*, then, has thousands of cysts lying dormant within its muscles–the very muscles that humans look forward to consuming in the form of pork chops, ham, barbecued ribs, etc. When humans sit down to a delicious meal of undercooked, trichina-infected pig dinner, they are ingesting *T. spiralis* cysts. The cyst walls are broken down by the usual process of food digestion in the stomach, allowing the larvae to escape into the new host's intestines. There the larvae mature to become adult worms, capable of producing a new crop of larvae. When these new larvae hatch, they begin their migration throughout the human host's bloodstream to his or her muscles, where they live for a short while before encysting.

Causes and symptoms

Human hosts who eat meat infested with trichinae may experience symptoms in varying degrees. If the meat ingested has only a few cysts, then the human host's load of parasites (worm burden) is said to be relatively small, and symptoms will be moderate. In fact, many trichinosis infections are subclinical, which means that the symptoms are so mild that the infection remains undiagnosed. In a host with a greater worm burden, the initial symptoms will be caused by the presence of the adult worms in the intestine. These symptoms usually include **fever**, **diarrhea**, abdominal **pain**, and perhaps **vomiting**. The symptoms begin about one to two days after eating the contaminated meat, and may last for a week or so.

When the larvae begin their migration through the blood vessels, the host will begin to experience symptoms that affect the whole body (systemic symptoms), such as fever; swelling of the face and the area around the eyes; rash; bleeding into the nail beds, retina, and whites of the eyes; and **cough**. In very severe cases of trichinosis, inflammation of the heart muscle (**myocarditis**), lungs (pneumonitis), or brain (**encephalitis**) may occur. These symptoms can lead to the few deaths caused by trichinosis.

The larvae begin to burrow into the host's muscles and form cysts within two to three weeks of the initial

infection. This encysting produces signs of muscle inflammation (**myositis**) including swelling of the affected muscle groups, pain, and weakness. The most frequently affected muscles are the muscles outside the eye (extraocular muscles) that control eye movements; the muscles of the jaw, neck, and upper arm (biceps muscle); the muscles of the lower back (lumbar region); and the diaphragm, which is the muscle that separates the abdominal and chest cavities and aids in breathing.

The symptoms of trichinosis are at their most severe at about three weeks after infection, and decrease very slowly in their severity. Recovery is extremely gradual, and symptoms may last for as long as three months. **Fatigue** and muscle pain (myalgia) may take several more months to subside.

Diagnosis

An initial diagnosis of trichinosis relies heavily on the presence of its classic symptoms–swelling around the eyes, muscle inflammation, fever, and high levels of a certain type of white blood cell (eosinophils)–coupled with the patient's history. If the patient reports having eaten undercooked meat from an animal known to be a potential carrier of trichinosis, the doctor may order a muscle biopsy to confirm the diagnosis. By the third or fourth week of infection, muscle biopsies usually indicate the presence of larvae. Stool tests rarely reveal adult worms, although larvae can sometimes be found in blood or duodenal washings after the second week of infection. The blood test that is the most specific for trichinosis is the bentonite flocculation (BF) test.

T. spiralis can infect a number of different animal species used for food. The most common food culprit in the United States has been pork sausage, while outbreaks in Europe have caused by wild boar and horse meat. Outbreaks of trichinosis in Asia and Africa have been traced to dog meat, and outbreaks in Northern Canada have resulted from consumption of walrus and bear meat.

Treatment

Supportive care

Treatment of trichinosis is primarily aimed at decreasing the severity of the symptoms. Symptomatic relief includes bed rest and medications to relieve fever and muscle pain. The medications most commonly given are **aspirin** and **nonsteroidal anti-inflammatory drugs** (NSAIDs). **Steroids** such as prednisone (Deltasone, Meticorten) are reserved for the most severe cases of muscle inflammation, or for complicated cases that include myocarditis.

KEY TERMS

Anthelminthic—A type of medication that is given to destroy or eliminate parasitic worms.

Cyst—In the life cycle of the round worm, a protective, walled-off capsule in which the larvae lie dormant.

Embryonic—In the life cycle of the round worm, a very early life stage occurring within the uterus of the female round worm.

Host—The animal within which a parasite lives, and from which the parasite receives its nutrition.

Inflammation—A reaction within the body to an invader (virus, bacteria, fungus, worm, etc.) or to tissue injury. The classic signs of inflammation include redness, heat, pain, and loss of function.

Larva—In the life cycle of the round worm, the second stage of life, sometimes considered the "adolescent" stage.

Nematode—A type of roundworm with a long, unsegmented body, usually parasitic on animals or plants.

Striated muscle—Also known as striped muscle; it includes muscles of the skeletal system and of the heart.

Trichina—An individual example of *Trichinella spiralis*.

Anthelminthic medications

In addition to medications for pain relief, trichinosis can be treated with drugs that are called anti-worm medications or anthelminthics. Two related anti-worm medications, mebendazole (Vermox) and thiabendazole (Mintezol), have been reported to be effective against intestinal larvae, but not against larvae encysted in the muscles. In particular, thiabendazole has worked best when given to patients who knew within 24 hours that they had eaten infested meat. Thiabendazole has, however, anti-inflammatory properties that can relieve some of the pain during the muscle stage of trichinosis.

Prognosis

The prognosis for recovery from trichinosis is generally good. Most people with the disease are unaware that they have even been infected. It is estimated that between 150,000 and 300,00 people in the United States become infected yearly, so that at any given time, 1.5 million people have *T. spiralis* infections. Most of these

people have such light cases that trichinosis is never identified. Worm burden is measured in larvae per gram of muscle tissue; people with 10 or fewer larvae per gram of muscle tissue usually have no significant symptoms. When the number climbs to 100 larvae per gram of muscle tissue, the symptoms become noticeable. People with over 1000 larvae per gram of muscle tissue are usually extremely ill, and often die. The mortality rate of trichinosis is about 1%.

Prevention

Prevention of trichinosis is relatively simple. Swine should be fed only grain or cooked garbage because uncooked garbage may contain contaminated pork scraps. Meat from animals prone to trichinosis infection should be cooked or smoked thoroughly until it is no longer pink. Freezing meat at an adequately low temperature (5°F/–15°C for three weeks) can kill most encysted larvae, except for species which infect such arctic mammals as walrus or bear.

Trichomonas vaginalis infection *see* **Trichomoniasis**

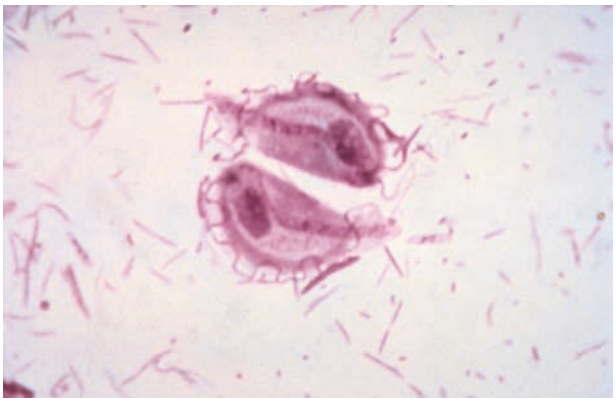
Trichomoniasis

Definition

Trichomoniasis refers to an infection of the genital and urinary tract. It is the most common sexually transmitted disease, affecting about 120 million women worldwide each year.

Description

Trichomoniasis is caused by a protozoan (the smallest, single-celled members of the animal kingdom). *Trichomonas vaginalis* is passed almost 100% of the time through sexual contact. Trichomoniasis is primarily an infection of women's vaginal and urinary tracts. A woman is most susceptible to infection just after having completed her menstrual period. Men may carry the organism unknowingly, since infection in men may cause mild or no symptoms.



A close-up image of *Trichomonas vaginalis*, the parasite that causes vaginitis in humans. *(Custom Medical Stock Photo, Inc. Reproduced by permission.)*

Causes and symptoms

Because trichomoniasis is a sexually transmitted disease, it occurs more often in individuals who have multiple sexual partners. The protozoan is passed to an individual by contact within the body fluids of an infected sexual partner. It often occurs simultaneously with other **sexually transmitted diseases**, especially **gonorrhea**.

In women, the symptoms of trichomoniasis include an unpleasant vaginal odor, and a heavy, frothy, yellow discharge from the vagina. The genital area (vulva) is often very itchy, and there is frequently **pain** with urination or with sexual intercourse. The labia (lips) of the vagina, the vagina itself, and the cervix (the narrowed, lowest segment of the uterus which extends into the upper part of the vagina) will be bright red and irritated.

In men, there are usually no symptoms at all. Occasionally, a man will notice a small amount of yellowish discharge from his penis, usually first thing in the morning. There may be some inflammation of the urethra, or **urethritis**, which produces mild discomfort while urinating.

The use of **antibiotics** is a contributing factor to recurrent trichomoniasis in some women because antibiotics affect the balance of bacteria in the vagina, allowing such organisms as *T. vaginalis* to multiply more rapidly.

Diagnosis

Diagnosis is easily made by taking a sample of the discharge from the women's vagina, or from the opening of the man's penis. The sample is put on a slide, and viewed under a microscope. The protozoa, which are able to move about, are easily viewed.

KEY TERMS

Metronidazole—An anti-infective agent regarded as the best available drug for treating trichomoniasis. It is sold under the trade names Flagyl and MetroGel.

Protozoan—A one-celled organism belonging to the simplest phylum of the animal kingdom. Trichomoniasis is caused by a protozoan.

Urethritis—Inflammation of the urethra, which is the canal that carries urine from the bladder to the outside of the body.

Trichomoniasis tends to be underdiagnosed in men because of the relative mildness of symptoms in men and insufficiently sensitive diagnostic tests. The recent introduction of DNA amplification, however, indicates that the incidence of trichomoniasis in men is much higher than was previously thought.

Treatment

The usual treatment is a single large dose of metronidazole, or split doses over the course of a week. Sexual partners of an infected individual must all be treated, to prevent the infection being passed back and forth.

Women who are taking antibiotics for other illnesses should speak to their health care provider about the possibile effects of the medication(s) on the balance of organisms in their vagina.

As of late 2003, the number of cases of metronidazole-resistant trichomoniasis appears to be increasing rapidly. Some success has been reported with the broad-spectrum anti-parasitic drug nitazoxanide, but further research needs to be done. A group of researchers in Thailand is currently investigating the effectiveness of a group of drugs known as bisquaternary quinolinium salt compounds in treating trichomoniasis.

Alternative treatment

Cure of trichomoniasis may be difficult to achieve with alternative treatments. Some practitioners suggest eliminating sweets and carbohydrates from the diet and supplementing with **antioxidants**, including **vitamins** A, C, and E, and zinc. Naturopaths may recommend treatment with two douches (a wash used inside the vagina), alternating one in the morning and one at bedtime. One douche contains the herbs calendula (*Calendula officinalis*), goldenseal (*Hydrastis canadensis*), and **echinacea** (*Echinacea* spp.); the other douche contains plain yogurt. The herbal douche helps to kill the protozoa, while the yogurt reestablishes healthy flora in the vagina. Another herbal remedy that is sometimes used is tea tree oil. Acidifying the vagina by douching with boric acid or vinegar may also be useful.

Prognosis

Prognosis is excellent with appropriate treatment of the patient and all sexual partners. Without treatment, the infection can smolder on for a very long time, and can be passed to all sexual partners.

Prevention

All sexually transmitted diseases can be prevented by using adequate protection during sexual intercourse. Effective forms of protection include male and female **condoms**.

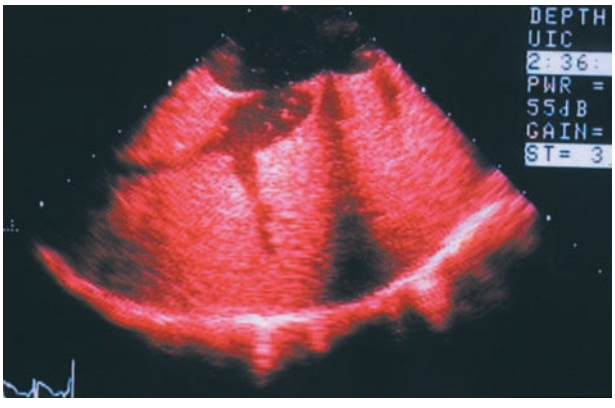
Tricuspid valve insufficiency

Definition

Tricuspid valve insufficiency occurs when a tricuspid valve does not close tightly enough to prevent leakage. This condition is also called tricuspid valve regurgitation and tricuspid incompetence.

Description

The tricuspid valve is located between the right atrium and the right ventricle of the heart. When the right ventricle contracts, it is supposed to pump blood forward into the lungs. If the tricuspid valve does not close tightly, some of that blood leaks back into the right atrium. When the atrium receives its usual quantity of blood from veins leading to the heart, plus the leaking blood, the pressure inside the atrium increases. This higher pressure creates resistance to the flow of blood in the veins that enter the atrium from the body. In addition, this increase in pressure causes the right atrium to enlarge over time. Congestion from fluid buildup occurs, particularly in the liver and legs.



This echocardiogram of the heart shows tricuspid valve insufficiency. *(Custom Medical Stock Photo, Inc. Reproduced by permission.)*

KEY TERMS

Atrial fibrillation—A rapid, uncoordinated quivering of the upper chamber of the heart.

Atrium—The upper chamber of the heart.

Pulmonary valve—The valve at the opening from the right ventricle to the artery that leads to the lungs.

Causes and symptoms

If a person has serious lung disease or a narrowing of the pulmonary valve, the right ventricle must pump harder to force the blood through the pulmonary valve. In order to pump harder, the right ventricle enlarges and the valve opening stretches, causing the valve to leak.

Tricuspid valve insufficiency usually produces such vague symptoms, as general weakness and **fatigue**. As the conditions worsens, a person experiences **pain** in the upper right part of the abdomen, caused by a congested and enlarged liver. The legs may also swell (**edema**).

An enlarged right atrium can cause **atrial fibrillation** (the atria flutters, rather than pumping in a regular rhythm) and severe tricuspid regurgitation of blood, which can eventually lead to congestive **heart failure**.

Diagnosis

A leaky valve can be heard with a stethoscope; the sound is called a heart murmur. Additional support for diagnosing tricuspid valve insufficiency comes from a medical history, physical exam, and **chest x ray**. Further testing with **echocardiography**, to show an image of the leakage and its severity, is the most helpful diagnostic test for this condition.

Treatment

Tricuspid valve insufficiency itself usually does not require treatment, since a tiny leakage occurs in most normal people. In certain cases, however, if there is underlying pulmonary valve disease or lung disease, those conditions should be treated.

If irregular heart rhythms or heart failure are present, they are usually treated independently of the valve insufficiency.

Since a person with known tricuspid valve insufficiency is at risk for infections of the heart, **antibiotics**

should be taken before and after oral or dental surgery, or urologic procedures.

Prognosis

Tricuspid valve insufficiency is not usually considered to be serious. If it is the result of other cardiopulmonary disease, the extent of those conditions effect the prognosis.

Prevention

In general, tricuspid valve insufficiency cannot be prevented.

Tricuspid valve stenosis

Definition

Tricuspid valve stenosis is a narrowing or stiffening of the opening in the valve. This stenosis causes increased resistance to blood flow through the valve.

Description

The tricuspid valve is located between the right atrium and the right ventricle of the heart. It is the largest of the four valves in the heart. When the tricuspid valve is narrowed or stiffened, it decreases the amount of blood that can flow through it. This decrease raises the pressure in the right atrium and causes the atrium to enlarge. It also causes the right ventricle to shrink, and lowers the cardiac output.

Causes and symptoms

Tricuspid valve stenosis is most often the result of **rheumatic fever**. On rare occasions, it is caused by a tumor or disease of the connective tissue. The rarest cause is a birth defect.

A person with tricuspid valve stenosis may experience generalized weakness and **fatigue**. Many people have **palpitations** and can feel fluttering in their neck. Over time, there may be **pain** in the upper right abdomen, due to increased congestion and enlargement of the liver.

KEY TERMS

Rheumatic fever—An inflammatory illness that can follow strep throat, and could cause heart damage.

Diagnosis

The noise produced by blood trying to flow through a stenotic valve can be heard with a stethoscope, and is referred to as a murmur. An x ray of the chest will show the right atrium to be enlarged. Further support for this diagnosis is found on an echocardiogram of the heart, which will show an image of the stenotic valve and measure its severity.

Treatment

Tricuspid valve stenosis itself usually doesn't require treatment. However, if there is damage to other valves in the heart as well, then surgical repair or replacement must be considered.

Since a person with known tricuspid valve stenosis is at risk for infections of the heart, **antibiotics** should be taken before and after oral or dental surgery, or urologic procedures.

Prognosis

Mild tricuspid valve stenosis is not usually considered cause for surgery. The decision to repair or replace the tricuspid valve is often based on the health of the aortic and mitral valves, rather than on the severity of stenosis in the tricuspid valve.

Prevention

Rheumatic **fever**, the usual cause of tricuspid valve stenosis, has almost disappeared in North America and western Europe. Therefore, the number of people who acquired this condition in childhood will decline over time.

Tricyclic antidepressants *see* **Antidepressants, tricyclic**

Trigeminal neuralgia

Definition

Trigeminal **neuralgia** is a disorder of the trigeminal nerve (the fifth cranial nerve) that causes episodes of sharp, stabbing **pain** in the cheek, lips, gums, or chin on one side of the face.

Description

The trigeminal nerve, which is divided into three branches, is responsible for chewing, for producing saliva and tears, and for sending facial sensations to the brain. When this nerve breaks down for some reason, it can trigger brief but agonizing sizzles of pain on one side of the face.

This condition is unusual in those under age 50 and more often occurs after 70. Women are three times more likely to have the condition than are men. When trigeminal neuralgia does occur in younger people, it is often associated with **multiple sclerosis**.

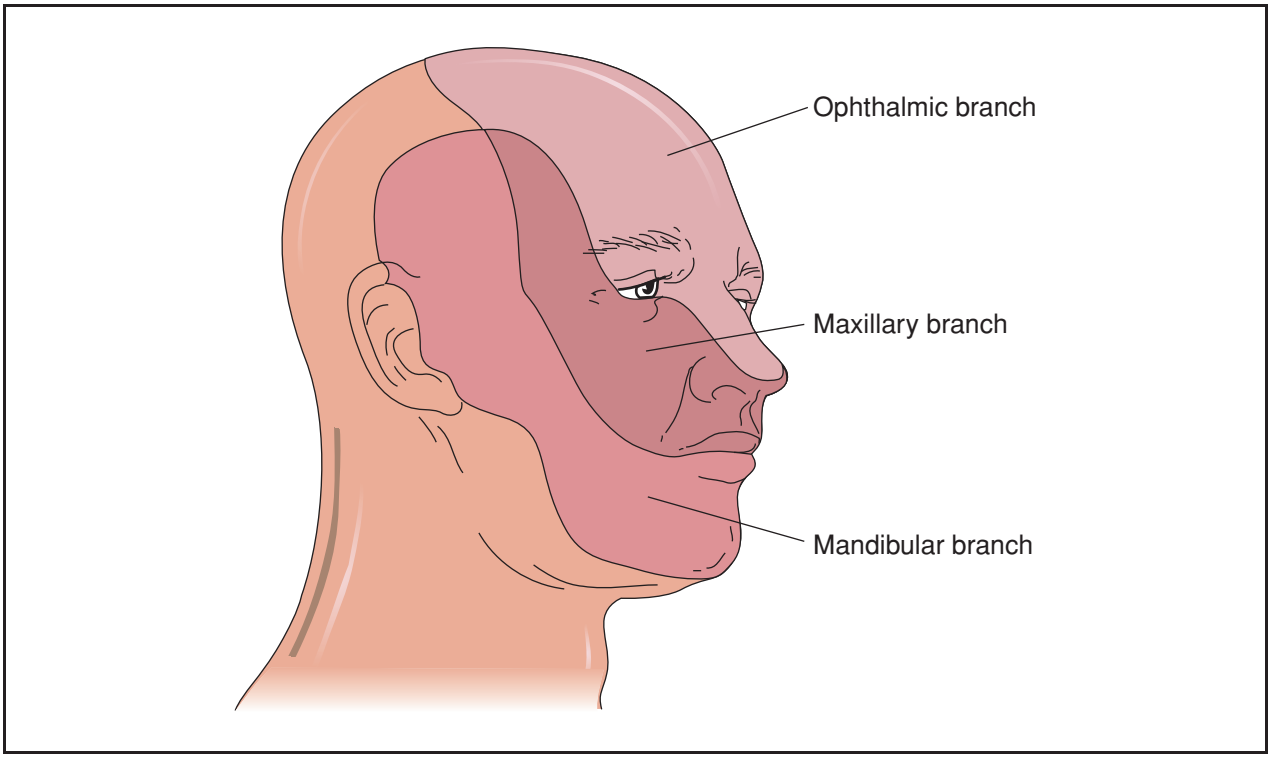
The pain, while brief, is so severe that the sufferer often can't do anything else while the attack lasts. People with this pain often wince or twitch, which is where trigeminal neuralgia gets its French nickname *tic douloureux*, meaning "painful twitch."

Causes and symptoms

The origin of trigeminal neuralgia is not certain, but scientists believe it may be caused by degeneration, pressure, or irritation of the trigeminal nerve. Some doctors believe the pain may be triggered by pressure from a nearby abnormally-formed artery lying too close to the nerve.

Any part of the three branches of the trigeminal nerve may be affected. Neuralgia of the first branch leads to pain around the eyes and over the forehead; the second branch causes pain in the upper lip, nose and cheek; the third branch causes pain on the side of the tongue and lower lip.

The first episodes are usually fairly mild and brief, and it may be minutes, hours, or weeks before the next attack. However, attacks tend to occur in clumps that may last for weeks at a time. As the sufferer ages, the episodes become more frequent and painful, until the person begins to live in constant fear of the next one.



Trigeminal neuralgia is a disorder of the trigeminal nerve (which is divided into three branches, as illustrated above) that causes episodes of sharp, stabbing pain in the cheek, lips, gums, or chin on one side of the face. The origin of this disorder is not certain, but scientists believe it may be caused by degeneration, pressure, or irritation of the trigeminal nerve. *(Illustration by Electronic Illustrators Group. Reproduced by permission of Gale, a part of Cengage Learning.)*

KEY TERMS

Multiple sclerosis—A progressive disease of the central nervous system in which the coverings of nerves in the brain and spinal cord are destroyed.

The momentary bursts of pain usually begin from the same spot on the face each time. The pain can be triggered by touching the area, washing, shaving, eating, drinking, or even talking. Even a cool breeze across the face can set off an attack. Pain is more severe at the ends of the affected nerve, especially over the lip, chin, nostrils, or teeth.

Diagnosis

Diagnosis is usually made by eliminating other problems that could cause similar pain in teeth, jaw, head, or sinuses. Because patients with the condition tend to avoid trigger points, avoiding chewing, shaving, touching or washing their faces can be a clue to diagnosis of trigeminal neuralgia.

Treatment

It is not easy to treat trigeminal neuralgia. Pain can be suppressed by a range of medicines, including the anti-epilepsy medicines carbamazepine (Tegretol) or phenytoin (Dilantin). These drugs slow down the nerve signals at certain nerve terminals, which eases the pain. However, these drugs cause a wide range of side effects, including **nausea**, **dizziness**, drowsiness, liver problems, and skin **allergies**. Some people develop resistance to the drugs or they can't tolerate the high dosage needed to control the discomfort. If the medicines are stopped, the pain usually returns.

If drug treatment fails, surgical treatment to block pain signals from the nerve may be effective. Radiofrequency waves, gamma rays, or glycerol injections can deaden the nerve (and hence the pain). An operation that frees the nerve from whatever is compressing it (blood vessel or tumor) can permanently relieve pain, but this major neurosurgical procedure carries its own risks and complications. Alternatively, a new procedure seeks to place a cushioning sponge between the nerve and a pulsating artery wrapping around it to soothe the irritated nerve.

Prognosis

Although the pain is momentarily incapacitating, it's not life-threatening. As the person ages, the attacks can be expected to occur more and more frequently.

Prevention

While the condition itself can't be prevented, there are a number of things patients can do to avoid triggering attacks:

- wash with cotton pads and warm water over the face
- rinse the mouth with water after eating, if toothbrushing triggers pain
- eat and drink food and beverages at room temperature
- chew on the unaffected side
- eat soft foods, if eating is becoming a problem

Carol A. Turkington

Trigger finger

Definition

Trigger finger is the popular name of stenosing tenosynovitis, a painful condition in which a finger or thumb locks when it is bent (flexed) or straightened (extended).

Description

Tendons are tough, fibrous cords that connect muscles to bones. Tendons must slide easily through their protective coverings (tendon sheaths). The finger and thumb bones have tendons that are responsible for bending and straightening the fingers. Problems start when a tendon sheath narrows (stenosis) and the outer covering of the tendon becomes inflamed (tenosynovitis). The tendon swells because of the constriction, sometimes forming a nodule, and is no longer able to move smoothly through its sheath. As a result, a finger may lock in an upward position as the person tries to straighten it. The condition usually happens in the ring and middle fingers and is more common in

KEY TERMS

Microcirculation—The passage of blood in the smallest blood vessels of the body, such as the capillaries in the hand and fingers.

Myofascial—The fibrous tissue that encloses and separates layers of muscles.

Nodule—A swelling or knob that may form on a tendon and make it difficult to slide smoothly through its sheath.

Stenosis—Narrowing of a passageway or opening in the body. In trigger finger it is the tendon sheath that narrows.

Synovial tendon sheath—Where the tendons cross joints, they are sheathed in thin membranes known as synovium, which provide lubrication to decrease friction.

Tendon sheath—A membrane covering a tendon.

Tenosynovitis—Inflammation of a tendon and its enveloping sheath, usually resulting from overuse injury.

women, typically over age 30. In infants and small children, the condition generally occurs in the thumb.

Causes and symptoms

Trigger finger is often an overuse injury because of repetitive or frequent movement of the fingers. Trigger finger may happen because a person performs the same manipulation over and over on a job, from squeezing and gripping during a weekend of heavy pruning and gardening, or from such hobbies as playing a musical instrument or crocheting. Trigger finger may also result from trauma or accident. The symptoms of trigger finger are **pain** in the fingers and "popping" sensations. Sometimes the finger may lock down into the palm or lock out straight. Symptoms are usually worse in the morning and improve during the day.

Diagnosis

The diagnosis of trigger finger and thumb is obvious on **physical examination**. Often there is a click that can be felt as the nodule passes through the sheath. Most cases are uncomplicated although x rays are often taken to rule out other injuries or disease such as arthritis.

Treatment

Initial treatment for mild or infrequent symptoms of trigger finger include rest, avoiding or modifying those activities that caused the inflammation, and the use of a nonsteroidal anti-inflammatory drug (NSAID) such as ibuprofen. This may relieve the swelling and inflammation that resulted in the constriction of the sheath and the restriction of the tendon. Injection of a steroid medication (cortisone) into the tendon sheath is the next option to treat trigger finger. Depending on the severity, there may be one more injection a week later. Two-thirds of patients improve after one injection. Some physicians will splint the finger in extension after the injection.

In severe cases that do not respond to injections and the finger or thumb remains in a locked position, surgery may be required to relieve the symptoms. A local anesthetic is used for the surgical procedure performed on an outpatient basis. An incision is made by a surgeon in the palm of the hand at the base of the affected finger or thumb to relieve the constriction of the tendon. Recovery may take up to four weeks. Sometimes **physical therapy** of the hand is required after surgery to regain good use.

Alternative treatment

Treatment should begin when a person starts having difficulty moving the fingers. If started early, noninvasive measures have a good chance for success. Alternative treatments include **acupuncture** to facilitate healing and microcirculation, pulsed ultrasound, and myofascial release work for the affected area.

Prognosis

At least half of cases can be cured non-surgically. The key to successful treatment is early intervention. A mistake people make is trying to work through the pain. Diabetics have a higher incidence of the condition and are sometimes left with a disability.

Prevention

Taking frequent breaks from a repetitive activity will do much to prevent the condition. Depending on the intensity, that may mean a 10-minute break every hour from the repetitive activity. The break should be spent stretching the hands and arms and generally moving around.

Ruthan Brodsky

Triglycerides

Definition

Triglycerides are a form of fat, consisting of three molecules ("tri") of a fatty acid combined with one molecule of the alcohol glycerol. Triglycerides serve as the backbone of many types of lipids (fats). Triglycerides are produced by the liver as well as are ingested as part of the diet. Fats in foods are digested and changed to triglycerides.

Purpose

Triglycerides have several purposes in physiology. Triglycerides travel through the circulatory system and are either utilized immediately or are stored in adipose tissue, thereby serving as the most abundant form of stored energy in the body. Triglycerides can serve as this important storage medium because of their hydrophobicity, which allows them to be stored as droplets, without contact with water molecules. Often a typical human body may contain several months of fuel stored in the form of triglycerides. When physiological conditions dictate the need to use the triglycerides, hormones or a neurotransmitter signal their release. This release may be in response to **exercise**, **stress**, or **fasting**. An enzyme called lipase breaks down the triglyceride molecule into a glycerol molecule and three fatty acids before release from the adipose tissue. These breakdown products are transported within the circulatory system to the tissues that need them for energy.

In addition to serving as a source of energy, triglycerides carry the fat-soluble **vitamins** (including vitamin K, an important nutrient in normal blood coagulation). Triglycerides also provide thermal insulation and contribute to the structure of membranes by the formation of a lipid bilayer.

Triglyceride levels

Normal	Less than 150 mg/dL
Borderline-high	150–199 mg/dL
High	200–499 mg/dL
Very high	500 mg/dL or above

SOURCE: National Heart, Lung and Blood Institute, National Institutes of Health, U.S. Department of Health and Human Services

Healthy (normal) and unhealthy triglyceride levels. *(Table by PreMediaGlobal. Reproduced by permission of Gale, a part of Cengage Learning.)*

Triglycerides combine with a blood protein to form chemicals referred to as high-density and low-density lipoproteins. These lipoproteins contain cholesterol, another substance related to fats.

Description

It is not yet clear whether high triglyceride levels act as a predictor of the risk for heart disease and heart attacks, especially in persons with normal levels of cholesterol. Some health care professionals feel that elevated triglycerides are a marker for other risk factors that do impact the risk of heart disease, that is, high levels of triglycerides are usually associated with low levels of high density lipoproteins, usually referred to as the "good" cholesterol.

However, there are some indications that high triglycerides may serve as a predictor for heart disease, especially in women. In a study involving postmenopausal women (aged 48 to 76 years old) conducted by a research group from the Center for Clinical and Basic Research in Ballerup, Denmark, it was found that women who had an enlarged waist and elevated levels of triglycerides had almost a five-fold increased risk of fatal cardiovascular events compared to women without those traits. The women at risk deposited fat centrally in their intra-abdominal compartment, rather than in their hips, thighs, and buttocks.

The mechanism of how triglycerides might affect heart health is not fully known, but it appears that elevated levels of triglycerides may allow increased blood clot formation and may slow the natural breakdown of clots after they have formed. However, high levels of triglycerides may mean an increased risk of diabetes, and very high levels of triglycerides may increase the risk of inflammation of the pancreas, resulting in **pancreatitis**.

Triglyceride levels are evaluated through blood testing.A fatty meal that is high in triglycerides will cause a short term increase in blood triglyceride levels. Therefore, before testing, a person should refrain from eating food for eight to ten hours before the test and not drink alcohol for 24 hours before the test. Some medications may interfere with test results, and the health care provider may request that the person cease taking the medications before testing. For example, **oral contraceptives**, estrogen, and cholestyramine (a drug used to treat high cholesterol levels) may increase blood triglyceride levels, while vitamin C (ascorbic acid), asparaginase (an enzyme used in the treatment of **cancer**), and various drugs to treat high levels of blood lipids may decrease blood triglyceride levels. Triglyceride levels can also be affected by the

menstrual cycle, time of day, and recent exercise. A person should have two or three tests, one week apart, for the most accurate results.

The normal range of blood triglyceride levels depends on age and gender, with women naturally having higher levels, especially when pregnant. As people age and gain weight, triglyceride levels usually increase. According to the guidelines promulgated by the National Cholesterol Education Program, a division of the National Heart, Lung, and Blood Institute, a normal fasting level for adults is less than 150 milligrams per deciliter (mg/dL), with levels below 101 considered desirable. Levels of 150–199 mg/dL are considered borderline high, levels of 200–499 mg/dL are considered high, with levels greater than 500 mg/dL considered very high. Such high levels may indicate **liver disease** (**cirrhosis**), underactive thyroid activity, uncontrolled diabetes, pancreatitis, **kidney disease**, or a diet too low in protein and too high in carbohydrates.

Extremely low levels of triglycerides (less than 10 mg/dL) may indicate **malnutrition**, malabsorption, a diet too low in fat, or an overactive thyroid.

High triglyceride levels may be due to several causes, including:

- Lifestyle factors
- Weight gain
- Lack of exercise
- Smoking
- Skipping meals
- Eating large portions of food at one time
- Dietary factors
- Excessive intake of alcohol, saturated and trans fats, sugar, starch, and calories
- Medical conditions
- Medicines, including birth control pills, steroids, and diuretics
- Illnesses, including poorly controlled diabetes, insulin resistance (a precursor to diabetes), polycystic ovary syndrome (PCOS), hypothyroidism, kidney disease, and liver disease
- Age

Hereditary may also play a role in elevated levels of triglycerides. Familial hypertriglyceridemia is a common inherited disorder in which the level of triglycerides in a person's blood is higher than normal. This disorder is an autosomal dominant disorder, that is, if one parent has an abnormal gene and the other parent a normal gene, there is a 50% chance each child will inherit the abnormal gene and therefore the dominant trait. Some people with this condition also have high levels of very low density lipoprotein (VLDL), the "bad" cholesterol. **Obesity**, hyperglycemia (high blood glucose levels), and high levels of insulin are often associated with this condition and may result in even higher triglyceride levels.

Familial hypertriglyceridemia is not usually detected until **puberty** or early adulthood. Symptoms include a mild-to-moderate increase in blood triglyceride levels and premature **coronary artery disease**. Persons with this condition are also at increased risk for pancreatitis.

Familial hypertriglyceridemia occurs in about 1 in 500 individuals in the United States. Risk factors are a family history of hypertriglyceridemia or a family history of heart disease before the age of 50. If triglyceride levels cannot be not controlled by dietary and lifestyle changes, medication may be needed. Nicotinic acid and gemfibrozil have been shown to effectively reduce triglycerides in persons with familial hypertriglyceridemia. Screening family members for elevated levels of triglycerides may help to detect the disease early.

A nutritionist or dietitian may be consulted to help develop a dietary plan to help control triglyceride levels. In general, to lower or prevent high levels of triglycerides, a person should:

- Lose weight
- Get regular exercise
- Eat less sugar and sugar-containing foods
- Eat smaller meals and snacks throughout the day, rather than consuming two or three large meals
- Drink less alcohol (even small amounts of alcohol has been shown to elevate triglycerides)
- Limit fat in the diet to less than 35% of daily calories
- Avoid deep-fried foods
- Substitute monounsaturated and polyunsaturated fats, such as those found in canola or olive oils, for saturated fats
- Use a prescription medicine, as directed by the health care provider, to decrease the production of triglycerides by the liver
- Instead of eating meats high in saturated fats, consume fish high in omega-3 fatty acids, such as salmon, lake trout, herring, sardines, albacore tuna, or mackerel (about 10 to 15 grams of fish oil a day is recommended; 15 grams of fish oil can be obtained from an 8-ounce serving of fish)

Other good food choices include fruits (but not fruit juices, which are high in sugar), vegetables, whole grain breads and cereals, lean protein sources, such as lean meats, poultry without skin, eggs, egg substitute or egg white, cooked dried beans, lentils, peas, nuts, and low-fat soy products, fat-free or 1% milk products, nuts such as almonds, walnuts, and peanuts, avocados, and sugar-free products.

One approach to successfully changing the diet to reduce blood triglyceride levels is to make changes in stages. For example, individuals could cut fat intake to 30% for one month (current American levels are approximately 40%) and then return to their health care provider to see if there has been an improvement in their triglyceride levels. If the level of decreases was not satisfactory, the individuals could further restrict their fat intake to 25% and again be evaluated after one month. If no improvement is noted, the fat intake should be lowered to 20% for two months. At this level of fat intake, it is likely that most calories are being obtained from complex carbohydrates, and a reduction in triglyceride levels should be seen.

Complications

Other risk factors for coronary heart disease can increase the hazards from high levels of triglycerides. Therefore a person with high levels should in addition to making dietary changes should also control high blood pressure and avoid cigarette **smoking**. Dietary management is important even when drugs are used to control triglyceride levels.

Parental concerns

If a child is suspected to have familial hypertriglyceridemia, the child should be tested for elevated levels of triglycerides. If the disorder is present, appropriate steps should be taken to help the child lower his or her triglyceride levels.

Triglycerides test

Definition

Triglycerides test is a blood test to determine the amount of triglycerides, a form of fat, in the blood.

Purpose

The triglycerides test is one of the screening tests for excess lipids (fats) in the blood. It is usually part of an evaluation of risk factors for heart disease.

Description

Triglycerides are a form of fat that comes from foods. They can also be made and stored in the body and are used as an energy source. High levels of triglycerides in the blood can mean that there is too much fat in the diet. Hypertriglyceridemia (high levels of triglycerides) is associated with coronary heart disease, especially since elevated triglycerides levels are often associated with unhealthy low levels of hyper-density lipoproteins (the "good" cholesterol), which are necessary for good health.

Preparation

For triglycerides testing, blood is drawn from a vein in the arm. A vein at the inside of the elbow or on the back of the hand is usually selected. The area where the needle will be inserted is cleaned with antiseptic. A small needle is inserted through the skin and into the vein, allowing a small amount of blood to flow into a collection tube or syringe. Once the blood is collected, the needle is removed from the puncture site.

Before the blood test, the patient may be required to refrain from eating food from eight to 12 hours. Patients should not drink alcohol for 24 hours before the test. Some drugs may affect the test and the patient may be asked to cease taking certain medications before the test. **Oral contraceptives**, estrogen, and cholestyramine (a drug used to treat high cholesterol) can increase triglyceride levels. Ascorbic acid (vitamin C), asparaginase (an enzyme), and various drugs used to treat high blood lipids, can decrease blood triglyceride levels. These substances should not be taken prior to this test.

Aftercare

After the blood sample has been taken and the needle withdrawn from the puncture site, a cotton ball or gauze pad may be placed over the site and direct pressure applied to reduce bleeding. A piece of surgical tape or gauze adhesive bandage strip may be secured over the site to prevent further bleeding.

Risks

There is a very small risk that the puncture site may bleed excessively, a bruise or infection may develop at the site, or it may take several punctures to locate a vein. Some patients may feel faint or lightheaded when blood is drawn.

Normal results

The normal range of triglycerides in the blood depends on the age and gender of the patient. Women naturally have higher levels of triglycerides than men. **Pregnancy** can also increase triglyceride levels. As people age and gain weight, triglyceride levels generally increase. For adults, a normal level is considered to be less than 200 mg/dL (milligrams per deciliter). Levels from 200–400 mg/dL are considered borderline high.

Abnormal results

Triglyceride levels ranging from 400-1000 mg/dL are considered high and levels greater than 1000 mg/dL are considered very high. High levels of triglycerides may indicate **liver disease** (**cirrhosis**), an underactive thyroid problem, uncontrolled diabetes, an infection of the pancreas (**pancreatitis**), **kidney disease**, or a diet too low in protein and too high in carbohydrates.

Extremely low triglycerides levels (less than 10 mg/dL) can also indicate a problem. Low levels may indicate **malnutrition** (not enough nutrients in the diet), malabsorption (inadequate absorption of nutrients in the intestinal tract), a diet too low in fat, or an overactive thyroid problem.

Triple screen

Definition

Triple screen is a blood test offered to pregnant women during the 16th-18th week of **pregnancy** to help identify if the unborn baby is at risk for **birth defects**.

Purpose

Researchers have found that women carrying a fetus with **Down syndrome** tend to have three substances in their blood in a distinctive abnormal pattern. Both alpha-fetoprotein (AFP), a protein produced by the fetus, and unconjugated estriol (uE3), a hormone manufactured by both the fetus and the placenta, are lower than normal, while human chorionic gonadotropin (hCG), a hormone produced in the placenta, is higher. The level of each substance is then divided by the median concentration of that substance for the given week of pregnancy to generate a multiple of the median value (MOM). These values, along with other characteristics of the mother, such as her age, are analyzed by a computer program to indicate the probability that the fetus has Down syndrome. Down syndrome is a condition that includes **mental retardation**, skeletal abnormalities such as upslanted eyes and **cleft palate**, and organ abnormalities such as heart disease and intestinal obstruction.

Guidelines developed from this research help healthcare workers to determine whether the risk for any one pregnancy is clearly different from that for the general population of the same age. For example, the average 25-year-old woman has one chance in a 1,000 of bearing a Down syndrome baby. After her blood is analyzed for the three hormones, her risk can be refigured. It might be considerably lower—or higher—than average.

The triple screen was first aimed toward detecting fetuses at high risk for Down syndrome, an abnormality that comes about when, at fertilization, the embryo receives three copies of chromosome 21 instead of the usual two. For unknown reasons, extra amounts of genetic material are usually associated with severe developmental defects. Although Down syndrome is the most common such disorder, it is by no means the only one. Chromosomes 13 or 18 can also turn up as a triple set (or trisomy). An abnormal pattern of the three hormones sometimes signals one of these trisomies or another, more rare chromosomal disorder.

Precautions

It is important that the correct age of the unborn baby be determined by last menstrual period dating and recorded for the risk calculation. Errors in determining the age of the fetus lead to errors when interpreting the test results. Since an AFP test is only a screening tool, an abnormal test result is not necessarily indicative of a birth defect. Accurate dating of the fetus lowers the false-positive and false-negative rates associated with this screening test.

Description

Prior to 1964, when the association between low levels of AFP and an increased risk for Down syndrome was reported, risk assessment for chromosomal diseases was based upon maternal age. At age 35, the risk of carrying a Down syndrome pregnancy is approximately one in 270, and this was deemed sufficient to warrant **amniocentesis**, a more accurate but invasive test that

KEY TERMS

Amniocentesis—A test performed to determine the health, sex, or genetic constitution of a fetus by taking a sample of amniotic fluid through a needle inserted into the womb of the mother.

Amniotic fluid—The fluid that surrounds a fetus while it is developing. It is the fluid that flows out in the "breaking of the water" before a baby is born.

Down syndrome—A genetic disorder characterized by a broad skull, blunt facial features, short stature, and learning difficulties. It is caused by the presence of an extra copy of chromosome 21.

Placenta—An organ that develops inside the uterus of pregnant women to supply food and oxygen to the fetus through the umbilical cord.

involves using a needle to draw out a sample of the embryonic fluid that surrounds the fetus. However, three of four Down syndrome pregnancies occur in women under 35 years old. When AFP testing was used along with maternal age, the rate of detection of Down syndrome increased to about 45%, but this level of sensitivity did not justify the screening of younger women because of the risk of **miscarriage**. The inclusion of uE3 and hCG testing has improved the detection rate to approximately 65-80% of cases for all age groups. The triple screen test costs $90-250 and is covered by most insurance plans.

Preparation

There is no specific physical preparation for this test. **Fasting** is not required.

Aftercare

After the blood sample is drawn, pressure should be applied to the puncture site until the bleeding stops to reduce bruising. A bandage or taped ball of cotton may be applied to the site. A warm pack may be applied to the site to relieve discomfort.

Risks

The complications associated with drawing blood are minimal, but may include bleeding from the puncture site, feeling faint or lightheaded after the blood is drawn, or blood accumulating under the puncture site (hematoma).

Normal results

Results are expressed as multiples of the median value used by the laboratory. Normal ranges expressed in concentration (for example, ng/mL) are dependent upon the age of the fetus, but MOMs are age-adjusted and do not change. These values are used to calculate risk. If the multiple of the median value is below 2.0 MOM or 2.5 MOM (depending on the laboratory), the fetus is considered to be at a lower risk for a genetic defect.

Abnormal results

If the multiple of the median value is above 2.0 MOM or 2.5 MOM (depending on the laboratory), the fetus is considered to be at a higher risk for a genetic defect. The MOM value for amniotic fluid is then used to calculate the exact probability the fetus is affected (1:100, for example). With respect to Down syndrome and trisomy 18, the MOM values are also used in the calculation of probability. The woman is considered to be "high risk" or "screen positive" for Down syndrome if the risk is greater than the standard risk for women who are 35 years old or older (one in 270). For trisomy 18, the cut-off is one in 150. In one study the triple marker screen test had a detection rate for Down syndrome of 67% and a false positive rate of 5%.

Tropical spastic paraparesis

Definition

Tropical spastic paraparesis (TSP) is an incurable viral infection of the spinal cord that causes weakness in the legs. It is caused by the human T-cell lymphotropic virus-1 (HTLV-1) retrovirus.

Description

As the name implies, tropical spastic paraparesis usually occurs in tropical locales. Although isolated cases have been diagnosed in the southeastern United States and other places in the United States, TSP is most frequently found in:

- the Caribbean
- Japan
- the Seychelles Islands
- regions of South America
- western Africa

TSP usually affects adults between the ages of 30 and 40, and is far more common in women than in men.

The disease may remain undetected for years after infection is contracted. When the immune system's response to the virus causes nerve damage, the legs gradually lose strength and flexibility.

Causes and symptoms

TSP is caused by the HTLV-1 virus, which also causes leukemia. The virus can be spread through the placenta, and also through blood transfusions, **breast-feeding**, contaminated needles, and sexual contact.

Symptoms may begin years after infection. In response to the infection, the body's immune response may injure nerve tissue, causing symptoms that include bladder abnormalities, leg **pain**, loss of feeling in the feet, **tingling** sensations, and unpleasant sensations when the skin is touched.

As many as 20% of patients with TSP may also experience:

- deafness
- double vision
- the tendency to incorrectly estimate the amount of motion necessary to accomplish a specific task (dysmetria)
- exaggerated reflexes
- facial paralysis
- tremor.

KEY TERMS

Retrovirus—A family of RNA viruses containing a reverse transcriptase enzyme which allows the viruses' genetic information to become part of the genetic information of the host cell upon replication.

Virus—A microorganism, smaller than bacteria, which can replicate only within the a cell of a living plant or animal. The virus provides the genetic code and the host cell provides the energy and raw materials for replication.

Diagnosis

Infectious disease specialists use blood tests and **magnetic resonance imaging** (MRI) of the spinal cord to diagnose this condition.

Treatment

While the disease is incurable, significant improvement has been reported in the condition of TSP patients treated with **corticosteroids**. These drugs are believed to alleviate symptoms by suppressing the immune system's response to the virus that causes them.

Plasmapheresis, a dialysis-like procedure in which symptom-producing antibodies are removed from the blood, also provides temporary relief.

Prognosis

As noted, TSP cannot be cured.

Prevention

The United States Food and Drug Administration (FDA) has approved screening procedures developed to detect HTLV-1 in donated blood and blood products designated for **transfusion**. These procedures, which can also be used to diagnose patients with TSP, are designed to prevent the spread of the disease.

Troponins test

Definition

Troponins are specific proteins found in heart muscle. Troponin testing is done to diagnose heart attacks (myocardial infarctions).

Purpose

When heart muscle is damaged, as in a myocardial infarction (MI), troponins leak out of cells and into the bloodstream. Increased troponin levels indicate myocardial infarction or injury in a person with chest **pain** or pressure. Some MIs are silent, manifesting few if any symptoms.

If infarction is ruled out in a person with continuing or recurring chest pain (unstable **angina**), an increased troponin level indicates the person has heart muscle **ischemia** (a decreased supply of oxygenated blood to the body), and is at an increased risk for a future serious heart event.

Description

Although troponins also exist in other muscles, those in the heart are unique, and are measured separately in laboratory tests. Troponins in the heart are called cardiac troponins. There are two main types of cardiac troponins; T and I. T is also referred to as cTnT, while I is also referred to as cTnI.

Both troponin T and I are cardiac markers used to diagnose myocardial infarctions. Cardiac markers are substances whose blood levels increase after a myocardial infarction. Others include CK (creatine kinase), myoglobin, and CK-MB (one of three CK isoenzymes).

Like all cardiac markers, troponins have a unique diagnostic window (the timeline during which the marker rises, peaks, and returns to normal). Troponin levels rise within four to six hours after the beginning of chest pain or heart damage, and stay elevated for at least one week. This long elevation allows detection of a myocardial infarction that occurred days earlier, but prevents detection of a second infarction if it occurred only days after the first.

Troponins I and T are considered superior cardiac markers for several reasons. The most significant is that cardiac troponins are the only markers specific for heart muscle. Other markers also increase following damage to other muscles. Troponin levels help predict the extent of heart muscle damage; higher levels are associated with increased damage, lower levels with less damage. Levels in a healthy person are negligible, so an increase is easily detected.

KEY TERMS

Angina—A temporary chest pain caused by the heart not receiving enough oxygen.

Cardiac marker—A substance in the blood whose level rises following a myocardial infarction.

Myocardial infarction—Commonly known as a heart attack, a myocardial infarction is an episode in which some of the heart's blood supply is severely cut off or restricted, causing the heart muscle to suffer and die from lack of oxygen.

The main difference between troponins I and T is that cardiac troponin I tests measure only cardiac troponin; tests for cardiac troponin T may cross-react with troponin found in other muscles and give positive or increased results in the absence of heart damage.

Two types of tests for troponins T and I are available: a traditional quantitative test that provides an actual measurement of troponin, and a newer qualitative test that simply reports the result as positive or negative. The quantitative test takes 45–90 minutes, and helps distinguish between myocardial infarction and unstable angina. The qualitative test takes 15 minutes and is used in emergency rooms in which rapid patient care decisions can be made based on the presence or absence of troponins.

Preparation

Troponins tests require 5 mL of blood. Collection of the sample takes only a few minutes.

Aftercare

Discomfort or bruising may occur at the puncture site or the person may feel dizzy or faint. Pressure to the puncture site until the bleeding stops reduces bruising. Warm packs to the puncture site relieve discomfort.

Normal results

People without heart damage have troponin levels less than 0.5 ng/mL.

Abnormal results

Levels greater than 2.0 ng/mL indicate a person has had a significant myocardial injury, such as an infarction, and is at an increased risk for future serious heart events. Levels between 0.5 and 2.0 ng/mL indicate a diagnosis of unstable angina, other heart disorders, or **chronic kidney failure**.

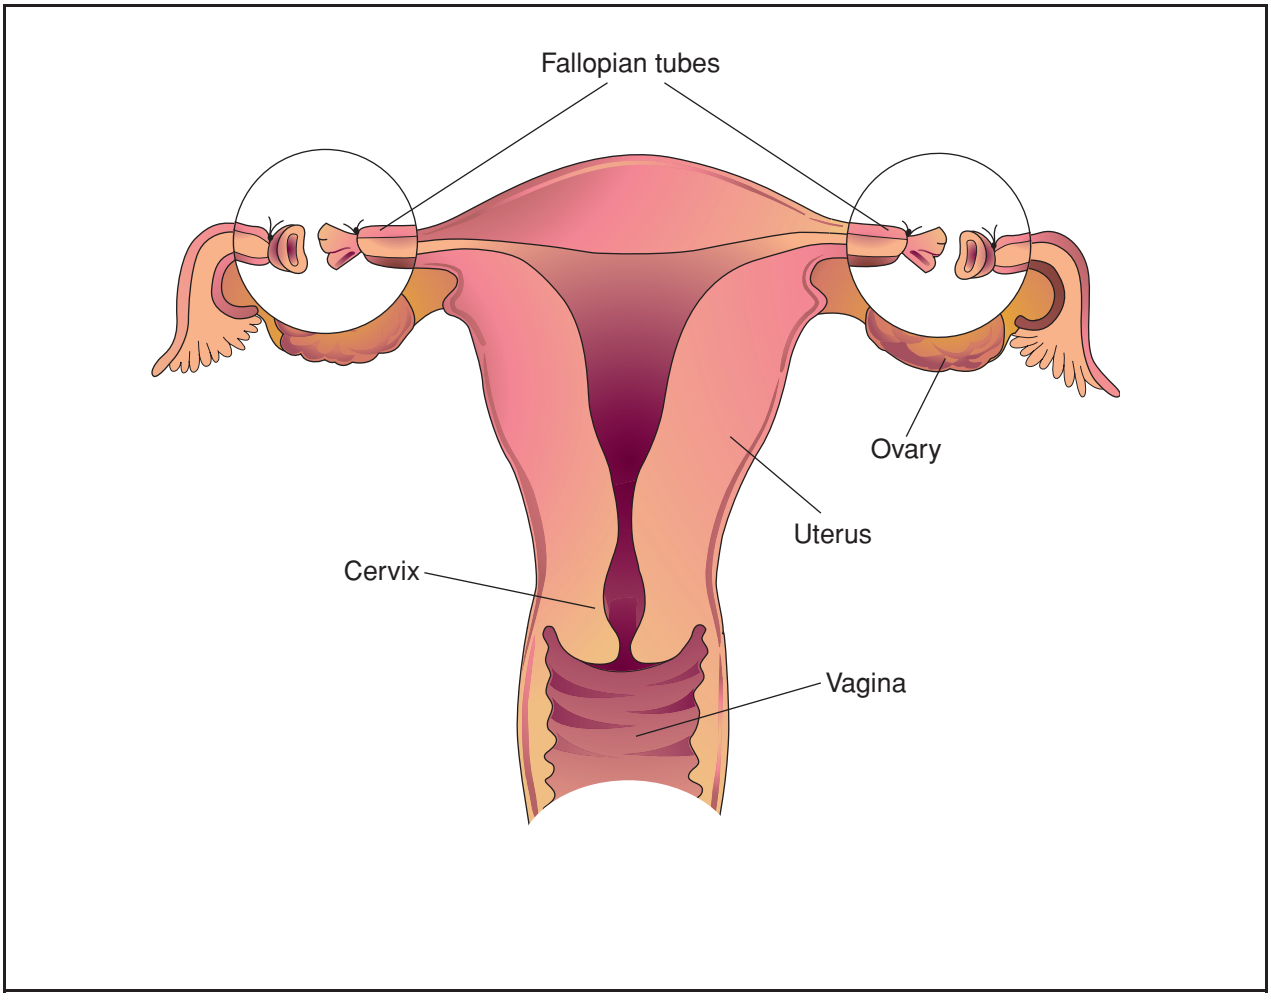
Tubal ligation

Definition

Tubal ligation is a permanent voluntary form of birth control (**contraception**) in which a woman's fallopian tubes are surgically cut, tied, or blocked off to prevent **pregnancy**.

Purpose

Tubal ligation is performed in women who want to prevent future pregnancies. It is frequently chosen



Tubal ligation is a permanent form of contraception in which a woman's Fallopian tubes are surgically cut, cauterized, tied, or blocked to prevent pregnancy. This procedure blocks the pathway sperm takes to fertilize an egg. *(Illustration by Electronic Illustrators Group. Reproduced by permission of Gale, a part of Cengage Learning.)*

by women who do not want more children, but who are still sexually active and potentially fertile, and want to be free of the limitations of other types of birth control. Women who should not become pregnant for health concerns or other reasons may also choose this birth control method.

Demographics

Tubal ligation is one of the leading methods of contraception. This form of contraception is chosen by about 650,000–700,000 annually in the United States. The typical tubal ligation patient is over age 30, is married, and has had two or three children.

Description

Tubal ligation, or getting one's "tubes tied," refers to female sterilization, the surgery that ends a woman's ability to conceive. The operation is performed on the patient's fallopian tubes. These tubes, which are about 4 in (10 cm) long and 0.2 in (0.5 cm) in diameter, are found on the upper outer sides of the uterus. They open into the uterus through small channels. It is within the fallopian tube that fertilization, the joining of the egg and the sperm, takes place. During tubal ligation, the tubes are cut or blocked in order to close off the sperm's access to the egg.

Normally, tubal ligation takes about 20–30 minutes, and is performed under **general anesthesia**, spinal anesthesia, or **local anesthesia** with **sedation**. The surgery can be performed on either hospitalized patients within 24 hours after **childbirth** or on outpatients. The woman can usually leave the hospital the same day.

Tubal ligation should be postponed if the woman is unsure about her decision. While the procedure is sometimes reversible, it should be considered permanent and irreversible. As many as 10% of sterilized women regret having had the surgery, and about 1% seek treatment to restore their fertility.

The most common surgical approaches to tubal ligation include **laparoscopy** and mini-laparotomy. In a laparoscopic tubal ligation, a long, thin telescope-like surgical instrument called a laparoscope is inserted into the pelvis through a small cut about 0.5 in (1 cm) long near the navel. Carbon dioxide gas is pumped in to help move the abdominal wall to give the surgeon easier access to the tubes. Often, the surgical instruments are inserted through a second incision near the pubic hair line. An instrument may be placed through the vagina to hold the uterus in place.

In a mini-laparotomy, a 1–2 in (3–4 cm) incision is made just above the pubic bone or under the navel. A larger incision, or laparotomy, is rarely used today. Tubal ligation can also be performed at the time of a **cesarean section**.

KEY TERMS

Contraception—The prevention of the union of the male's sperm with the female's egg.

Ectopic pregnancy—The implantation of a fertilized egg in a fallopian tube instead of the uterus.

Electrocoagulation—The coagulation or destruction of tissue through the application of a high-frequency electrical current.

Female sterilization—The process of permanently ending a woman's ability to conceive by tying off or cutting apart the fallopian tubes.

Laparoscopy—Abdominal surgery performed through a laparoscope, which is a thin telescopic instrument inserted through an incision near the navel.

Laparotomy—A procedure in which the surgeon opens the abdominal cavity to inspect the patient's internal organs.

Vasectomy—Surgical sterilization of the male, done by removing a portion of the tube that carries sperm to the urethra.

The tubal ligation itself is performed in several ways, including:

- Electrocoagulation. A heated needle connected to an electrical device is used to cauterize or burn the tubes. Electrocoagulation is the most common method of tubal ligation.
- Falope ring. In this technique, an applicator is inserted through an incision above the bladder and a plastic ring is placed around a loop of the tube.
- Hulka clip. The surgeon places a plastic clip across a tube held in place by a steel spring.
- Silicone rubber bands. A band placed over a tube forms a mechanical block to sperm.

Tubal ligation costs between $2,000 and $2,500 when performed by a private physician, but is less expensive when performed at a family planning clinic. Most insurance plans cover treatment costs.

Diagnosis/Preparation

Preparation for tubal ligation includes patient education and counseling. Before surgery, it is important that the woman understand the permanent nature of

tubal ligation as well as the risks of anesthesia and surgery. Her medical history is reviewed, and a **physical examination** and laboratory testing are performed. The patient is not allowed to eat or drink for several hours before surgery.

Aftercare

After surgery, the patient is monitored for several hours before she is allowed to go home. She is instructed on care of the surgical wound, and what signs to watch for, such as **fever**, **nausea**, **vomiting**, faintness, or **pain**. These signs could indicate that complications have occurred.

Risks

While major complications are uncommon after tubal ligation, there are risks with any surgical procedure. Possible side effects include infection and bleeding. After laparoscopy, the patient may experience pain in the shoulder area from the carbon dioxide used during surgery, but the technique is associated with less pain than mini-laparotomy, as well as a faster recovery period. Mini-laparotomy results in a higher incidence of pain, bleeding, bladder injury, and infection compared with laparoscopy. Patients normally feel better after three to four days of rest, and are able to resume sexual activity at that time.

The possibility for treatment failure is very low—about five women per 1,000 will become pregnant during the first year after sterilization. The failure rate increases over time, so that 10 years after the procedure, the failure rate is 18 women per 1,000. Failure can happen if the cut ends of the tubes grow back together; if the tube was not completely cut or blocked off; if a plastic clip or rubber band has loosened or come off; or if the woman was already pregnant at the time of surgery.

Normal results

After having her tubes tied, a woman does not need to use any form of birth control to avoid pregnancy. Tubal ligation is almost 100% effective for the prevention of conception.

Morbidity and mortality rates

About 1–4% of patients experience complications following tubal ligation. There is a low risk (less than 1%, or seven per 1,000 procedures) of a later **ectopic pregnancy**. Ectopic pregnancy is a condition in which the fertilized egg implants in a place other than the uterus, usually in one of the fallopian tubes. Ectopic pregnancies are more likely to happen in younger women, and in women whose tubes were closed off by electrocoagulation.

Rarely, **death** may occur as a complication of general anesthesia if a major blood vessel is cut. The mortality rate of tubal ligation is about 4-in-100,000 sterilizations.

Alternatives

There are numerous options available to women who wish to prevent pregnancy. **Oral contraceptives** are the second most common form of contraception—the first being female sterilization—and have a success rate of 95–99.5%. Other methods of preventing pregnancy include **vasectomy** (99.9% effective) for the male partner; the male condom (86–97% effective); the diaphragm or cervical cap (80–94% effective); the female condom (80–95% effective); and abstinence.

Tube compression of the esophagus and stomach

Definition

Tube compression of the esophagus and stomach is an emergency procedure used to stop bleeding from the upper digestive tract.

Purpose

Vomiting blood is both frightening and life-threatening. Among its causes are:

- bleeding from the nose and throat
- peptic ulcers
- stomach cancer
- esophageal cancer
- a tear in the esophagus caused by violent vomiting (Mallory-Weiss syndrome)
- breaking of blood vessels in the esophagus.

The most profuse bleeding comes from veins in the lower esophagus, just above the stomach, that have dilated to enormous dimensions as the result of **liver disease**. When the liver shrinks due to **cirrhosis** (scarring from chronic disease), its blood vessels shrink, forcing blood from the intestines to find alternate routes back to the heart. The blood usually flows through tiny veins in the esophagus located just beneath the passageway where food passes downward and vomitus passes upward. Major causes for this rearrangement are alcoholic liver disease, chronic hepatitis, and **cholangitis**. Called esophageal varices, the affected veins can be easily damaged and bleed voraciously.

Description

One emergency method of stopping bleeding from esophageal varices is to tamponade it with a balloon. The Sengstaken-Blakemore tube is a complex rubber device with two balloons and three channels—one channel for each balloon and one that goes all the way through. The Minnesota tube has four channels, an extra one that opens above the first balloon. The bottom balloon is round; the upper balloon is long and narrow. The tube is passed through the nose or mouth into the stomach, where the bottom balloon is inflated. Then the tube is pulled back until the bottom balloon comes up against the narrow valve at the top of the stomach, when it can go no further. At this point, the upper balloon is inflated, putting pressure on a length of esophagus where the bleeding veins are located. The tube is then fixed so it cannot be dislodged. The third channel in the tube is used to aspirate (suck out) stomach contents to see if the bleeding has stopped. The fourth channel aspirates from the esophagus.

These tubes are a temporary measure. They stabilize the patient until bleeding has stopped, blood transfusions are received, and permanent repair is imminent.

Since the lower balloon effectively separates the esophagus from the stomach, it is possible to determine more accurately where the bleeding is located when it is in place.

KEY TERMS

Cholangitis—Inflammation of the system of tubes that drains bile from the liver into the intestines.

Chronic hepatitis—Long lasting inflammation of the liver due to viruses or other causes.

Peptic ulcers—Wounds in the stomach and duodenum caused by stomach acid and the bacterium *Helicobacter pylori*.

Tamponade—To occlude by pressure.

This method of treating upper intestinal bleeding is being replaced by procedures that use a gastroscope, a flexible device that permits viewing and operating without surgery.

Preparation

The procedure is explained to the patient and family. A sedative may be given to prepare the patient for the procedure.

Aftercare

With the tube in place, the patient cannot eat and may have some difficulty breathing. The patient will be hospitalized until the tube can be removed.

Risks

Major complications frequently occur, and **death** results about 3% of the time. Problems include damage to the esophagus and stomach and interference with the airway. Should the tube remain in place too long, there is danger of the pressure eroding the esophagus or the nose.

Tube feedings

Definition

Nutrients, either a special liquid formula or pureed food, are delivered to a patient through a tube directly into the gastrointestinal tract, usually into the stomach or small intestine.

Purpose

Tube feeding provides **nutrition** to patients who are unable or unwilling to eat food. Conditions where tube feeding is considered include **protein-energy malnutrition**, liver or kidney failure, **coma**, or in patients who cannot chew or swallow (dysphagia) due to **stroke**, **brain tumor**, or **head injury**. Patients who are receiving **radiation therapy** or **chemotherapy** treatments for **cancer** may also be candidates for tube feedings.

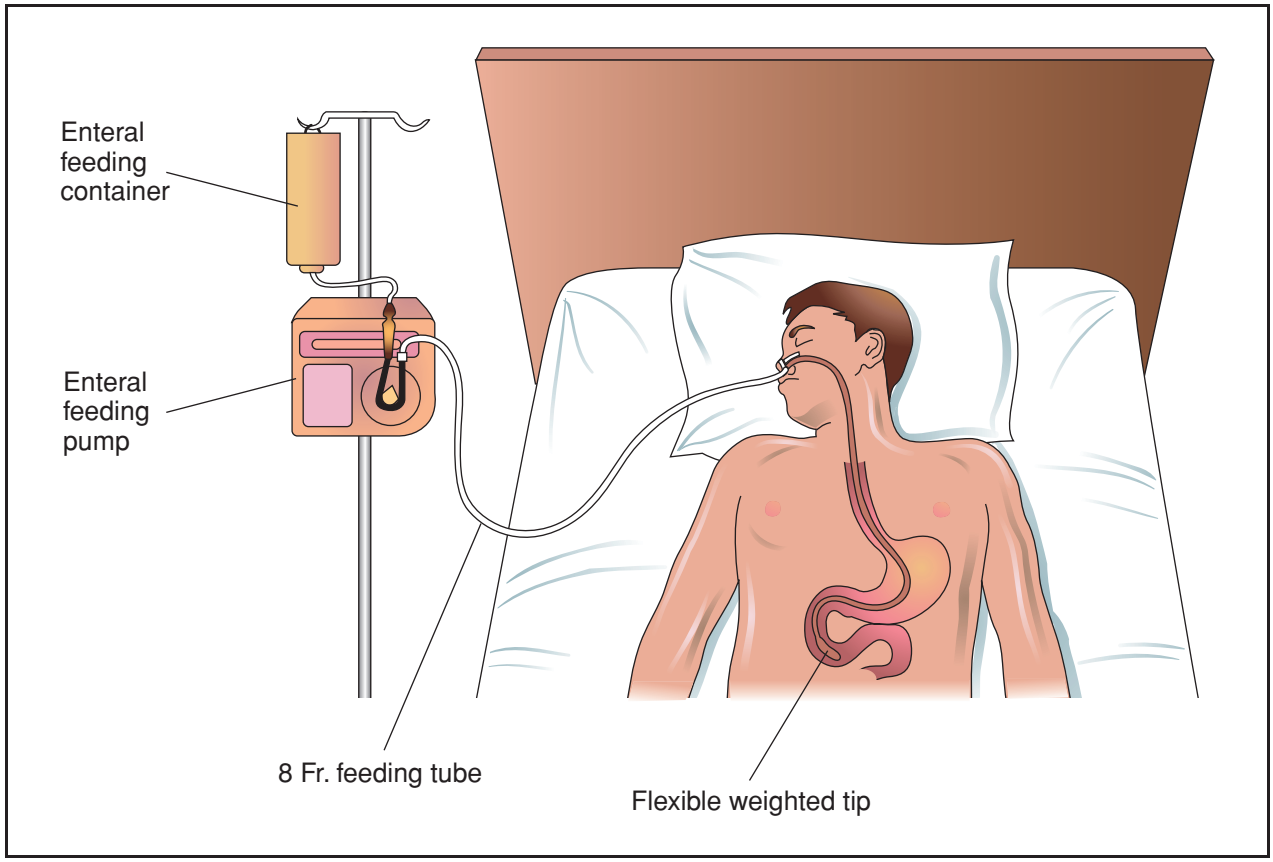
Precautions

Certain medications may interact with some formulas to inactivate the nutrients or change the way that the drug is absorbed.

Description

A flexible, narrow tube is inserted into some portion of the digestive tract and liquid formulas or liquefied foods are placed into the tube to meet the patient's nutritional needs. The feeding may be pumped into the tube or allowed to drip into the tube continuously or at scheduled feeding times.

A feeding tube can be inserted by a surgical or nonsurgical procedure in several positions along the gastrointestinal tract. The tube may be inserted into the nose and passed down the throat and through the esophagus. A nasogastric tube is inserted through the nose with the end of the tube reaching into the stomach. A nasoduodenal or nasojejunal tube is inserted through the nose and ends in either the duodenum or jejunum, both of which are portions of the small intestine. This type of tube placement is usually used for short-term feeding. Surgical placement of a feeding tube may be done if there will be a long-term need for feeding that bypasses the upper digestive tract. An esophagostomy creates an opening in the esophagus, a **gastrostomy** creates an



A feeding tube can be inserted by a surgical or nonsurgical procedure in several positions along the gastrointestinal tract to provide nutrition to patients who are unable or unwilling to eat food. The feeding may be pumped into the tube or allowed to drip into the tube continuously, or at scheduled feeding times. The illustration above features a nasojejunal tube which is inserted through the nose and ends in either the duodenum or jejunum. *(Illustration by Electronic Illustrators Group. Reproduced by permission of Gale, a part of Cengage Learning.)*

KEY TERMS

Duodenum—The upper portion of the small intestine. It is approximately 10 in (25 cm) long and extends from the stomach to the jejunum.

Jejunum—The middle portion of the small intestine. It is approximately 8 ft (2.5 m) long and extends from the jejunum to the ileum.

opening into the stomach, and a jejunostomy creates an opening into the jejunum. The feeding tube is then inserted through the surgically created opening.

Tube feedings can be a mixture of regular foods that are blended with liquid to make a consistency that will pass through the tube. Nutritionally balanced liquid products are often more convenient to use and ensure a balance of proteins, fats, and carbohydrates along with **vitamins** and **minerals**. Specialized formulas are also available to meet almost any nutritional need. For example, patients with severe **burns**, protein-energy **malnutrition**, or slow wound healing may require formulas that are higher in protein. Patients with renal failure may require low-protein formulas with lower concentrations of minerals and vitamins.

Preparation

The reasons that tube feeding is necessary are discussed with the patient, as is the length of time that the feeding tube is expected to be in place. The specific procedure is also explained to the patient.

Aftercare

Patients with **ostomy** feeding tubes may have the tube positioned level with the surrounding skin. A cap or button can be placed over the opening so that it can be more comfortably concealed under clothing. The opening and surrounding tissue need to be cleaned and inspected regularly to prevent infection. For patients with a tube inserted through the nose, daily nasal hygiene is important and the mouth and lips should be kept moist. Good mouth care is necessary for any patient with a feeding tube.

Risks

Formula from the tube can back up in the esophagus and be breathed into the trachea and lungs, causing aspiration **pneumonia**. The placement of the tube should be checked frequently and the head of the bed elevated during and after feeding to prevent the solution from moving back up the digestive tract. Feeding tubes can also become clogged and should be flushed regularly with water. If the feeding formula is too concentrated or given too fast, the patient may experience **nausea**, **vomiting**, cramping, and bloating. The feeding may need to be diluted with liquid or the rate at which it is given decreased. **Diarrhea** or **constipation** can occur if the feeding is not the right composition or does not provide enough liquid. The tube itself can irritate the nasal passage, esophagus, or surrounding tissues.

Normal results

A patient may be able to return to a normal diet of solid foods after short-term supplementation with formula through a feeding tube. In cases where long-term nutritional therapy is required, all of the patient's nutritional needs will have to be provided by the formula. The balance of fluids, calories, proteins, fats, vitamins, and minerals may need to be adjusted periodically.

Abnormal results

If formula feedings are not tolerated by the patient or are inadequate to meet his or her nutritional needs, the patient may need to receive **nutrition through an intravenous line** (parenteral nutrition). This type of therapy involves delivery of sterile nutrient solutions directly into the bloodstream through a needle inserted into a vein.

Tuberculin skin test

Definition

Tuberculosis (TB) is an airborne **infectious disease** caused by the bacterium *Mycobacterium tuberculosis*. Besides culturing in the laboratory, the two most common types of tests to screen for exposure to this disease are the Mantoux PPD tuberculin skin test, which is generally considered more reliable, and the older TB tine test, which is now rarely used. These tests are designed to help identify individuals who may have

been infected by the tuberculosis bacterium. A diagnosis of active, infectious tuberculosis is never made solely based on the results of a TB skin test, but requires further testing, including a **sputum culture** and a chest x-ray.

Purpose

Because TB is spread through the air, especially in poorly ventilated areas, it is more commonly found among people living in crowded conditions, such as jails, nursing homes, and homeless shelters. Often, a TB skin test will be given as part of a **physical examination** when a person is hiring a new employee, particularly for those individuals seeking employment in the health care or food service professions.

People can be exposed to or infected with TB without showing any symptoms or necessarily developing the disease. Individuals with normally functioning immune systems generally prevent the spread of the bacteria by "walling off" or encysting the bacteria within the body. To be at risk for infection a person must have or had close contact with someone who has active tuberculosis (such as a friend or family member). Persons who are more at risk for developing the TB infection overtly include those with a weakened immune system (immunocompromised), either from a chronic disease, such as HIV infection; or as a result of a tissue or organ transplant or other medical treatment designed to suppress the immune system. In addition, persons who are heavy users of crack **cocaine** or alcohol are more susceptible to TB than those who do not abuse these substances. Symptoms of tuberculosis include a persistent **cough**, **fever**, weight loss, night sweats, **fatigue**, and loss of appetite.

Precautions

Although the test is generally considered safe, it is important to inform the person conducting the test if the patient may be pregnant, has had a positive TB test in the past, or has had tuberculosis in the past. People who have had a positive TB test in the past will probably always have a positive test and should not be tested again.

There are several situations when the TB test results might not be accurate. These include situations involving people who:

- have had vaccinations (such as those for measles, polio, rubella or mumps) within the last four weeks
- are taking steroids
- have severe malnutrition

Description

TB skin tests are usually given at a clinic, hospital, or doctor's office. Sometimes the tests are given at schools or workplaces and may be a pre-employment requirement. Many cities provide free TB skin tests and followup care. The Mantoux PPD tuberculin skin test involves injecting a very small amount of a substance called PPD tuberculin just under the top layer of the skin (intracutaneously). Tuberculin is a mixture of antigens obtained from the culture of *M. tuberculosis*. Antigens are foreign particles or proteins that stimulate the immune system to produce antibodies. Two different tuberculin preparations are available, Old Tuberculin (OT) and Purified Protein Derivative (PPD). The latter is the preferred testing substance. The test is usually given on the inside of the forearm about halfway between the wrist and the elbow, where a small bubble will form as the tuberculin is injected. The skin test takes just a minute to administer.

After 48–72 hours, the test site will be examined by a trained person for evidence of swelling. People who have been exposed to tuberculosis will develop an immune response, causing a slight swelling at the injection site. If there is a lump or swelling, the health care provider will use a ruler to measure the size of the reaction. Some public health physicians recommend using a 72-hour waiting period as a general practice on the grounds that a 48-hour waiting period yields a higher percentage of false negative test results.

The other method of TB skin test is called the multiple puncture test or tine test because the small test instrument has several small tines that lightly prick the skin. The small points of the instrument are either coated with dried tuberculin or are used to puncture through a film of liquid tuberculin. The test is read by measuring the size of the largest papule. Because it is not possible to precisely control the amount of tuberculin used in the tine test, a positive test should be verified using the Mantoux test. For this reason, the tine test is not as widely used as the Mantoux test and is considered to be less reliable; it is no longer recommended for general use.

Preparation

There is no special preparation needed before a TB skin test. A brief personal history will be taken to determine whether the person has had tuberculosis or a TB test before, has been in close contact with anyone with TB, or has any significant risk factors. Directly before the test, the skin on the arm at the injection site is usually cleaned with an alcohol swab and allowed to air dry.

Aftercare

After having a TB skin test, it is extremely important to make sure that the patient keeps the appointment to have the test reaction read. The patient is instructed to keep the test site clean, uncovered, and to not scratch or rub the area. Should severe swelling, **itching**, or **pain** occur, or if the patient has trouble breathing, the clinic or health care provider should be contacted immediately.

Risks

The risk of an adverse reaction is very low. Occasionally, an individual who has been exposed to the TB bacteria will develop a large reaction in which the arm swells and is uncomfortable. This reaction should disappear in two weeks. A sore might develop where the injection was given, or a fever could occur, but these are extremely rare reactions.

It is possible that a person who has TB may receive a negative test result (called a "false negative") or a person who does not have TB may receive a positive test result (called a "false positive"). If there is some doubt, the test may be repeated or the person may be given a diagnostic test using a **chest x ray** and/or sputum sample culture test to determine whether the disease is present and/or active in the lungs.

Normal results

In people who have not been exposed to TB, there will be little or no swelling at the test site after 48–72 hours. This is a negative test result. Negative test results can be interpreted to mean that the person has not been infected with the tuberculosis bacteria or that the person has been infected recently and not enough time has elapsed for the body to react to the skin test. Persons become sensitive between two and ten weeks after the initial infection. As a result, if the person has been in contact with someone with tuberculosis, the test should be repeated in three months. Also, because it may take longer than 72 hours for an elderly individual to develop a reaction, it may be useful to repeat the TB skin test after one week to adequately screen these individuals. Immunocompromised persons may be unable to react sufficiently to the Mantoux test, and either a chest x ray or sputum sample may be required.

A newer test that appears to be preferable to the tuberculin skin test in evaluating patients who are HIV-positive is the enzyme-linked immunospot (ELISPOT) assay. A group of researchers in the United Kingdom found that the ELISPOT assay was more accurate than the PPD test in detecting active as well as latent tuberculosis in HIV-positive patients.

KEY TERMS

Antibody—A specific protein produced by the immune system in response to a specific foreign protein or particle called an antigen.

Antigen—Any foreign particle or protein that causes an immune response.

Attenuated—Alive but weakened; an attenuated microorganism can no longer produce disease.

Cross-reaction—A positive reaction that occurs as a result of a person's exposure to other non-tuberculosis bacteria.

Immunocompromised—A state in which the immune system is suppressed or not functioning properly.

Induration—An abnormally hard spot or area on the skin. The tuberculin skin test produces an induration at the test site in persons who have been exposed to TB.

Intracutaneous—Into the skin, in this case directly under the top layer of skin.

Mantoux or PPD test—Other names for a tuberculin skin test. PPD stands for purified protein derivative.

Tuberculin—A mixture of antigens obtained from the cultured bacteria that cause tuberculosis, *Mycobacterium tuberculosis*.

Abnormal results

A reaction of 5 mm of induration (swelling) is considered positive for the following groups:

- household contacts of persons with active tuberculosis
- AIDS patients
- persons with old healed tuberculosis on chest x ray
- organ transplant recipients.
- persons receiving immunosuppressive medications

A reaction of 10 mm of induration is considered positive in individuals with one or more of the following risk factors which are either reasons to have a higher exposure to TB and/or a condition that increases the risk for progression to active TB:

- foreign-born immigrants from Asia, Africa, or Latin America
- injection drug users and persons who abuse alcohol
- residents and employees of such high-risk congregate settings as hospitals, homeless shelters, and jails
- medically under-served low income populations

- TB laboratory personnel
- children younger than four years of age or infants, children or adolescents exposed to adults in high risk categories
- residents of long-term care facilities
- individuals with certain medical conditions that increase the risk of developing tuberculosis; these medical conditions include being 10% or more below ideal body weight, silicosis, chronic renal failure, diabetes mellitus, high dose corticosteroid or other immunosuppressive therapy, some blood disorders like leukemia and lymphomas, and other cancer

Finally, a reaction of 15 mm of induration or greater is considered positive in those with no risk factors and are therefore at the lowest risk of developing TB.

A TB skin conversion is defined as an increase of 10 mm or greater of induration within a two year period, regardless of age.

A positive reaction to tuberculin may be the result of a previous natural infection with *M. tuberculosis*, infection with a variety of non-tuberculosis mycobacteria (cross-reaction), or tuberculosis **vaccination** with a live, but weakened (attenuated) mycobacterial strain. TB vacination is not done in the United States. Cross-reactions are positive reactions that occur as a result of a person's exposure to other non-tuberculosis bacteria. These tend to be smaller than those caused by *M. tuberculosis*. There is no reliable way of distinguishing whether a positive TB skin test is due to a previous vaccination against tuberculosis. Generally, however, positive results are not due to vaccination exposure because reactions in vaccinated people tend to be less than 10 mm, and an individual's sensitivity to tuberculin steadily declines after vaccination. If the skin test is interpreted as positive, a chest x ray will be performed to determine whether the person has active tuberculosis or whether the body has sufficiently handled the infection.

Tuberculosis

Definition

Tuberculosis (TB) is a chronic, potentially fatal contagious disease that most often affects the lungs but can affect other parts of the body. It is caused by a bacterium or tubercle bacillus *Mycobacterium tuberculosis*.

Description

Overview

Tuberculosis was the common disease called consumption until well into the twentieth century. In 1882 when the microbiologist Robert Koch discovered the tubercle bacillus that causes the disease, TB caused one of every seven deaths in Europe. The tubercle bacillus is transmitted when an infected person coughs or sneezes

FLORENCE B. SEIBERT (1897–1991)

(The Library of Congress.)

Florence Barbara Seibert was born on October 6, 1897, in Easton, Pennsylvania, the second of three children. She was the daughter of George Peter Seibert, a rug manufacturer and merchant, and Barbara (Memmert) Seibert. At the age of three she contracted polio. Despite her resultant handicaps, she completed high school, with the help of her highly supportive parents, and entered Goucher College In Baltimore, where she studied chemistry and zoology. She graduated in 1918, then worked under the direction of one of her chemistry teachers, Jessie E. Minor, at the Chemistry Laboratory of the Hammersley Paper Mill in Garfield, New Jersey. She and her professor, having responded to the call for women to fill positions vacated by men fighting in World War I, coauthored scientific papers on the chemistry of cellulose and wood pulps.

A biochemist who received her Ph.D. from Yale University in 1923, Florence B. Seibert is best known for her research in the biochemistry of tuberculosis. She developed the protein substance used for the tuberculosis skin test. The substance was adopted as the standard in 1941 by the United States and a year later by the World Health Organization. In addition, in the early 1920s, Seibert discovered that the sudden fevers that sometimes occurred during intravenous injections were caused by bacteria in the distilled water that was used to make the protein solutions. She invented a distillation apparatus that prevented contamination. This research had great practical significance later when intravenous blood transfusions became widely used in surgery. Seibert authored or coauthored more than a hundred scientific papers. Her later research involved the study of bacteria associated with certain cancers. Her many honors include five honorary degrees, induction into the National Women's Hall of Fame in Seneca Falls, New York (1990), the Garvan Gold Medal of the American Chemical Society (1942), and the John Elliot Memorial Award of the American Association of Blood Banks (1962).

and another person breathes in the infected droplets. The disease is not spread through kissing or other physical contact.

Before **antibiotics** were discovered in the mid-1900s, the only means of controlling the spread of TB was to isolate patients in sanatoriums or hospitals limited to patients with TB. This practice continues today in some countries. The effect of this pattern of treatment was to separate the study of tuberculosis from mainstream medicine. Entire organizations were set up to study not only the disease as it affected individual patients, but also its impact on society. At the beginning of the twentieth century, more than 80% of the population in the United States was infected with TB before age 20, and tuberculosis was the single most common cause of **death**. By 1938 there were more than 700 specialized TB facilities in the United States.

Tuberculosis spread widely in Europe as the result of the industrial revolution in the late nineteenth century when many people moved to towns where they lived in crowded, unsanitary conditions. The disease became widespread somewhat later in the United States. In the early 1940s with the discovery of streptomycin, the first antibiotic effective against *M. tuberculosis*, the infection began for the first time to be contained. Although other more effective anti-tuberculosis drugs that continue to reduce the number of TB cases have been developed in the past half century, reports of active TB cases in the United States began to increase in the mid-1980s. This upsurge was in part a result of overcrowding and unsanitary conditions in the poor areas of large cities, prisons, and homeless shelters. Infected visitors and immigrants to the United States also contributed to the resurgence of TB. An additional factor was the **AIDS** epidemic. Individuals with HIV/AIDS are much more likely to develop tuberculosis because of their weakened immune systems than healthy individuals.

The number of reported TB cases in the United States peaked in 1993 and has since declined. However,

new multi drug-resistant strains of TB (MDR TB) have become a major public health concern. In the mid 2000s, health officials worldwide joined to work at preventing a drug-resistant form of the disease from becoming widespread.

In 2005, the United States Centers for Disease Control and Prevention (CDC) reported a record low number of 14,097 cases of active TB in the United States, of which 55% occurred in foreign-born individuals. However, the rate of multi-drug resistant had increased 13.3% since 2000. The CDC estimated that in 2005 about 10 million people in the United States have latent (symptom-free) TB infections.

The World Health Organization (WHO) estimates that about one-third of the world's population is infected with *M. tuberculosis*. Of those infected, between 5% and 10% will develop active TB. In individuals who have HIV/AIDS infections, the rate is much higher. The greatest number of active TB infections per capita is found in sub-Saharan Africa where AIDS is epidemic. About one-third of infections occur in Southeast Asia. WHO estimates that TB caused about 1.6 million deaths in 2005. Although the rate per capita of active TB is declining worldwide, the absolute number of cases is increasing in many areas because of high population growth.

High-risk populations

THE ELDERLY. Tuberculosis is more common in elderly individuals. More than 60% of cases in the United States are diagnosed in people between the ages of 25–65. About one-quarter of TB cases newly diagnosed occur in people over age 65. Many elderly individuals developed TB after acquiring a latent TB infection years earlier. As they age, their immune systems can no longer control the disease, and they develop active TB symptoms. In addition, elderly people living in nursing homes and other group facilities are often in close contact with others who may be infected.

RACIAL AND ETHNIC GROUPS. Higher rates of TB are found in the non-white population in the United States, but health researchers believe that this likely is related to the socioeconomic status of these groups rather than to race-related biological factors. Individuals of lower socioeconomic status tend to live in more crowded conditions and have less access to health care than higher socioeconomic status individuals, conditions which encourage the infection with *M. tuberculosis*.

As of 2009, TB was a major health problem in the United States among certain immigrant groups that come from countries where TB infection is common. California, New York, Texas, Florida, all states with large immigrant populations, accounted for almost half of all active TB cases. The most common countries of origin for foreign-born persons in the United States with active TB were Mexico, the Philippines, Vietnam, India, and China.

LIFESTYLE FACTORS. The high risk of TB in AIDS patients extends to those infected by human **immunodeficiency** virus (HIV) who have not yet developed clinical signs of AIDS but whose immune systems are weakened by the virus. Other people who take drugs that suppress the immune system (e.g., transplant patients) are also at higher risk of becoming infected, as are people who have **silicosis**, a lung disease. Individuals who are alcoholics, intravenous drug abusers, and the homeless are also at increased risk of contracting tuberculosis.

Causes and symptoms

Transmission

Tuberculosis spreads by droplet infection. When a person infected with *M. tuberculosis* exhales, coughs, or sneezes, tiny droplets of fluid containing tubercle bacilli are released into the air. People in close physical contact with the infected person inhale this fine mist. Tuberculosis is not highly contagious compared to some other infectious diseases. As a rule, close, frequent, or prolonged contact is needed to spread the disease. Most people do not develop TB even when exposed to a person with active TB. Unlike many other infections, TB is not passed on by contact with a an infected individual's clothing, bed linens, dishes or cooking utensils. The disease is not spread through kissing or other physical contact. The most important exception is **pregnancy**. The fetus of an infected mother may contract TB by inhaling or swallowing the bacilli in the amniotic fluid.

Progression

Once a person inhales *M. tuberculosis*, one of four things can happen.

- The person's immune system can kill the bacteria; no TB infection results and the person is not contagious.
- The bacteria can become dormant and never grow; no TB symptoms are seen, and the person is not contagious.
- The bacteria can become dormant for a period, then begin to grow; TB symptoms appear a long time after infection. The person is not contagious during the dormant period, then becomes contagious when symptoms appear.
- The bacteria multiples immediately; active TB symptoms appear and the person is contagious.

At least nine of ten people who are infected with *M. tuberculosis* do not develop symptoms of TB, and

their chest x-rays remain negative. These people have what is called a latent TB infection. They are not contagious; however, they do form a pool of infected individuals who may get sick later and then pass on TB to others. It is thought that more than 90% of cases of active tuberculosis come from this pool. In the United States, there are about 10 million people with latent TB infections. It is impossible to predict which individuals with latent TB infections will develop active TB. An estimated 5% of infected persons get sick within 12–24 months of being infected. Another 5% heal initially but, after years or decades, develop active tuberculosis either in the lungs or elsewhere in the body. On rare occasions, a previously infected person gets sick again after a later exposure to the tubercle bacillus.

Pulmonary tuberculosis

Pulmonary tuberculosis is TB that affects the lungs. Its initial symptoms are easily confused with those of other diseases. An infected person may at first feel vaguely unwell or develop a **cough** that could be blamed on **smoking** or a cold. A small amount of greenish or yellow sputum may be coughed up when the person gets up in the morning. In time, more sputum is produced that is streaked with blood. People who have pulmonary TB do not get a high **fever**, but they often have a low-grade one. The individual often loses interest in food and may lose weight. Chest **pain** is sometimes present. If the infection allows air to escape from the lungs into the chest cavity (**pneumothorax**) or if fluid collects in the pleural space (**pleural effusion**), the patient may have difficulty breathing. If a young adult develops a pleural effusion, the chance of tubercular infection being the cause is very high.

Before the development of effective TB drugs, many patients became chronically ill with increasingly severe lung symptoms. They lost a great deal of weight and developed a wasted appearance, hence the name consumption. This outcome is uncommon today where modern treatment methods are available.

Extrapulmonary tuberculosis

Although the lungs are the major site of damage caused by tuberculosis, other organs and tissues in the body may be affected. The usual progression is for the disease to spread from the lungs to locations outside the lungs (extrapulmonary sites). In occasional cases, however, the first sign of disease appears outside the lungs. The many tissues or organs that tuberculosis may affect include:

- bones. TB is particularly likely to attack the spine and the ends of the long bones. Children are especially prone to spinal tuberculosis. If not treated, the spinal segments (vertebrae) may collapse and cause paralysis in one or both legs.
- kidneys. Along with the bones, the kidneys are the commonest site of extrapulmonary TB. There may, however, be few symptoms even after part of a kidney is destroyed. TB may also spread to the bladder. In men, it may spread to the prostate gland and nearby structures.
- female reproductive organs. The ovaries in women may be infected and TB may spread from them to the peritoneum (the membrane lining the abdominal cavity).
- abdominal cavity. Tuberculosis peritonitis may cause pain ranging from the vague discomfort of stomach cramps to intense pain that may mimic the symptoms of appendicitis.
- joints. Tubercular infection of joints causes a form of arthritis that most often affects the hips and knees. The wrist, hand, and elbow joints also may become painful and inflamed.
- meninges. The meninges are tissues that cover the brain and the spinal cord. Infection of the meninges by the TB bacillus causes tuberculosis meningitis, a condition that is most common in young children but is especially dangerous in the elderly. Patients develop headaches, become drowsy, and eventually, comatose. Permanent brain damage is the rule unless prompt treatment is given. Some patients with tuberculosis meningitis develop a tumor-like brain mass called a tuberculoma that can cause stroke-like symptoms.
- skin, intestines, adrenal glands, and blood vessels. All these parts of the body can be infected by *M. tuberculosis*. Infection of the wall of the body's main artery (the aorta), can cause it to rupture with catastrophic results. Tuberculosis pericarditis occurs when the membrane surrounding the heart (the pericardium) is infected and fills up with fluid that interferes with the heart's ability to pump blood.
- miliary tuberculosis. Miliary TB is a life-threatening condition that occurs when large numbers of tubercle bacilli spread throughout the body. Huge numbers of tiny tubercular lesions develop that cause marked weakness and weight loss, severe anemia, and gradual wasting of the body.

Multi drug-resistant tuberculosis (MDR TB)

In the twenty-first century, there is increasing concern about strains of *M. tuberculosis* that are resistant to the TB drugs that have brought the disease under control in the past half century. MDR TB is TB that fails to

respond to at least two drugs, isoniazid (INH) and rifampin (RIF), that are routinely used to treat TB. In the United States, MDR TB, although rare, is on the rise. The CDC has developed a special group of experts to work with physicians who have MDR TB patients. There is concern that drug-resistant TB could spread widely and cause a public health crisis. When alternate drug therapy fails to control MDR TB, **lung surgery** is the preferred treatment option.

Diseases similar to tuberculosis

There are many forms of mycobacteria other than *M. tuberculosis*, the tubercle bacillus. Some cause infections that may closely resemble tuberculosis, but they usually do so only when an infected person's immune system is defective. This occurs, for example, in some people who are HIV-positive. The most common mycobacteria that infect HIV/AIDS patients are a group known as *Mycobacterium avium* complex (MAC). People infected by MAC are not contagious, but they may develop a serious lung infection that is highly resistant to antibiotics. MAC infections typically start with the patient coughing up mucus. The infection progresses slowly, but eventually blood is brought up in the sputum, and the patient has trouble breathing. In HIV/AIDS patients, MAC disease can spread throughout the body, with anemia, **diarrhea**, and stomach pain as common symptoms. Often these patients die unless their immune system can be strengthened. Other mycobacteria grow in swimming pools and may cause skin infection. Some of them infect **wounds** and artificial body parts such as a **breast implants** or mechanical heart valves.

Diagnosis

The standard screening test for tuberculosis is the **tuberculin skin test**. This test detects the presence of infection, not of active TB. Tuberculin is an extract prepared from cultures of *M. tuberculosis*. It contains proteins belonging to the bacillus (antigens) to which an infected person has been sensitized. When tuberculin is injected into the skin of an infected person, the area around the injection becomes hard, swollen, and red within one to three days.

Skin tests use a substance called purified protein derivative (PPD) that has a standard chemical composition and is therefore is a good measure of the presence of tubercular infection. The PPD test is also called the Mantoux test. The Mantoux PPD skin test is not, however, 100% accurate; it can produce false positive as well as false negative results. In other words, some people who have a skin reaction are not infected (false positive) and some who do not react are in fact infected (false negative). The PPD test is, however, a highly useful screening test and is required in most states for children to enter school. In addition, anyone who has suspicious findings on a **chest x ray**, or any condition that makes TB more likely should have a PPD test, as should people who are in close contact with a TB patient, those who come from a country where TB is common, and all healthcare personnel as well as persons living or working in institutions such as prisons.

To verify the test results, the physician will do a chest x ray and obtain a sample of sputum or a tissue sample (biopsy) for culture. Three to five sputum samples should be taken early in the morning. Culturing *M. tuberculosis* is useful for diagnosis because the bacillus has certain distinctive characteristics. Unlike many other types of bacteria, mycobacteria can retain certain dyes even when exposed to acid. This acid-fast property is characteristic of the tubercle bacillus.

Body fluids other than sputum can be used for a TB culture. If TB has invaded the brain or spinal cord, culturing a sample of spinal fluid will make the diagnosis. If TB of the kidneys is suspected because of pus or blood in the urine, culture of the urine may reveal tubercular infection. Infection of the ovaries in women can be detected by inserting a tube having a light on its end (a laparoscope) into the area. Samples also may be taken from the liver or bone marrow to detect the tubercle bacillus.

For most people, a simple skin test is adequate to screen for TB. However, new advances in the diagnosis of TB use molecular techniques to speed the diagnostic process as well as improve its accuracy. As of 2007, molecular testing is being used more frequently in laboratories around the world. Molecular tests include a polymerase chain reaction to detect mycobacterial DNA in patient specimens; nucleic acid probes to identify mycobacteria in culture; restriction fragment length polymorphism analysis to compare different strains of TB for epidemiological studies; and genetic-based susceptibility testing to identify drug-resistant strains of mycobacteria.

Treatment

Supportive care

In the past, treatment of TB was primarily supportive. Patients were kept in **isolation**, encouraged to rest, and fed well. If these measures failed the lung was collapsed surgically so that it could "rest" and heal. Today surgical procedures still are used when necessary, but contemporary medicine relies on drug therapy as the mainstay of care. Given an effective combination of

drugs, many patients with TB can be treated at home rather than in a sanatorium.

Drug therapy

Most patients with TB recover if given appropriate medication for a sufficient length of time. Three principles govern modern drug treatment of TB.

- Lowering the number of bacilli as quickly as possible. This minimizes the risk of transmitting the disease. When sputum cultures become negative, this has been achieved. Conversely, if the sputum remains positive after five to six months, treatment has failed.
- Preventing the development of drug resistance. For this reason, at least two different drugs and sometimes up to four are always given as initial treatment.
- Long-term treatment to prevent relapse.

Five drugs are most commonly used treat tuberculosis: isoniazid (INH, Laniazid, Nydrazid); rifampin (Rifadin, Rimactane); pyrazinamide (Tebrazid); streptomycin; and ethambutol (Myambutol). The Centers for Disease Control and Prevention (CDC) and the American Thoracic Society have developed standard regimens for treating TB in an effort to prevent the spread of drug resistant strains. For lung infections in non-immunocom promised people, the disease is usually treated with a regimen of rifampin and isoniazid (INH) for six months, supplemented in the first two months with pyrazinamide and sometimes ethambutol (or streptomycin in very young children). Because some strains of the disease are highly drug-resistant, cultures are grown from the patient's bacteria and tested with a variety of drugs to determine the most effective treatment, and alternate regimens may be determined to be more appropriate.

Except in cases of MDR TB, prolonged hospitalization is rarely necessary because most patients are no longer infectious after about two weeks of combination treatment. Follow-up involves monitoring of side effects and monthly sputum tests. Of the five medications, INH is the most frequently used drug for both treatment and prevention. Hospitalization, isolation, and infectious control measures are required for individuals with MDR TB, which is a very serious disease both for the individual and from a public health standpoint. Most states have laws that allow individuals with TB to be hospitalized against their will for non-compliance with treatment.

Surgery

Surgical treatment of TB may be used if drugs fail to control the disease. There are three surgical treatments for pulmonary TB: pneumothorax, in which air is introduced into the chest to collapse the lung; thoracoplasty, in which one or more ribs are removed; and removal of a diseased lung, in whole or in part. Removal is usually required in the case of MDR TB. Individuals can survive with one healthy lung. Extrapulmonary TB may result in the need for other surgeries.

KEY TERMS

Bacillus Calmette-Guérin (BCG)—A vaccine made from a weakened bacillus similar to the tubercle bacillus, which may help prevent serious pulmonary TB and its complications.

Mantoux test—Another name for the PPD test.

Miliary tuberculosis—The form of TB in which the bacillus spreads through all body tissues and organs, producing many thousands of tiny tubercular lesions. Miliary TB is often fatal unless promptly treated.

Mycobacteria—A group of bacteria that includes *Mycobacterium tuberculosis*, the bacterium that causes tuberculosis, and other forms that cause related illnesses.

Pneumothorax—Air inside the chest cavity, which may cause the lung to collapse. Pneumothorax is both a complication of pulmonary tuberculosis and a means of treatment designed to allow an infected lung to rest and heal.

Purified protein derivative (PPD)—An extract of tubercle bacilli that is injected into the skin to find out whether a person presently has or has ever had tuberculosis.

Sputum—Secretions produced in the lung and coughed up. A sign of illness, sputum is routinely used as a specimen for culturing the tubercle bacillus in the laboratory.

Tuberculoma—A tumor-like mass in the brain that sometimes develops as a complication of tuberculosis meningitis.

Prognosis

Most patients recover from TB if the disease is diagnosed early and given prompt treatment with appropriate medications on a long-term regimen. The relapse rate is less than 4%. The exception is for those with MDR TB. When TB is multi drug-resistant, the prognosis depends largely on the ability to surgically remove all infected tissue. The outcome of surgery depends on where and how widespread the infected area is. Miliary tuberculosis is still fatal in many cases but is rarely seen today in developed countries.

Prevention

General measures

General measures such as avoidance of overcrowded and unsanitary conditions are one aspect of prevention. Hospital emergency rooms and similar locations can be treated with ultraviolet light, which has an antibacterial effect. Regular skin testing is required in some jobs and of most children when they enter school and often again if when enter college. Although screening does not prevent TB, it allows early treatment of those who are infected, reducing the likelihood that they will spread the disease.

Vaccination

Vaccination is a preventive measure against TB. A vaccine called BCG (Bacillus Calmette-Guérin, named after its French developers) is made from a weakened mycobacterium that infects cattle. Vaccination with BCG does not prevent infection by *M. tuberculosis,* but it does strengthen the immune system response and provide partial protection. BCG is used more widely in developing countries than in the United States. The effectiveness of vaccination is still being studied; it is not clear whether the vaccine's effectiveness depends on the population in which it is used or on variations in its formulation.

In 2007, the first new TB vaccine in 80 years was in clinical trials in South Africa. The new vaccine known as MVA85A, was developed at Oxford University, England, in response to increasing concern about the rise of MDR TB. This vaccine works with BCG vaccine to increase its effectiveness and produce a very strong immune system response. In 2007, clinical trials were focusing on whether the new vaccine actually prevents the disease. Makers of the vaccine predict that even if clinical trials are successful, the vaccine will not be available on the market until about 2015.

Prophylactic use of isoniazid

INH can be given for the prevention as well as the treatment of TB. INH is effective when given daily over a period of six to 12 months to people in high-risk categories. INH appears to be most beneficial to persons under the age of 25. Because INH carries the risk of side effects (liver inflammation, nerve damage, changes in mood and behavior) in about one-fifth of people taking the drug, it is important to give it only to persons at special risk. The increase in MDR TB is also causing some TB experts to re-evaluate preventative drug treatment.

High-risk groups for whom isoniazid prevention may be justified include:

- close contacts of TB patients, including health care workers
- newly infected patients whose skin test has turned positive in the past two years
- anyone who is HIV-positive with a positive PPD skin test; Isoniazid may be given even if the PPD results are negative if there is a risk of exposure to active tuberculosis
- intravenous drug users, even if they are negative for HIV
- persons with positive PPD results and evidence of old disease on the chest x-ray who have never been treated for TB
- patients who have an illness or are taking a drug that can suppress the immune system
- persons with positive PPD results who have had intestinal surgery; have diabetes or chronic kidney failure; have any type of cancer; or are more than 10% below their ideal body weight
- people from countries with high rates of TB who have positive PPD results
- people from low-income groups with positive skin test results
- persons with a positive PPD reaction who belong to high-risk ethnic groups (African Americans, Hispanics, Native Americans, Asians, and Pacific Islanders)
- householders who have lived with someone who has been diagnosed with an active TB infection.

Tularemia

Definition

Tularemia is an illness caused by a bacterium. It results in **fever**, rash, and greatly enlarged lymph nodes.

Description

Tularemia infects a variety of wild animals, including rabbits, deer, squirrels, muskrat, and beaver. Humans can acquire the bacterium directly from contact with the blood or body fluids of these animals, from the bite of a tick or fly which has previously fed on the blood of an infected animal, or from contaminated food or water.

Tularemia occurs most often in the summer months. It is most likely to infect people who come into contact with infected animals, including hunters, furriers, butchers, laboratory workers, game wardens, and veterinarians. In the United States, the vast majority of cases of tularemia occur in the southeastern and Rocky Mountain states.

Causes and symptoms

Five types of illness may occur, depending on where/how the bacteria enter the body:

- Ulceroglandular/glandular tularemia. Seventy-five to 85% of all cases are of this type. This type is contracted through the bite of an infected tick that has defecated bacteria-laden feces in the area of the bite wound. A tender red bump appears in the area of the original wound. Over a few weeks, the bump develops a punched-out center (ulcer). Nearby lymph nodes grow hugely swollen and very tender. The lymph nodes may drain a thick, pus-like material. Other symptoms include fever, chills, and weakness. In adults, the lymph nodes in the groin are most commonly affected; in children, the lymph nodes in the neck.
- Oculoglandular tularemia. This type accounts for only about 1% of all cases of tularemia. It occurs when a person's contaminated hand rubs his or her eye. The lining of the eyelids and the surface of the white of the eye (conjunctiva) becomes red and severely painful, with multiple small yellow bumps and pitted sores (ulcers). Lymph nodes around the ears, under the jaw, or in the neck may swell and become painful.
- Oropharyngeal and gastrointestinal tularemia. This type occurs when contaminated meat is undercooked and then eaten, or when water from a contaminated source is drunk. Poor hygiene after skinning and cleaning an animal obtained through hunting can also lead to

KEY TERMS

Conjunctiva—The lining of the eyelids and the surface of the white part of the eye.

Shock—A state in which drastically low blood pressure prevents adequate blood flow to the tissues and organs throughout the body.

the bacteria entering through the mouth. Sores in the mouth and throat, as well as abdominal pain, nausea and vomiting, ulcers in the intestine, intestinal bleeding, and diarrhea may all occur.

- Pulmonary tularemia. This rare type of tularemia occurs when a person inhales a spray of infected fluid, or when the bacteria reach the lungs through the blood circulation. A severe pneumonia follows.
- Typhoidal tularemia. This type of tularemia is particularly hard to diagnose, because it occurs without the usual skin manifestations or swelling of lymph glands. Symptoms include continuously high fever, terrible headache, and confusion. The illness may result in a severely low blood pressure, with signs of poor blood flow to the major organs (shock).

Diagnosis

Samples from the **skin lesions** can be prepared with special stains, to allow identification of the causative bacteria under the microscope. Other tests are available to demonstrate the presence of antibodies (special immune cells that the body produces in response to the presence of specific foreign invaders) which would be increasing over time in an infection with tularemia.

Treatment

Streptomycin (given as a shot in a muscle) and gentamicin (given as either a shot in a muscle or through a needle in the vein) are both used to treat tularemia. Other types of **antibiotics** have been tested, but have often resulted in relatively high rates of relapse (20%).

Prognosis

With treatment, **death** rates from tularemia are under 1%. Without treatment, however, the death rate may reach 30%. The **pneumonia** and typhoidal types have the worst prognosis without treatment.

Prevention

Prevention involves avoiding areas known to harbor ticks and flies, or the appropriate use of insect repellents. Hunters should wear gloves when skinning animals or preparing meat. Others (butchers, game wardens, veterinarians) who work with animals or carcasses should always wear gloves. A vaccine exists, but is usually only given to people at very high risk due to their profession or hobby (veterinarians, laboratory workers, butchers, hunters, game wardens).

Tumor markers

Definition

Tumor markers are measurable biochemicals that are associated with a malignancy. They are either produced by tumor cells (tumor-derived) or by the body in response to tumor cells (tumor-associated). They are typically substances that are released into the circulation and thus measured in the blood. There are a few exceptions to this, such as tissue-bound receptors that must be measured in a biopsy from the solid tumor or proteins that are secreted into the urine.

Purpose

Though tumor markers are rarely specific enough to be used alone to diagnose **cancer**, they do have a number of clinical uses. They can be used to stage cancer, to indicate a prognosis, to monitor treatment, or in follow-up to watch for cancer recurrence. Changes in some tumor markers have been sensitive enough to be used as targets in clinical trials. When used for diagnosis, tumor markers are used in conjunction with other clinical parameters such as biopsy and radiological findings. Although there are a multitude of tumor markers, very few of them have found their way into clinical practice because of their lack of specificity. However, some of these non-specific markers have found a place in monitoring cancer treatment rather than in diagnosis.

Description

As tumor cells grow and multiply, some of their substances can increase and leak into the bloodstream or other fluids. Depending upon the tumor marker, it can be measured in blood, urine, stool or tissue. Some widely used tumor markers include: AFP, beta-HCG, CA 15-3, CA 19-9, CA 27-29, CA 125, CEA, and PSA. Some

tumor markers are associated with many types of cancer; others, with as few as one. Some tumor markers are always elevated in specific cancers; most are less predictable. However, no tumor marker is specific for cancer and most are found in low levels in healthy persons, or can be associated with non-neoplastic diseases as well as cancer. Also, no tumor marker test is free of false negatives or false positives.

Once cancer is diagnosed, tumor marker levels sometimes help to determine the extent of cancer. Higher levels can indicate more advanced cancer and a worse prognosis in some cases. Patients and their physician may use this information to choose between more or less aggressive treatments.

Monitoring cancer treatment is the most common use of tumor markers. As cancer is reduced, levels often decrease. Stable or increasing levels often indicate that the cancer is not responding to treatment. The choice of tumor marker to use for monitoring is important. Only a marker elevated before treatment should be used to monitor a person during or after treatment. Timing of the tests is also important. Each tumor marker has a unique life span in the blood. To monitor a treatment's success, enough time must have passed for the initial marker to be cleared from the blood. Tests done too soon may be falsely elevated because the marker produced by the untreated cancer is still present.

Watching for cancer recurrence after treatment is another reason for tumor marker testing. Periodic testing can sometimes detect a recurrence often months earlier than could an ultrasound, x ray, or **physical examination**.

Tumor marker tests are performed in a lab using immunological techniques. A sample of blood or other tissue is mixed with a substance containing specific antibodies to each tumor marker. If that tumor marker is present, these very specific antibodies bind to the markers. Some type of label, often a radioactive substance, is then used to measure the amount of bound marker and antibody. From this measurement, the amount of tumor marker is calculated. The results are usually available within a few days.

Conclusions based on tumor marker tests are seldom based on one test result but on a series of test results, called serial measurements. A series of increasing or decreasing values is more significant than a single value.

Tumor marker testing is currently the object of much research and attention. Their use is directed by approval from the Food and Drug Administration (FDA) and guidelines established by organizations such as the American Society of Clinical Oncology and the American Cancer Society. Not all tumor receptor marker tests are widely available nor are they widely accepted.

Oncofetal antigens

There are two common oncofetal antigens, alpha-fetoprotein (AFP) and carcinoembryonic antigen (CEA). Carcinoembryonic antigen CA 72-4 is a more recently discovered oncofetal antigen just coming into usage. The oncofetal antigens are so named because they are normally produced during embryonic development and decrease soon after birth. Cancer cells tend to dedifferentiate, or revert to a more immature tissue and begin to produce fetal antigens again. Oncofetal antigens are very non-specific and expressed by a wide number of cancer types. However, they are used both to monitor a patient's progress and their response to treatment over time.

ALPHA-FETOPROTEIN (AFP). Elevated AFP typically indicates a primary liver tumor or a germ cell tumor of the ovary or testicle. AFP is a glycoprotein produced in high amounts by fetal tissue and is elevated during **pregnancy**. It is most widely used as a marker for hepatocellular carcinoma and **testicular cancer** but is also associated with **ovarian cancer**. Seventy percent of people with **liver cancer** have increased AFP levels. In China, where liver cancer rates are high, AFP is used as a screening test for that disease. AFP levels indicate the extent of cancer, and serial measurements are used to monitor treatment response. Non-cancerous liver conditions such as **cirrhosis** and hepatitis have moderately increased levels of AFP.

CARCINOEMBRYONIC ANTIGEN (CEA). CEA is a glycoprotein most often associated with colorectal cancer, and used to monitor patients with this type of cancer. Its most popular use is in early detection of relapse in individuals already treated for colorectal cancer. After surgery, serial measurements indicate the surgery's success and are used to detect early signs of recurrence. It has recently been found to be useful when measured during surgery for colorectal cancer to help determine prognosis and who will benefit from adjuvant treatment.

CEA is measured in the blood plasma. It is very nonspecific and can be increased in many types of cancer: gastrointestinal, colorectal, ovarian, bladder, cervical, stomach, kidney, lung, pancreatic, liver, prostate, thyroid, melanoma, lymphoma, and breast. People with noncancerous conditions, such as cirrhosis or peptic disease, or inflammatory intestinal conditions such as **colitis** or **diverticulitis**, may also have increased levels. CEA levels can be elevated in elderly patients and in those who smoke.

CANCER ANTIGEN 72-4 (CA 72-4). The more recently identified carcinoembryonic protein is CA 72-4. Although it is slightly elevated with most carcinomas, it is mostly associated with gastric carcinoma (**stomach cancer**). CA 74-2 is finding a role in the management of patients with gastric carcinoma.

Cancer antigen 15-3 (CA 15-3)

CA 15-3 is produced by cells in the breast and increased levels can be associated with **breast cancer**. Rarely increased in women with early breast cancer, it may be used to detect recurrence of cancer in women following treatment or **mastectomy** and to monitor treatment for women with advanced breast cancer. However, adenocarcinomas of the ovary, lung, colon, and pancreas also express elevated CA 15-3 levels. Non-cancerous conditions sometimes associated with elevated CA 15-3 include benign breast or ovarian disease, **endometriosis**, **pelvic inflammatory disease**, and hepatitis. Pregnancy and **lactation** are also related to high CA 15-3 levels.

Cancer antigen 27-29 (CA 27-29)

CA 27-29, also called breast carcinoma-associated antigen, is used as a marker for breast cancer. Eighty percent of women with breast cancer have an increased CA 27-29 level. This marker may be used with other procedures and tumor marker levels such as CA 15-3 to check for recurrences of cancer in previously treated women. Serial measurements monitor treatment response and identify recurrence.

Levels of CA 27-29 may also be increased in cancers of the colon, stomach, kidney, lung, ovary, pancreas, uterus, and liver. Noncancerous conditions associated with elevated CA 27-29 include first trimester pregnancy, endometriosis, **ovarian cysts**, non-cancerous breast disease, **kidney disease**, and **liver disease**.

HER-2/neu

HER-2/neu is an oncogenic growth factor receptor also known as c-erbB-2. It is measured in the tissue from a biopsy either by immunological assays of the protein or polymerase chain reaction (PCR) to identify the DNA. The presence of HER-2/neu is generally associated with a poorer prognosis for breast cancer. It can also help to determine treatment options, since newer drugs can block this protein and decrease cancer growth. The most widely known of these drugs is trastuzumab (brand name Herceptin).

Estrogen receptor

Measurement of the estrogen receptor (ER) is used specifically to evaluate breast cancers. It gives an indication of prognosis and responsiveness to therapy. Tissue from a biopsy is used to measure the estrogen receptor. Most breast cancers in post-menopausal women are ER-positive, meaning that they require estrogen to grow. These ER positive breast cancers are less aggressive than ER negative breast cancers, which are found generally in pre-menopausal women.

Cancer antigen 125 (CA 125)

Although produced by a number of cell types, CA 125 is primarily produced by ovarian cancer cells. Eighty percent of women with ovarian cancer have increased CA 125 levels. Although the test is not sensitive or specific enough to be used for screening, it contributes to a diagnosis when combined with an ultrasound and pelvic examination. Blood levels of CA 125 are used primarily to monitor the treatment of ovarian cancer. A falling CA 125 level usually indicates that cancer is responding to the treatment. After diagnosis and treatment, serial measurements help detect remaining or recurrent cancer. A negative or normal result, however, does not guarantee the absence of cancer.

Women may have increased CA 125 levels during menstruation and pregnancy. Increased levels are also found in pelvic inflammatory disease, endometriosis, **pancreatitis**, and liver disease. Elevated levels are also associated with non-ovarian cancers including cancers of the uterus, cervix, pancreas, liver, colon, breast, lung, or digestive tract.

Prostate specific antigen (PSA)

Prostate specific antigen (PSA) levels, along with the **digital rectal examination**, are used to screen for **prostate cancer**. PSA is a protein produced by the prostate gland and can be overproduced in prostate cancer. It is perhaps the best tumor marker in use because of its tissue specificity, meaning that it is produced only by the prostate. Men over the age of 50 years are advised to consider annual screening for prostate cancer. Men at high risk for prostate cancer, such as African Americans or those with a family history of the disease, should begin screening at age 40. Once a diagnosis of prostate cancer is made, PSA levels can help determine the stage of the cancer, monitor the response to treatment, and watch for recurrence.

Measurements of PSA following **prostatectomy** are useful in determining the success of surgery. Any PSA level following surgery would indicate residual prostate tissue, possibly from metastasis. PSA levels can also be used to detect a recurrence of prostate cancer. PSA is also increased in benign prostatic

hyperplasia (BPH), an **enlarged prostate** condition common in older men.

PSA can be found in the serum in two states, bound and free. Measuring both PSA levels can provide more specificity to the test and reduce unnecessary biopsies. The percentage of free PSA is greater in BPH than prostate cancer. If the total PSA level is higher than 4.0 nanogram/milliliter (ng/mL) and the free PSA level is less than 25%, a **prostate biopsy** is indicated.

PSA levels may increase after ejaculation. Men are recommended to abstain from sexual intercourse or masturbation for 48 hours before the test. PSA levels may also increase after prostate manipulation following the digital rectal exam.

Prostatic acid phosphatase (PAP) was originally found to be produced by the prostate and thought to be a marker for prostate cancer. It is now found to be elevated with testicular cancer, leukemia, non-Hodgkin's lymphoma and several noncancerous conditions.

Cancer antigen 19-9 (CA 19-9)

CA 19-9 has been identified in patients with digestive tract or intra-abdominal carcinomas such as colorectal cancer, pancreatic cancer, stomach cancer and **bile duct cancer**. In pancreatic cancer, higher levels are associated with more advanced disease. After diagnosis, levels help predict the success of surgery and monitor the course of the cancer. Not all people with pancreatic cancer have increased CA 19-9 levels. This antigen is related to the Lewis blood group and so only patients positive for the Lewis blood group antigen will test positive for CA 19-9. It is also increased in liver and gastrointestinal cancers and in noncancerous diseases, including pancreatitis, **gallstones** and **jaundice**.

Human chorionic gonadotropin (hCG)

Human chorionic gonadotropin is normally produced by the placenta during pregnancy. There are two protein subunits that make up HCG, beta and alpha. It is the beta subunit that is increased in women's serum during early pregnancy. It is also the beta subunit that is increased in some malignant tumors. Tumors that secrete beta-hCG are typically **germ cell tumors** such as teratocarcinomas. These are tumors found in the ovaries and testes that contain embryonal tissue. Rarely, these types of tumors are found in the pineal region of the brain where beta-hCG can serve as a marker. Levels of hCG rise with **choriocarcinoma** and with trophoblastic disease, a rare cancer that develops from an abnormally fertilized egg. Gestational trophoblastic tumors also secrete AFP and this test is often used in combination.

HCG is most often used to screen for cancer of the testis or ovary. Serial measurements monitor the progress and treatment of these cancers. This marker can be elevated in individuals who use **marijuana**.

Squamous cell carcinoma (SCC) Antigen

Squamous cell carcinoma (SCC) antigen was first identified in **cervical cancer**. It is a marker for squamous cell cancers, which can occur in the cervix, head and neck, lung, and skin. Levels of SCC can be used as an aid to stage the carcinoma and to determine the response to treatment.

Bence-Jones protein

Patients with plasmacytomas such as myeloma overproduce monoclonal immunoglobulins, also called M proteins. The Bence-Jones protein refers to the immunoglobulin light chain, a portion of these immunoglobulins. The Bence-Jones protein is secreted into the urine where it can be measured. It was the first tumor marker identified.

Neuron-specific enolase (NSE)

NSE is a protein found mainly in neurons and neuroendocrine cells. It is elevated in tumors derived from these tissues, including **neuroblastoma** and **small cell lung cancer**. It can give information about the extent of the disease, the patient's prognosis and the patient's response to treatment. NSE can also be elevated in medullary thyroid cancers, carcinoid tumors, pancreatic endocrine tumors, and melanoma.

Hormone assays

Tumors of the endocrine glands oversecrete their corresponding hormones. By measuring particular hormones, clues can be obtained regarding certain cancers. For instance, breast cancer cells may secrete prolactin and estrogen. Medullary carcinoma can secrete calcitonin. Pheochromocytomas secrete catecholamines. Tumors of the pituitary gland may secrete growth hormone or cortisol. Carcinoid tumors secrete serotonin. Some tumors of the pancreas secrete insulin. Serial measurements can also monitor treatment for these tumors.

Enzymes

Several serum enzymes can be measured to help detect metastases in cancer patients. Tumors that metastasize to the liver cause increases in serum alkaline phosphatase, gamma-glutamyltransferase, and transaminases. Although these are not necessarily tumor markers, they indicate liver damage that may be caused by metastatic cancer. Tumors that metastasize to the

KEY TERMS

AFP (Alpha-fetoprotein)—A tumor marker associated with liver, testicular, and ovarian cancer.

Beta-HCG (Beta-human chorionic gonadotropin)—A tumor marker associated with testicular cancer and tumors, such as choriocarcinoma and molar pregnancies, that begin in placental cells called trophoblasts.

Biopsy—The process of taking a sample of tumor tissue through a needle.

CA 15-3 (Cancer antigen 15-3)—A tumor marker associated with breast cancer.

CA 19-9 (Cancer antigen 19-9)—A tumor marker associated with pancreatic cancer.

CA 27-29 (Breast carcinoma-associated antigen)—A tumor marker associated with breast cancer.

CA 125 (Cancer antigen 125)—A tumor marker associated with ovarian cancer.

CEA (Carcinoembryonic antigen)—A tumor marker associated with many cancers, especially liver, intestinal, and pancreatic.

Prognosis—The predicted outcome of a disease.

PSA (Prostate specific antigen)—A tumor marker associated with prostate cancer.

Sensitivity—A test's ability to detect all cases of a disease.

Serial measurements—A series of measurements looking for an increase or decrease over time.

Specificity—A test's ability to detect only the disease in question.

Tumor markers—Biochemicals produced by tumor cells or by the body in response to tumor cells. Their levels in the blood help evaluate people for certain kinds of cancer.

bone sometimes secrete elevated alkaline phosphatase. Lactate dehydrogenase is an enzyme found throughout the body. Because of this it cannot be used as a marker for cancer. It can, however, be used to monitor the treatment of some types of cancer including germ cell tumors, testicular cancer, Ewing's sarcoma, non-Hodgkins lymphoma and some types of leukemia.

Precautions

There is not a good consensus in the medical community about the value of most tumor markers. Because they lack specificity and accuracy, their use is limited. False positives can cause emotional distress and fear. It is not yet determined if there is a savings of life or money with testing. Currently, much controversy surrounds the issue of mass screening for cancer using tumor markers.

Preparation

Tumor marker tests usually require 5-10 mL of blood. A healthcare worker ties a tourniquet on the patient's upper arm, locates a vein in the inner elbow region, and inserts a needle into that vein. Vacuum action draws the blood through the needle into an attached tube. Collection of the sample takes a few minutes and results are available within a few days.

Some markers, such as those for **bladder cancer**, **multiple myeloma**, and plasmacytomas, are measured in the urine. Typically this requires a 24-hour urine sample, which means that the individual must collect all of his or her urine for 24 hours. This is usually about 1.5 quarts or more. These results are then available within a few days.

Other tumor markers require tissue samples for analysis. These include receptor analysis such as estrogen receptor and Her-2/neu. Tissue samples are obtained by biopsy. This is usually done by inserting a needle through the skin and into the tumor. The area is typically numbed prior to the procedure. These results are also available within two to three days.

Aftercare

Discomfort or bruising may occur at the puncture site or the person may feel dizzy or faint. Pressure to the puncture site until the bleeding stops reduces bruising. Warm packs to the puncture site relieve discomfort. There is a rare chance of infection occurring especially after biopsy. Any sign of infections should be watched for such as **pain** and redness.

Normal results

- AFP: 99% of (nonpregnant) people have less than 15 ng/mL; 95% have less than 6 ng/mL. Serum AFP levels higher than 400 micrograms/L are associated with cancer or some other pathology.

- Beta-HCG: in males, less than 2.5 IU/L; in females, less than 5.0 IU/L; in postmenopausal females, less than 9.0 IU/L.
- CA 15-3: less than 40 U/mL.
- CA 19-9: less than 40 U/mL.
- CA 27.29: less than or equal to 38 U/mL.
- CA 125: less than 35 U/L.
- CEA: less than or equal to 5 ng/mL.
- PSA: less than 4 ng/mL; PSA levels increase with age. Age-specific values range from 2.0 micrograms/L at age 40 to 7.2 micrograms/L at age 80. Typically, levels below 4.0 micrograms/L rule out prostate cancer.

Abnormal results

The meaning of an increased tumor marker level depends on the specific marker, the person's medical history, and why the test was done. Knowledge of the patient's history and additional tests and physical examinations are needed to correctly interpret tumor marker test results.

Tumor removal

Definition

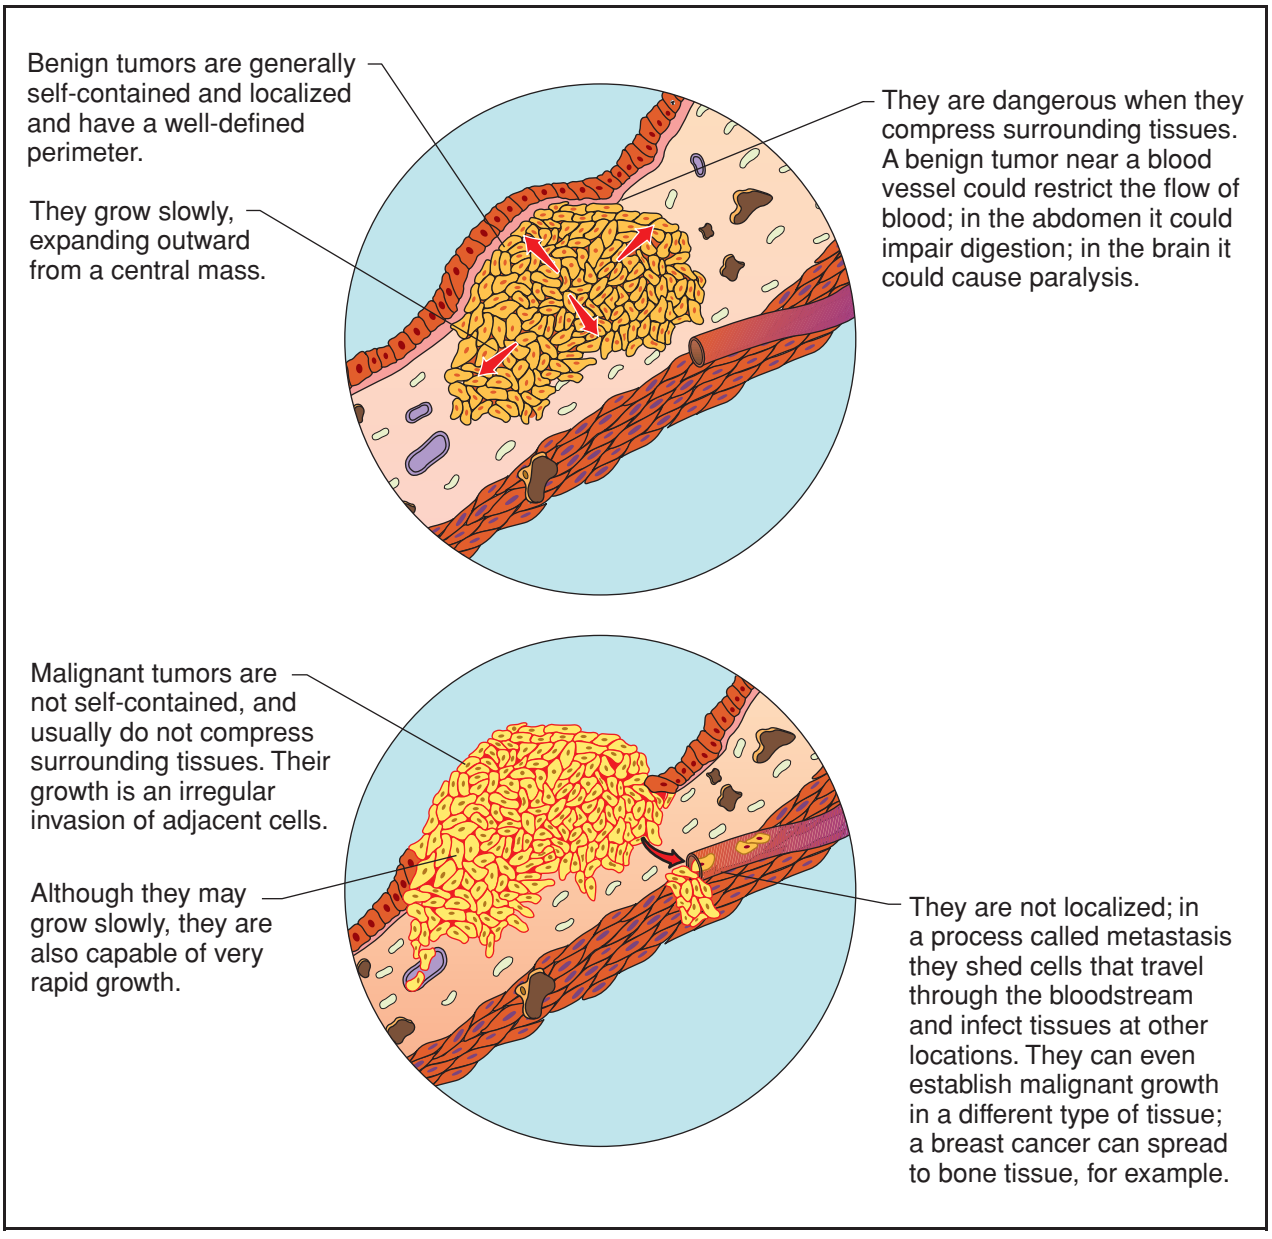
A tumor is an abnormal growth in the body that is caused by the uncontrolled division of cells. Benign tumors do not have the potential to spread to other parts of the body (a process called metastasis) and are curable by surgical removal. Malignant or cancerous tumors, however, may metastasize to other parts of the body and will ultimately result in **death** if not successfully treated by surgery and/or other methods.

Purpose

Surgical removal is one of four main ways that tumors are treated; the other treatment options include **chemotherapy**, **radiation therapy**, and biological therapy. There are a number of factors used to determine which methods will best treat a tumor. Because benign tumors do not have the potential to metastasize, they are often treated successfully with surgical removal alone. Malignant tumors, however, are most often treated with a combination of surgery and chemotherapy and/or radiation therapy (in about 55% of cases). In some instances, non-curative surgery may make other treatments more effective. Debulking a cancer—making it smaller by surgical removal of a large part of it—is thought to make radiation and chemotherapy more effective.

Surgery is often used to accurately assess the nature and extent of a **cancer**. Most cancers cannot be adequately identified without examining a sample of the abnormal tissue under a microscope. Such tissue samples are procured during a surgical procedure. Surgery may also be used to determine exactly how far a tumor has spread.

There are a few standard methods of comparing one cancer to another for the purposes of determining

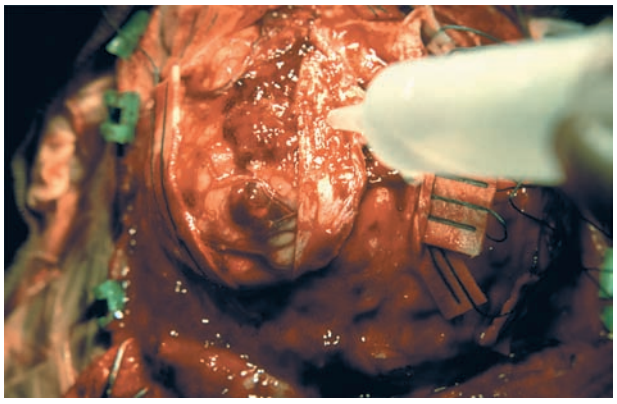


A comparison of benign (top of illustration) and malignant tumor characteristics. *(Illustration by Hans & Cassady, Inc. Reproduced by permission of Gale, a part of Cengage Learning.)*

appropriate treatments and estimating outcomes. These methods are referred to as staging. The most commonly used method is the TNM system, including:

- "T" stands for tumor, and reflects the size of the tumor.
- "N" represents the spread of the cancer to lymph nodes, largely determined by those nodes removed at surgery that contain cancer cells. Since cancers spread mostly through the lymphatic system, this is a useful measure of a cancer's ability to disperse.
- "M" refers to metastasis, and indicates if metastases are present and how far they are from the original cancer.

Staging is particularly important with such lymphomas as Hodgkin's disease, which may appear in many places in the lymphatic system. Surgery is a useful tool for staging such cancers and can increase the chance of a successful cure, since radiation treatment is often curative if all the cancerous sites are located and irradiated.



A tumor inside the brain is being removed. *(Custom Medical Stock Photo, Inc. Reproduced by permission.)*

KEY TERMS

Aspiration—A technique for obtaining a piece of tissue for biopsy by using suction applied through a needle attached to a syringe.

Biopsy—The removal of living tissue from the body, done in order to establish a diagnosis.

Debulking—Surgical removal of a major portion of a tumor so that there is less of the cancer left for later treatment by chemotherapy or radiation.

Mammogram—A set of x rays taken of the front and side of the breast; used to diagnose various abnormalities of the breast.

Metastasis (plural, metastases)—A growth of cancer cells at a site in the body distant from the primary tumor.

Oncologist—A physician who specializes in the diagnosis and treatment of tumors.

Palliative—Offering relief of symptoms, but not a cure.

Pap test—The common term for the Papanicolaou test, a simple smear method of examining stained cells to detect cancer of the cervix.

Staging—The classification of cancerous tumors according to the extent of the tumor.

Demographics

The American Cancer Society estimates that approximately 1.45 million cases of cancer are diagnosed in the United States each year. Seventy-eight percent of cancers are diagnosed in men and women over the age of 55, although cancer may affect individuals of any age. Men develop cancer more often than women; one in two men will be diagnosed with cancer during his lifetime, compared to one in three women. Cancer affects individuals of all races and ethnicities, although incidence may differ among these groups by cancer type.

Description

Surgery may be used to remove tumors for diagnostic or therapeutic purposes.

Diagnostic tumor removal

A biopsy is a medical procedure that obtains a small piece of tissue for diagnostic testing. The sample is examined under a microscope by a doctor who specializes in the effects of disease on body tissues (a pathologist) to detect any abnormalities. A definitive diagnosis of cancer cannot be made unless a sample of the abnormal tissue is examined histologically (under a microscope).

There are four main biopsy techniques used to diagnose cancer, including:

- Aspiration biopsy. A needle is inserted into the tumor and a sample is withdrawn. This procedure may be performed under local anesthesia or with no anesthesia at all.
- Needle biopsy. A special cutting needle is inserted into the core of the tumor and a core sample is cut out. Local anesthesia is most often administered.
- Incisional biopsy. A portion of a large tumor is removed, usually under local anesthesia in an outpatient setting.
- Excisional biopsy. An entire cancerous lesion is removed along with surrounding normal tissue (called a clear margin). Local or general anesthesia may be used.

Therapeutic tumor removal

Once surgical removal has been decided, a surgical oncologist will remove the entire tumor, taking with it a large section of the surrounding normal tissue. The healthy tissue is removed to minimize the risk that abnormal tissue is left behind. Tumors may be removed by cutting with steel instruments, by the use of a laser beam, by radiofrequency ablation (the use of radiofrequency energy to destroy tissue), by cryoablation (the use of extreme cold to freeze and thus destroy the tumor), or by injecting alcohol into the tumor.

When surgical removal of a tumor is unacceptable as a sole treatment, a portion of the tumor is removed

MOSES JUDAH FOLKMAN (1933–2008)

(AP Images.)

Moses Judah Folkman was born in Cleveland, Ohio, on February 24, 1933. He was one of three children born to Bessie and Jerome Folkman. Because Folkman's father, a rabbi, would take his children with him when he visited sick individuals in the hospital, his son Judah dreamed of becoming a surgeon. Young Folkman requested a microscope for his bar mitzvah present and upon receiving it, set up a laboratory in his parents basement.

Folkman entered Ohio State University as a pre-med student, graduating in 1953 after only three years of study. He then went on to Harvard Medical School, where he helped create one of the first pacemakers ever produced and he received his medical degree in 1957. Folkman completed his internship and residency at Massachusetts General Hospital in Boston. In 1960, he married Paula Prial and the couple moved to Bethesda, Maryland where Folkman worked as a lieutenant in the U.S. Navy at the National Naval Medical Center. It was here, with the help of his colleague, Fredrich Becker, that Folkman would make his initial discovery dealing with angiogenesis. Folkman found that a tumor would only grow if it had blood supplied to it. Additionally, the tumor would promote the growth of new blood vessels.

Folkman also held positions as a professor and surgeon for many years, including professor of Cell Biology at Harvard Medical School, but in 1981, he retired and became director of the Children's Hospital Surgical Research Laboratories in Boston. He died in 2008. Folkman's research opened new doorways that may allow scientists to ultimately find a cure for cancer.

to debulk the mass; this process is called cytoreduction. Cytoreductive surgery aids radiation and chemotherapy treatments by increasing the sensitivity of the tumor and decreasing the number of necessary treatment cycles.

Certain types of skin tumors can be removed by a technique called Mohs micrographic surgery, developed in the late 1930s by Dr. Frederick E. Mohs. The Mohs method involves four steps: surgical removal of the tumor; making a slide of the removed tissue and examining it for cancer cells (called mapping the tissue); interpreting the microscope slides and removing more tissue if necessary until no more cancer cells are found; and performing **reconstructive surgery** to cover the wound.

A newer technique for removing some tumors of the spinal cord involves the use of a suction tip rather than a scalpel. The newer technique appears to have a wider margin of safety when working around the delicate structures of the central nervous system.

In some instances, the purpose of tumor removal is not to cure the cancer, but to relieve the symptoms of a patient who cannot be cured. This approach is called palliative surgery. For example, a patient with advanced cancer may have a tumor causing significant **pain** or bleeding; in such a case, the tumor may be removed to ease the patient's pain or other symptoms even though a cure is not possible.

Seeding

The surgical removal of malignant tumors demands special considerations. There is a danger of spreading cancerous cells during the process of removing abnormal tissue (called seeding). Presuming that cancer cells can implant elsewhere in the body, the surgeon must minimize the dissemination of cells throughout the operating field or into the bloodstream.

Special techniques called block resection and no-touch are used. Block resection involves taking the entire specimen out as a single piece. The no-touch technique involves removing a specimen by handling only the normal tissue surrounding it; the cancer itself is never touched. These approaches prevent the spread of cancer cells into the general circulation. The surgeon takes great care to clamp off the blood supply first, preventing cells from leaving by that route later in the surgery.

Diagnosis/Preparation

A tumor may first be palpated (felt) by the patient or by a healthcare professional during a **physical examination**. A tumor may be visible on the skin or protrude outward from the body. Still other tumors are not evident until their presence begins to cause such symptoms as weight loss, **fatigue**, or pain. In some instances, tumors are located during routine tests (e.g., a yearly mammogram or Pap smear).

Aftercare

Retesting and periodical examinations are necessary to ensure that a tumor has not returned or metastasized after total removal.

Risks

Each tumor removal surgery carries certain risks that are inherent to the procedure. There is always a risk of misdiagnosing a cancer if an inadequate sample was procured during biopsy, or if the tumor was not properly located. There is a chance of infection of the surgical site, excessive bleeding, or injury to adjacent tissues. The possibility of metastasis and seeding are risks that have to be considered in consultation with an oncologist.

Normal results

The results of a tumor removal procedure depend on the type of tumor and the purpose of the treatment. Most benign tumors can be removed successfully with no risk of the abnormal cells spreading to other parts of the body and little risk of the tumor returning. Malignant tumors are considered successfully removed if the entire tumor can be removed, if a clear margin of healthy tissue is removed with the tumor, and if there is no evidence of metastasis. The normal results of palliative tumor removal are a reduction in the patient's symptoms with no impact on length of survival.

Morbidity and mortality rates

The recurrence rates of benign and malignant tumors after removal depend on the type of tumor and its location. The rate of complications associated with tumor removal surgery differs by procedure, but is generally very low.

Alternatives

If a benign tumor shows no indication of harming nearby tissues and is not causing the patient any symptoms, surgery may not be required to remove it. Chemotherapy, radiation therapy, and biological therapy are treatments that may be used alone or in conjunction with surgery.

Turner syndrome

Definition

Turner syndrome is a chromosomal disorder affecting females wherein one of the two X-chromosomes is defective or completely absent.

Demographics

The prevalence of Turner syndrome is widely reported as being approximately one per 2,000 live female births, with little difference among racial or ethnic groups. About 15% of spontaneous abortions of female fetuses have this genetic abnormality. The incidence of Turner syndrome seems to be slightly higher in fetuses conceived by older women.

Description

Chromosomes are structures in the nucleus of every cell in the human body. Chromosomes contain the genetic information necessary to direct the growth and normal functioning of all cells and systems of the body. A normal individual has a total of 46 chromosomes in each cell, two of which are responsible for determining gender. Normally, females have two X-chromosomes (one from each parent) and males have one X and one Y-chromosome.

A low hairline at the back of the neck is one of several characteristics of Turner syndrome. *(Custom Medical Stock Photo, Inc. Reproduced by permission.)*

In Turner syndrome, an error occurring very early in development results in an abnormal number and arrangement of chromosomes. Most commonly, an individual with Turner syndrome will be born with 45 chromosomes in each cell rather than 46. The missing chromosome is an X-chromosome. The affected person is always female.

About 1–2% of all female conceptions have a missing X-chromosome. Of these, the majority (99%) spontaneously abort, usually during the first trimester of **pregnancy**. With ultrasound being used more frequently, researchers have realized that some pregnancies with a missing X-chromosome that progress into the second trimester are associated with nuchal cysts, severe **lymphedema**, or hydrops fetalis. These pregnancies are associated with a high frequency of fetal **death**.

Causes and symptoms

Turner syndrome is a disorder associated with characteristic defects in the X-chromosome. The most common presentation is a female with a single X-chromosome and an absent X-chromosome. A Greek study from 1999 reported that the intact X-chromosome was as likely to come from the mother as from the father. This means that there is no parental pattern of responsibility for the missing or defective X-chromosome.

Another less common genetic pattern for Turner Syndrome (35%) is a mosaic. A Danish study reported that mosaicism has an effect on malformations that are associated with Turner syndrome. Researchers have found that XX/XO mosaic individual have a different growth pattern from children who are completely XO.

The exact location of the genes on the X-chromosome involved in Turner syndrome has not been determined as of 2010. Evidence exists that there is a locus for stature on the distal portion of the short arm of the X chromosome; there are loci for normal ovarian function on both the short and long arms; and there are loci contributing to fetal viability on the long arm of X.

Turner syndrome is characterized by retarded growth that leads to a small stature and frequent **infertility**. Individuals with Turner syndrome report an increased incidence of **fractures** in childhood and osteoporotic fractures in adulthood. The incidence of **diabetes mellitus** (both insulin dependent [type 1] and non-insulin dependent [type 2] varieties) has been reported increased in Turner syndrome. Ischemic heart disease, **stroke**, and **hypertension** are also more common.

Growth in children with Turner syndrome is characterized by a slight **intrauterine growth retardation**, relatively normal growth rates for the first several years

KEY TERMS

Aortic dissection—A tear in the aorta (the main blood vessel carrying blood away from the heart) that allows blood to flow between layers of the aorta, eventually causing it to fail.

Chromosome—A microscopic thread-like structure found within each cell of the body that consists of a complex of proteins and DNA. Humans have 46 chromosomes arranged into 23 pairs. Changes in either the total number of chromosomes or their shape and size (structure) may lead to physical or mental abnormalities.

Diabetes mellitus—A disease in which insufficient insulin is made by the body to metabolize sugars.

Hydrops fetalis—Extreme edema of the fetus.

Mosaic—A term referring to a genetic situation in which an individual's cells do not have the exact same composition of chromosomes. In mosaic Turner syndrome, some cells are normal and have two X chromosomes (XX), while others are abnormal and have only one X chromosome (XO).

Nuchal cysts—Small cysts in the fetus's neck that present in 1% of pregnancies.

of life, a progressive deceleration of growth later in childhood, and the lack of a pubertal growth spurt.

Most individuals with Turner syndrome are not mentally retarded. They may have some learning disabilities, particularly with regard to spatial perception, visual-motor coordination, and mathematics. As a result, the nonverbal IQ in Turner syndrome tends to be lower than the verbal IQ.

Cardiovascular malformations are well-recognized congenital anomalies in Turner syndrome. Dilation and dissection of the aorta are reported in approximately half of women with Turner syndrome. heart valve abnormalities also are common. Because of the potential consequences of aortic dilation, some experts recommend screening all individuals with Turner syndrome.

Normal pubertal development and spontaneous menstrual periods do not occur in the majority of children with Turner syndrome. It is estimated that 3–8% of girls with a single X-chromosome and 12–21% of females with sex chromosome mosaicism may have normal pubertal development and spontaneous menstrual periods. A few pregnancies have been reported in women with Turner syndrome.

Diagnosis

Turner syndrome is diagnosed on the basis of genetic analysis of chromosomes. This can be done prior to birth or after birth.

Treatment

Traditional

Because it is so dangerous, experts suggest screening for **aortic dissection**, although the specific timing for this screening is controversial. **Plastic surgery** to correct webbing of the neck should be considered at an early age (before entering school) for girls with Turner syndrome.

Drugs

Most individuals with Turner syndrome require female hormone therapy to promote development of secondary sexual characteristics and menstruation. The time of beginning therapy varies with individuals. Experts recommend that therapy begin when a woman expresses concern about her onset of **puberty**.

All women receiving long-term, exogenous female hormone therapy require periodic gynecological examinations, because those with Turner syndrome have an increased risk of developing neoplasms such as gonadoblastoma and dysgerminoma, which arise from their rudimentary streak gonads.

Prognosis

Most women with Turner syndrome can live relatively normal lives. The prognosis for a person with Turner syndrome is dependent on other conditions that may be present. Care must be taken to regularly monitor the health problems that are associated with Turner syndrome. For example, heart or kidney defects, **hearing loss**, or the development of inflammatory bowel disease may significantly affect the quality of life. Without these types of conditions, however, their life expectancy is close to normal. Support will be necessary to help an adolescent girl cope with body image issues and to help some women accept the fact that they will never be able to have children.

Prevention

Turner syndrome is a genetic disorder that cannot be prevented. Prenatal testing may give parents information about whether their child has Turner syndrome and prepare them to make decisions about the child's future.

2,3-diphosphoglycerate test

Definition

2,3-diphosphoglycerate (2,3-DPG) is a substance made in the red blood cells. It controls the movement of oxygen from red blood cells to body tissues. 2,3-DPG testing is done to help investigate both a deficiency in red blood cells (anemia) and an unexplained increase of red blood cells, called erythrocytosis.

Purpose

Hemoglobin, the protein in the blood that carries oxygen, uses 2,3-DPG to control how much oxygen is released once the blood gets out into the tissues. The more 2,3-DPG in the cell, the more oxygen is delivered to body tissues. Conversely, the less 2,3-DPG in the cell, the less oxygen is delivered.

Increasing the amount of 2,3-DPG is the body's primary way of responding to a lack of oxygen. Anemia, obstructive lung disease, **cystic fibrosis**, and **congenital heart disease** are all accompanied by increases in 2,3-DPG. When more oxygen is required because of increased metabolism, such as in **hyperthyroidism**, more 2,3-DPG is produced.

Decreased 2,3-DPG results from an inherited lack of the red blood cell enzymes 2,3-DPG mutase and 2,3-DPG phosphatase. These enzymes are needed to make 2,3-DPG. Without 2,3-DPG to control the movement of oxygen to its tissues, the body responds by making more red blood cells, a condition called erythrocytosis. The outside membrane of the cell is weakened, causing it to have an irregular shape and burst, or hemolyze, easily. This condition is called nonspherocytic **hemolytic anemia**.

2,3-DPG levels are important in large blood transfusions, because stored blood quickly loses 2,3-DPG and its ability to deliver oxygen. After **transfusion**, the red cells rebuild the 2,3-DPG, but it takes about 24 hours to regain a normal level of 2,3-DPG and hemoglobin function.

Description

In the laboratory, a person's serum is mixed with a substance that will react with 2,3-DPG. The end product of this reaction is measured; and from that measurement, the amount of 2,3-DPG in the person's serum is determined. Results are usually available the next day.

Preparation

This test requires drawing 5-10 mL of blood. The patient should not **exercise** before having the blood drawn. Exercise increases the body's need for oxygen and could cause a temporary increase in levels of 2,3-DPG.

KEY TERMS

Anemia—A reduction in the number of erythrocytes or red blood cells. Erythrocytes are necessary to form hemoglobin for transporting oxygen.

Erythrocytosis—Increased production of red blood cells.

Hemoglobin—A protein within the red blood cell that carries oxygen.

Nonspherocytic hemolytic anemia—Anemia caused by variably shaped red blood cells that burst, or hemolyze, easily.

Aftercare

Discomfort or bruising may occur at the puncture site, or the person may feel dizzy or faint. Pressure to the puncture site until the bleeding stops will reduce bruising. Warm packs to the puncture site will relieve discomfort.

Normal results

Normal results will vary based on the laboratory and testing methods used.

Abnormal results

Decreased levels of 2,3-DPG are found in cases of erythrocytosis and nonspherocytic hemolytic anemia caused by 2,3-DPG mutase and 2,3-DPG phosphatase deficiencies. Lower levels are also commonly found after large blood transfusions.

Increased levels of 2,3-DPG are found in conditions in which the body needs more oxygen, such as anemia, obstructive lung disease, cystic fibrosis, congenital heart disease, and hyperthyroidism. High altitudes and participating in exercise sessions before the test can also give false high values.

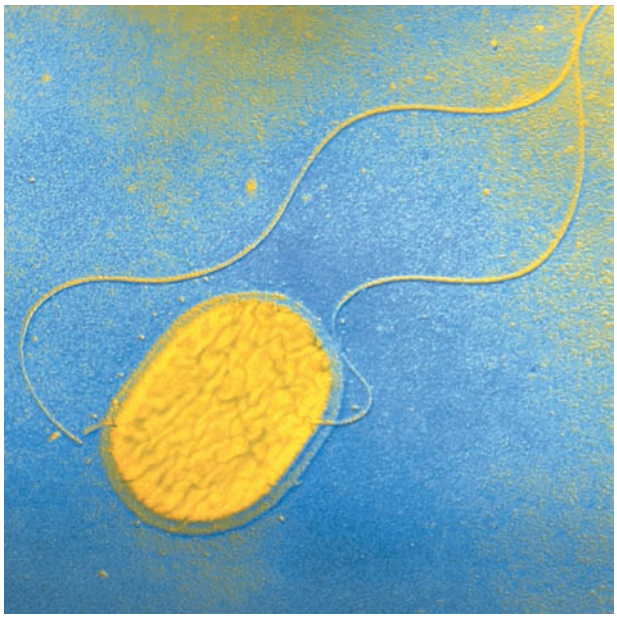
Typhoid fever

Definition

Typhoid **fever** is a severe infection caused by a bacterium, *Salmonella typhi*. *S. typhi* is in the same family of bacteria as the type spread by chicken and eggs, commonly known as salmonella **poisoning** or **food poisoning**. Unlike the bacteria that cause food poisoning, *S. typhi* bacteria do not have **vomiting** and **diarrhea** as the most prominent symptoms of their presence in humans. Instead, persistently high fever is the hallmark of *S. typhi* infection.

Demographics

Typhoid fever is rare in industrialized countries with good sewage treatment and clean water supplies. In the United States in 2006, there were 314 reported cases. Of these, about 80% occurred in individuals who had traveled outside the United States to areas where typhoid fever is common. Those areas include Asia, Africa, Latin America, the Caribbean, and



Transmission electron microscopy (TEM) scan of *Salmonella typhi*, the bacteria that causes typhoid fever in humans. *(Custom Medical Stock Photo, Inc. Reproduced by permission.)*

MARY MALLON (1869–1938)

(© Bettman/Corbis.)

Mary Mallon was born in Cookstown, Ireland, on September 23, 1869, to Catherine Igo and John Mallon. As a teenager, Mallon left her parents and immigrated to New York to live with an aunt and uncle. Until 1906, when George A. Soper began to study an outbreak of typhoid fever in Long Island, little was known about Mallon.

Soper was called to identify possible causes of an eruption of typhoid fever at a summer house in Oyster Bay. After examining the food and water in a futile attempt to discover contaminants, Soper decided that the disease was probably transmitted by a human carrier. He soon learned that the cook had disappeared and tracked Mallon to her new place of employment, expecting her cooperation in dealing with the matter. Soper eventually turned the case over to the New York City Department of Health. When Mallon was ultimately caught, she refused treatment and was held for three years as a threat to the public. In 1910, a judge granted her release with the stipulation that she not seek employment as a cook, since the disease was transmitted through food. Mallon agreed but, in 1915, an outbreak of typhoid at a hospital was, once again, linked to her. When Soper investigated this incident he learned that employees had nicknamed one of the cooks "Typhoid Mary."

After Mallon was found, she was taken into custody, and spent the rest of her life at Riverside Hospital. Mallon died on November 11, 1938.

Oceania. Although typhoid fever can be found in all those areas, 80% of cases worldwide are found in Bangladesh, China, India, Indonesia, Laos, Nepal, Pakistan, and Vietnam. As of 2009, about 21.4 million people developed typhoid fever each year and 200,000 people died of the disease annually.

Description

Typhoid fever is passed from person to person through poor hygiene, such as incomplete or no hand washing after using the toilet. This allows *S. typhi* to enter the food and water supply. The bacteria are ingested and then passed into the stool and urine of infected patients. They may continue to be present in the stool of asymptomatic carriers—persons who have recovered from the symptoms of the disease but continue to carry the bacteria. This carrier state occurs in about 3% of all individuals who have recovered from typhoid fever. Persons who are carriers of the disease and who handle food can be the source of epidemic spread of typhoid. One such individual gave her name to the expression "Typhoid Mary," a name given to someone whom others avoid.

Causes and symptoms

S. typhi must be ingested to cause disease. Transmission often occurs when a person in the carrier state does not wash hands thoroughly (or not at all) after defecation and serves food to others. This pathway is sometimes called the fecal-oral route of disease transmission. In countries where open sewage is accessible to flies, the insects land on the sewage, pick up the bacteria, and then contaminate food to be eaten by humans. In countries with poor sewage treatment facilities, sewage can contaminate the water supply and typhoid fever can spread by drinking contaminated water.

After being swallowed, the *S. typhi* bacteria enter the digestive tract where they are taken in by cells called mononuclear phagocytes. These phagocytes are cells of the immune system, whose job it is to engulf and kill invading bacteria and viruses. In the case of *S. typhi*, however, the bacteria are able to survive ingestion by the phagocytes, and multiply within these cells. This period of time, during which the bacteria are multiplying within the phagocytes, is the 10- to 14-day incubation period of typhoid fever. When huge numbers of bacteria fill an individual phagocyte, they spill out of the cell and into the bloodstream, where their presence begins to cause symptoms.

The presence of increasingly large numbers of bacteria in the bloodstream (**bacteremia**) is responsible for an increasingly high fever, which lasts throughout the four to eight weeks of the disease in untreated

KEY TERMS

Asymptomatic—A state in which a person experiences no symptoms of a disease.

Bacteremia—Bacteria in the blood.

Carrier—A person who has a particular disease agent present within his or her body, and can pass this agent on to others, but who displays no symptoms of infection.

Epidemic—A large number of cases of the same disease or infection all occurring within a short time period in a specific location.

Incubation period—The time between when an individual becomes infected with a disease-causing agent and when symptoms begin to appear.

Mononuclear phagocyte—A type of cell of the human immune system that ingests bacteria, viruses, and other foreign matter, thus removing potentially harmful substances from the bloodstream. These substances are usually then digested within the phagocyte.

Rose spots—A pinkish rash across the trunk or abdomen that is a classic sign of typhoid fever.

Sickle cell disease—An inherited disorder characterized by a genetic flaw in hemoglobin production. (Hemoglobin is the substance within red blood cells that enables them to transport oxygen.) The hemoglobin that is produced has a kink in its structure that forces the red blood cells to take on a sickle shape, inhibiting their circulation and causing pain. This disorder primarily affects people of African descent.

individuals. Other symptoms of typhoid fever include **constipation** (at first), **nausea**, extreme **fatigue**, **headache**, joint **pain**, and a rash across the abdomen known as rose spots.

The bacteria move from the bloodstream into certain tissues of the body, including the gallbladder and lymph tissue of the intestine (called Peyer's patches). The tissue's response to this invasion causes symptoms ranging from inflammation of the gallbladder (**cholecystitis**) to intestinal bleeding to actual perforation of the intestine. Perforation of the intestine refers to an actual hole occurring in the wall of the intestine, with leakage of intestinal contents into the abdominal cavity. This leakage causes severe irritation and inflammation of the lining of the abdominal cavity, which is called **peritonitis**. Peritonitis is a frequent cause of **death** from typhoid fever.

Other complications of typhoid fever include liver and spleen enlargement, sometimes so great that the spleen ruptures or bursts; anemia, or low red blood cell count due to blood loss from the intestinal bleeding; joint infections, which are especially common in patients with **sickle cell disease** and immune system disorders; **pneumonia** caused by a bacterial infection (usually *Streptococcus pneumoniae*), which is able to take hold due to the patient's weakened state; heart infections; and **meningitis** and infections of the brain, which cause mental confusion and even **coma**. It may take a patient several months to recover fully from untreated typhoid fever.

Diagnosis

In some cases, the doctor may suspect the diagnosis if the patient has already developed the characteristic rose spots, or if he or she has a history of recent travel in areas with poor sanitation. The diagnosis is confirmed by a **blood culture**. Samples of a patient's stool, urine, and bone marrow can also be used to grow *S. typhi* in a laboratory for identification under a microscope. Cultures are the most accurate method of diagnosis. Blood cultures usually become positive in the first week of illness in 80% of patients who have not taken **antibiotics**.

Treatment

Drugs

Antibiotics are the treatment of choice for typhoid fever. As of the late 2000s, commonly used drugs are ceftriaxone and cefoperazone. Ciprofloxacin is sometimes given as follow-up therapy. It should be noted, that antibiotic resistance is common in *S. typhi*. Forty-three percent of samples of *S. typhi* collected from patients in the United States were resistant to at least one antibiotic. The choice of antibiotic(s) used to treat typhoid fever is determined by the origin of the disease, sensitivity of cultures of the bacterium to specific antibiotics, and response to treatment.

Carriers of *S. typhi* must be treated even when they do not show any symptoms of the infection, because carriers are responsible for the majority of new cases of typhoid fever. Eliminating the carrier state is a fairly difficult task. It requires treatment with one or even two different medications over a period of four to six weeks. The antibiotics most commonly given are ampicillin (sometimes given together with probenecid) and amoxicillin. In the case of a carrier with **gallstones**, surgery

may need to be performed to remove the gallbladder. This measure is necessary because typhoid bacteria are often housed in the gallbladder, where they may survive in spite of antibiotic treatment. In some patients, treatment with rifampin and trimethoprim-sulfamethoxazole is sufficient to eradicate the bacteria from the gallbladder without surgery.

Prognosis

The prognosis for recovery is good for most patients. In the era before effective antibiotics were discovered, about 12% of all typhoid fever patients died of the infection. Now, fewer than 1% of patients who receive prompt antibiotic treatment will die. The mortality rate is highest in the very young and very old, and in patients with **malnutrition**. The most ominous signs are changes in a patient's state of consciousness, including stupor or coma.

Prevention

Hygienic sewage disposal systems in a community, good water treatment facilities, and proper personal hygiene are the most important factors in preventing typhoid fever. Immunizations are available for travelers who expect to visit countries where *S. typhi* is a known public health problem. Some of these immunizations provide only short-term protection (for a few months), while others may be effective for several years. Efforts are being made to develop vaccines that provide a longer period of protection with fewer side effects from the vaccine itself. The most commonly reported side effects are flu-like **muscle cramps** and abdominal pain.

Typhus

Definition

Several different illnesses are called "typhus," all of them caused by one of the bacteria in the family Rickettsiae. Each illness occurs when the bacteria is passed to a human through contact with an infected insect.

Description

The four main types of typhus are:

- epidemic typhus
- Brill-Zinsser disease
- endemic or murine typhus
- scrub typhus

These diseases are all somewhat similar, although they vary in terms of severity. The specific type of *Rickettsia* that causes the disease also varies, as does the specific insect that can pass the bacteria along.

Epidemic typhus, which is sometimes called jail **fever** or louse-borne typhus, is caused by *Rickettsia prowazekii*, which is carried by body lice. When the lice feed on a human, they may simultaneously defecate. When the person scratches the bite, the feces (which carrys the bacteria) are scratched into the wound. Body lice are common in areas in which people live in overcrowded, dirty conditions, with few opportunities to wash themselves or their clothing. Because of this fact, this form of typhus occurs simultaneously in large numbers of individuals living within the same community; that is, in epidemics. This type of typhus

occurs when cold weather, poverty, war, and other disasters result in close living conditions that encourage the maintenance of a population of lice living among humans. Some medical historians think that the Great **Plague** of Athens in 430 B.C. may have been epidemic typhus. Epidemic typhus is now found in the mountainous regions of Africa, South America, and Asia.

Brill-Zinsser disease is a reactivation of an earlier infection with epidemic typhus. It affects people years after they have completely recovered from epidemic typhus. When something causes a weakening of their immune system (like **aging**, surgery, illness), the bacteria can gain hold again, causing illness. This illness tends to be extremely mild.

Endemic typhus is carried by fleas. When a flea lands on a human, it may defecate as it feeds. When the person scratches the itchy spot where the flea was feeding, the bacteria-laden feces are scratched into the skin, thus causing infection. The causative bacteria is called *Rickettsia typhi*. Endemic typhus occurs most commonly in warm, coastal regions. In the United States, southern Texas and southern California have the largest number of cases.

Scrub typhus is caused by *Rickettsia tsutsugamushi*. This bacteria is carried by mites or chiggers. As the mites feed on humans, they deposit the bacteria. Scrub typhus occurs commonly in the southwest Pacific, southeast Asia, and Japan. It is a very common cause of illness in people living in or visiting these areas. It occurs more commonly during the wet season.

KEY TERMS

Antibody—Specialized cells of the immune system, which can recognize organisms that invade the body (such as bacteria, viruses, and fungi). The antibodies are then able to set off a complex chain of events designed to kill these foreign invaders.

Bioterrorism—The use of disease microorganisms to intimidate or terrorize a civilian population.

Endemic—Occurring naturally and consistently in a particular area.

Epidemic—A large cluster of cases all occurring at about the same time within a specific community or region.

Causes and symptoms

The four types of typhus cause similar types of illnesses, though varying in severity.

Epidemic typhus causes fever, **headache**, weakness, and muscle aches. It also causes a rash composed of both spots and bumps. The rash starts on the back, chest, and abdomen, then spreads to the arms and legs. The worst types of complications involve swelling in the heart muscle or brain (**encephalitis**). Without treatment, this type of typhus can be fatal.

Brill-Zinsser disease is quite mild, resulting in about a week-long fever, and a light rash similar to that of the original illness.

Endemic typhus causes about 12 days of high fever, with chills and headache. A light rash may occur.

Scrub typhus causes a wide variety of effects. The main symptoms include fever, headache, muscle aches and pains, **cough**, abdominal **pain**, **nausea and vomiting**, and **diarrhea**. Some patients experience only these symptoms. Some patients develop a rash, which can be flat or bumpy. The individual spots eventually develop crusty black scabs. Other patients go on to develop a more serious disease, in which encephalitis, **pneumonia**, and swelling of the liver and spleen (hepatosplenomegaly) occur.

Diagnosis

A number of tests exist that can determine the reactions of a patient's antibodies (immune cells in the blood) to the presence of certain viral and bacterial markers. When the antibodies react in a particular way, it suggests the presence of a rickettsial infection. Many tests require a fair amount of time for processing, so practitioners will frequently begin treatment without completing tests, simply on the basis of a patient's symptoms.

Treatment

The **antibiotics** tetracycline or chloramphenicol are used for treatment of each of the forms of typhus.

Prognosis

The prognosis depends on what types of complications an individual patient experiences. While children usually recover well from epidemic typhus, older adults may have as much as a 60% **death** rate without treatment. Brill-Zinsser, on the other hand, carries no threat of death. People usually recover uneventfully from endemic typhus, although the elderly, those with other medical problems, or people mistakenly treated with sulfa drugs may have a 1% death rate from the illness. Scrub typhus responds well to appropriate

treatment, but untreated patients have a death rate of about 7%.

The relatively high death rate from untreated typhus is one reason why some researchers are concerned that its causative organisms might be used in the future as agents of bioterrorism.

Prevention

Prevention for each of these forms of typhus includes avoidance of the insects that carry the causative bacteria. Other preventive measures include good hygiene and the use of insect repellents.

Tzanck preparation

Definition

Tzanck preparation is a rapid test done to diagnose infections caused by herpesviruses. Cells are examined under a microscope for signs of infection.

Purpose

Herpesviruses are responsible for several superficial infections. Varicella zoster virus causes **chickenpox** and **shingles**, herpes simplex type 1 causes the **common cold** sore or **fever** blister, and herpes simplex type 2 causes the sexually transmitted disease **genital herpes**. They are all characterized by blisters and ulcers.

KEY TERMS

Herpes—A family of viruses including herpes simplex types 1 and 2, and herpes zoster (also called varicella zoster). Herpes viruses cause several infections, all characterized by blisters and ulcers, including chickenpox, shingles, genital herpes, and cold sores or fever blisters.

Physicians usually can diagnose herpes infections simply by looking at the type of blisters and ulcers, and their distribution on the person's body. Sometimes laboratory evidence of herpes is needed to confirm the diagnosis. For example, herpes can be devastating to a newborn baby or a person with a weakened immune system. Treatment can begin once herpes is confirmed in a laboring mother's genital ulcers or in the skin blisters of an immunocompromised person. A lab tries to grow (culture) the virus that may be present in the blister. This lab test takes several days to complete, but the Tzanck preparation takes minutes.

Description

The Tzanck preparation is done by smearing cells taken from a fresh blister or ulcer onto a microscope slide. The cells are stained with a special stain, such as Wright's stain, and then examined under a microscope for characteristic changes caused by a herpesvirus. Herpes causes giant cells with multiple nuclei. The shape of each nucleus appears molded to fit together with those adjacent. The background of the cell looks like ground glass and contains small dark spots called inclusion bodies.

Tzanck preparation is also called a Tzanck smear, herpes stain for inclusion bodies, or inclusion bodies stain. Results are available the same or following day, often within minutes.

Preparation

A fresh blister is opened with a scalpel or sterile needle. The physician scrapes the base of the blister with the scalpel, gathers as much cellular material as possible, and gently spreads it on a microscope slide.

Normal results

A normal smear shows no evidence of a herpes infection. This test may also have false negatives. Studies have shown that the Tzanck preparation shows signs of

infection in only 50–79% of people with a herpes infection. A negative Tzanck preparation may have to be confirmed by a herpes culture.

Abnormal results

A smear that shows evidence of herpes infection does not distinguish between the various infections caused by herpes virus. The physician uses the person's symptoms and other clinical findings to distinguish between these infections. In certain cases, the physician will follow a positive Tzanck smear with a culture for confirmation.

U

Ulcer surgery

Definition

Ulcer surgery is a procedure used to cure peptic ulcer disease when medications have failed.

Purpose

Ulcer surgery is used to relieve a present peptic ulcer disease and to prevent recurrence of it.

Surgery is usually required if the ulcer is in one of the following states:

- perforated and overflowed into the abdomen
- scarred or swelled so much that the bowel is obstructed
- acute bleeding
- defied all other types of treatment

The need for ulcer surgery has diminished greatly over the past 20–30 years due to the discovery of two new classes of drugs and the presence of the causal germ *Helicobacter pylori* in the stomach. The drugs are the H2 blockers, such as cimetidine and ranitidine, and the **proton pump inhibitors**, such as omeprazole. These effectively arrest acid production. *H. pylori* can be eliminated from most patients with a combination of **antibiotics** and bismuth.

Precautions

There is a tumor of the pancreas that produces a hormone called gastrin. Gastrin causes ulcers by stimulating acid production. If this disease—Zollinger-Ellison syndrome—does not respond to medical treatment, either the tumor or the entire stomach must be removed.

Description

The two primary goals of ulcer surgery, elimination of the current problem and prevention of future problems bring with them a third problem—to perpetuate the normal function of the bowel. The vagus nerves relax the pylorus, allowing the stomach to empty. Cutting the vagus nerves, while reducing the stomach's acid production, also prevents stomach emptying. Therefore, the procedures described must guarantee stomach emptying along with their other goals.

Total gastrectomy

Removing the entire stomach is done only for resistant Zollinger-Ellison syndrome or extensive cancers.

Antrectomy

The lower half of the stomach makes most of the acid and gets all the peptic ulcers above the duodenum. Removing it leaves little place for ulcers to form and little acid to produce them.

Vagotomy

Cutting the vagus nerves can be done in three ways:

KEY TERMS

Gastrin—A type of hormone that produces gastric juice.

Hypoglycemia—An abnormal decrease in blood sugar level.

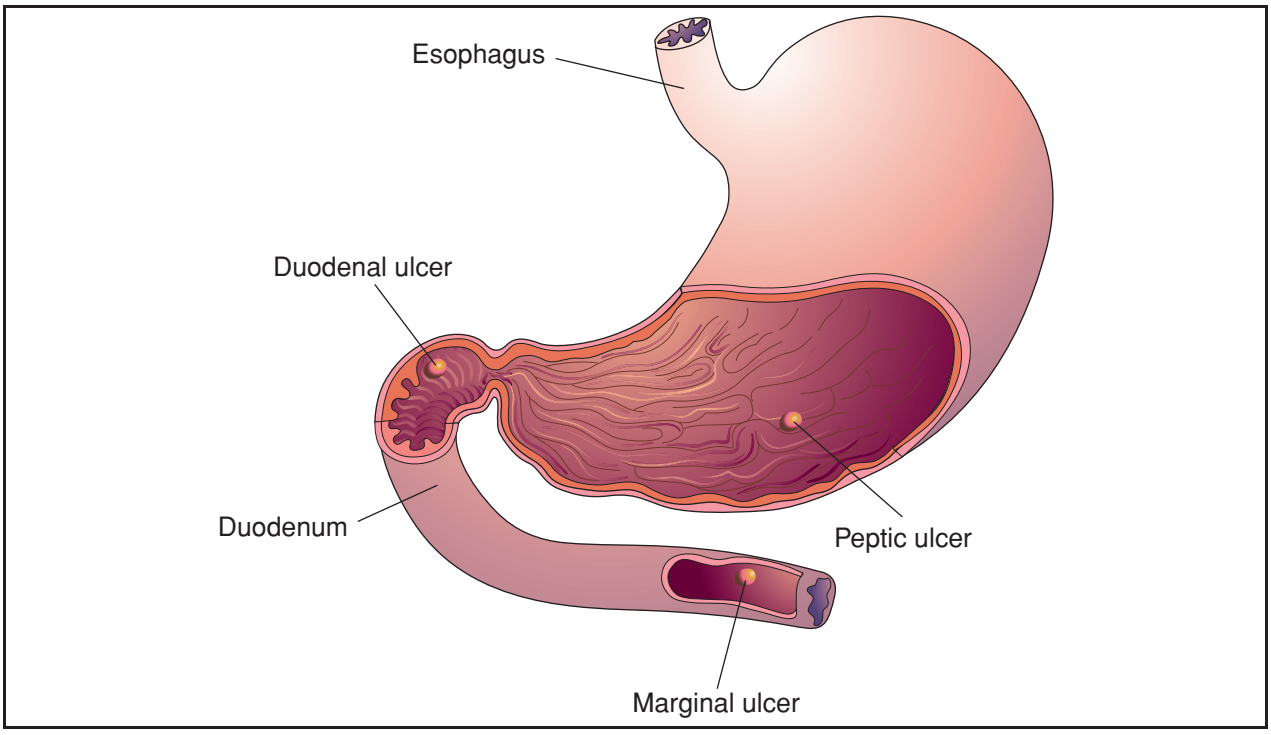
Jejunum—Section of the small intestine.

Laparoscope—A pencil-thin telescope that allows surgery to be done through half-inch incisions.

Pylorus—The opening from the stomach to the intestine.

Vagus nerve—Cranial nerves that supply the internal organs (viscera).

Zollinger-Ellison syndrome—A syndrome marked by peptic ulcers and gastrinomas in the pancreas.



Common sites of ulcers in the human stomach. The need for ulcer surgery has diminished over the past 20-30 years due to the discovery that *Helicobacter pylori*, an infectious bacterium, plays a major role in causing ulcers. *H. pylori* can be eliminated from most patients with a combination of antibiotics and bismuth. *(Illustration by Electronic Illustrators Group. Reproduced by permission of Gale, a part of Cengage Learning.)*

- the main nerves can be cut completely as they enter the abdomen from the chest
- the branches that go to the stomach can be cut as they leave the main nerves
- the tiny branches that stimulate acid production can be cut on the surface of the stomach

Pyloroplasty

Opening up the valve at the outlet of the stomach guarantees that the stomach can empty, even without vagus nerve stimulation. **Pyloroplasty** is ordinarily done by cutting across the muscle that surrounds the outlet. It can also be done by passing a balloon down from the mouth and inflating it forcefully to stretch out the pylorus (opening from the stomach to the intestine).

Close perforation

For some patients all that can be done is to close the hole in the bowel and wait for the patient to recover before initiating corrective surgery.

Billroth I and II

After removing a piece of the stomach, the remainder must be reattached to the rest of the bowel. Simply joining the upper stomach back to the duodenum is called a Billroth I or gastroduodenostomy. It is sometimes better to attach the stomach with another piece of bowel (the jejunum), creating a "y" with the bile drainage and the duodenum forming the second branch of the "y." This part of the procedure is called a gastrojejunostomy. A gastroenterostomy is a more general term for connecting the stomach with any piece of bowel.

A selective **vagotomy** can be done alone. A complete vagotomy requires either a pyloroplasty or antrectomy. An antrectomy must be reconnected with either a Billroth I or a Billroth II.

Some of these procedures are now being done through a laparoscope.

Risks

All of these procedures carry risks, generally in proportion to their benefits. The more extensive surgeries, such as vagotomy and antrectomy with Billroth II reconnection, have the highest success rate and the highest complication rate.

Complications include:

- diarrhea after a meal

- dumping syndrome occurring after a meal and characterized by sweating, abdominal pain, vomiting, lightheadedness, and diarrhea
- hypoglycemia after a meal
- alkaline reflux gastritis marked by abdominal pain, vomiting of bile, diminished appetite, and iron-deficiency anemia
- recurrence of an ulcer
- malabsorption of necessary nutrients, especially iron, in patients who have had all or part of their stomachs removed

Ulcerative colitis *see* **Colitis**

Ulcers (digestive)

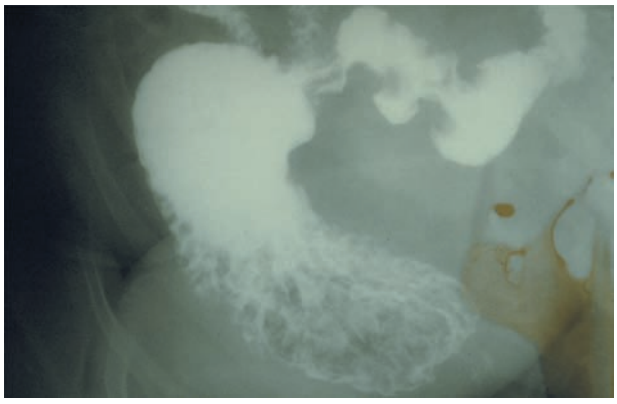
Definition

In general, an ulcer is any eroded area of skin or a mucous membrane marked by tissue disintegration. In common usage, however, ulcer usually is used to refer to disorders in the upper digestive tract.

Demographics

It is estimated that 2% of the adult population in the United States has active peptic ulcers, and that about 10% will develop ulcers at some point in their lives. There are about 500,000 new cases of peptic ulcer in the United States every year, with as many as 4 million recurrences. The male/female ratio for ulcers of the digestive tract is 3:1.

The most common forms of peptic ulcer are duodenal and gastric. About 80% of all ulcers in the digestive tract are duodenal ulcers. This type of ulcer may strike people in any age group but is most common in males between the ages of 20 and 45. The incidence of duodenal ulcers has dropped over the past 30 years. Gastric ulcers account for about 16% of peptic ulcers. They are most common in males between the ages of 55 and 70. The single most common cause of gastric ulcers is the use of **nonsteroidal anti-inflammatory drugs**, or NSAIDs. The widespread use of NSAIDs is thought to explain why the incidence of gastric ulcers in the United States is rising.



A barium x-ray image of a gastric ulcer. *(Custom Medical Stock Photo, Inc. Reproduced by permission.)*

Description

The terms ulcer, gastric ulcer, and peptic ulcer often are used loosely and interchangeably. Peptic ulcers can develop in the lower part of the esophagus, the stomach, the first part of the small intestine (the duodenum), and the second part of the small intestine (the jejunum).

Causes and symptoms

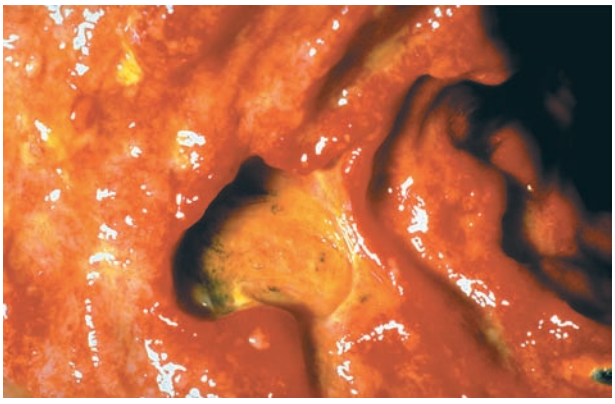
There are three major causes of peptic ulcers: infection, certain types of medication, and disorders that cause oversecretion of stomach juices.

Helicobacter pylori infection

Helicobacter pylori is a rod-shaped gram-negative bacterium that lives in the mucous tissues that line the digestive tract. Infection with *H. pylori* is the most common cause of duodenal ulcers. About 95% of patients with duodenal ulcers are infected with *H. pylori*, as opposed to only 70% of patients with gastric ulcers.

Nonsteroidal anti-inflammatory drugs (NSAIDS)

Nonsteroidal anti-inflammatory drugs, or NSAIDs, are painkillers that many people use for headaches, sore muscles, arthritis, menstrual cramps, and similar complaints. Many NSAIDs are available without prescriptions. Common NSAIDs include **aspirin**, ibuprofen (Advil, Motrin), flurbiprofen (Ansaid, Ocufen), ketoprofen (Orudis), and indomethacin (Indacin). Chronic NSAID users have 40 times the risk of developing a



A clinical photograph of a large duodenal ulcer after surgical removal. The ulcer is the prominent triangular crater at center. *(Photo Researchers, Inc.)*

KEY TERMS

Duodenum—The first of the three segments of the small intestine. The duodenum connects the stomach and the jejunum. Most peptic ulcers are in the duodenum.

Helicobacter pylori—A gram-negative rod-shaped bacterium that lives in the tissues of the stomach and causes inflammation of the stomach lining.

Zollinger-Ellison syndrome—A disorder characterized by the presence of tumors (gastrinomas) that secrete a hormone (gastrin), which stimulates the production of digestive juices.

gastric ulcer as nonusers. Users also are three times more likely than nonusers to develop bleeding or fatal complications of ulcers. Aspirin is the NSAID that is most likely to cause ulcers.

Other syndromes and disorders

Fewer than 5% of peptic ulcers are due to Zollinger-Ellison syndrome, a disorder in which small tumors, called gastrinomas, secrete a hormone (gastrin) that stimulates the production of digestive juices. Because of this excess secretion, these disorders are sometimes called hypersecretory syndromes.

Risk factors

Smoking is an important risk factor that increases a patient's chance of developing an ulcer, decreases the body's response to therapy, and increases the chances of dying from ulcer complications. Blood type appears to be a predisposing factor for ulcer location; people with type A blood are more likely to have gastric ulcers, while those with type O are more likely to develop duodenal ulcers. The role of emotional **stress** in ulcer development is currently debated. Present research indicates that an individual's attitudes toward stress, rather than the amount of stress by itself, is a better predictor of vulnerability to peptic ulcers. Preferences for high-fat or spicy foods do not appear to be significant risk factors.

Gastric ulcers

The symptoms of gastric ulcers include feelings of **indigestion** and **heartburn**, weight loss, and repeated episodes of gastrointestinal bleeding. Ulcer **pain** often is described as gnawing, dull, aching, or resembling hunger pangs. The patient may be nauseated and have loss of appetite. About 30% of patients with gastric ulcers are awakened by pain at night. Many patients have periods of chronic ulcer pain alternating with symptom-free periods that last for several weeks or months. This characteristic is called periodicity.

Duodenal ulcers

The symptoms of duodenal ulcers include heartburn, stomach pain relieved by eating or **antacids**, weight gain, and a burning sensation at the back of the throat. The patient is most likely to feel discomfort two to four hours after meals, or after having citrus juice, coffee, or aspirin. About 50% of patients with duodenal ulcers awake during the night with pain, usually between midnight and 3 a.m. A regular pattern of ulcer pain associated with certain periods of day or night or a time interval after meals is called rhythmicity.

Not all digestive ulcers produce symptoms; as many as 20% of ulcer patients have so-called painless or silent ulcers. Silent ulcers occur most frequently in the elderly and in chronic NSAID users.

Diagnosis

Examination

The diagnosis of peptic ulcers should rarely be made on the basis of a **physical examination** alone. Many ulcer diagnoses based solely on physical exams actually are only **dyspepsia**, or upper adnominal pain and discomfort not caused by ulcers. The only significant finding may be mild soreness in the area over the stomach when the doctor presses (palpates) it. The doctor is more likely to suspect an ulcer if the patient has one or more of the following risk factors:

- male sex
- age over 45

- recent weight loss, bleeding, recurrent vomiting, jaundice, back pain, or anemia
- history of using aspirin or other NSAIDs
- history of heavy smoking
- family history of ulcers or stomach cancer

Tests

Blood tests usually give normal results in ulcer patients without complications. They are useful, however, in evaluating anemia from a bleeding ulcer or a high white cell count from perforation or penetration. Serum gastrin levels can be used to screen for Zollinger-Ellison syndrome.

It is important to test for *H. pylori* because almost all ulcer patients who are not taking NSAIDs are infected. Noninvasive tests include blood tests for immune response and a breath test. In the breath test, the patient is given an oral dose of radiolabeled urea. If *H. pylori* is present, it will react with the urea and the patient will exhale radiolabeled carbon dioxide. Invasive tests for *H. pylori* include tissue biopsies and cultures performed from fluid obtained by **endoscopy**.

Procedures

An endoscopy is considered the best procedure for diagnosing digestive ulcers and for taking samples of stomach tissue for biopsies. An endoscope is a slender tube-shaped instrument that allows the doctor to view the tissues lining the stomach and duodenum. Duodenal ulcers are rarely malignant. If the ulcer is in the stomach, however, the doctor will take a tissue sample because 3–5% of gastric ulcers are malignant.

Radiological studies are sometimes used instead of endoscopy because they are less expensive, more comfortable for the patient, and are 85% accurate in detecting malignancies.

Treatment

Drugs

Most drugs that are currently given to treat ulcers work either by lowering the rate of stomach acid secretion or by protecting the mucous tissues that line the digestive tract.

Medications that lower the rate of stomach acid secretions fall into two major categories: **proton pump inhibitors**, which bind an enzyme that secretes stomach acid, and H_2 receptor antagonists, which work by reducing intracellular acid secretion. The proton pump inhibitors include omeprazole (Prilosec) and lansoprazole (Prevacid). The H_2 receptor antagonists include ranitidine (Zantac), cimetidine (Tagamet), famotidine (Pepcid), and nizatidine (Axid).

The drugs that are currently used to protect the stomach tissues are sucralfate (Carafate), which forms a paste-like substance that clings to the mucous tissues and prevents further damage from stomach acid, and bismuth preparations. A third type of protective drug includes misoprostol (Cytotec), which is often given to patients with ulcers caused by NSAIDs.

Surgery

Surgical treatment of ulcers is generally used only for complications and suspected malignancies. The most common surgical procedures used are vagotomies, in which the connections of the vagus nerve to the stomach are cut in order to reduce acid secretion, and antrectomies, which involve the removal of a part of the stomach (the antrum).

Eradication of Helicobacter pylori

Most doctors presently recommend treatment to eliminate *H. pylori* in order to prevent ulcer recurrences. Without such treatment, ulcers recur at the rate of 80% per year. A 2003 report showed that eradication *H. pylori* alone usually prevents recurring bleeding ulcers. The usual regimen used to eliminate the bacterium is a combination of tetracycline, bismuth subsalicylate (Pepto-Bismol), and metronidazole (Metizol, Flagyl).

Alternative

Alternative treatments can relieve symptoms and promote healing of ulcers. A primary goal of these treatments is to rebalance the stomach's hydrochloric acid output and to enhance the mucosal lining of the stomach.

Botanical medicine offers a variety of remedies that may be helpful in ulcer treatment. Deglycyrrhizinated licorice or DGL, in a chewable or powder form, can help heal the mucous membranes and increase mucous so that it mixes with saliva to protect the membranes. Raw cabbage juice, high in glutanic acid, is very effective in healing an ulcer (one quart per day in divided doses). Soothing herbs, such as plantain (*Plantago major*), marsh mallow (*Althaea officinalis*), and slippery elm (*Ulmus fulva*); astringent herbs, such as geranium (*Pelargonium odoratissimum*); and the antimicrobial herb goldenseal (*Hydrastis canadensis*) can all be effective. Nutritionists advise taking antioxidant nutrients, including **vitamins** A, C, and E, zinc, and selenium.

Home remedies

Food allergies have been pointed to as a major cause of peptic (stomach) ulcers. An elimination/challenge diet can help identify the allergenic food(s) and continued elimination of these foods can assist in healing the ulcer. People with ulcers should not take aspirin. They also should stop smoking, since smoking irritates the mucosal lining of the stomach. Antacids should be avoided by anyone with an ulcer, because they can cause a rebound effect of increasing gastric acid secretion, as well as deplete vital nutrients necessary for healing. **Stress reduction** is also important for people with ulcers.

Prognosis

The prognosis for recovery from ulcers is good for most patients. Very few ulcers fail to respond to the medications that are currently used to treat them. Recurrences can be eliminated completely or cut to 5% by eradication of *H. pylori*. Most patients who develop complications recover without problems even when emergency surgery is necessary.

Complications

Between 10% and 20% of peptic ulcer patients develop complications at some time during the course of their illness. All of these are potentially serious conditions. Complications are not always preceded by diagnosis of or treatment for ulcers; as many as 60% of patients with complications have not had prior symptoms.

Bleeding is the most common complication of ulcers. It may result in anemia, **vomiting** blood (hematemesis), or the passage of bright red blood through the rectum (melena). About half of all cases of bleeding from the upper digestive tract are caused by ulcers. The mortality rate from ulcer hemorrhage is 6–10%.

About 5% of ulcer patients develop perforations, which are holes in the duodenal or gastric wall through which the stomach contents can leak out into the abdominal cavity. The incidence of perforation is rising because of the increased use of NSAIDs, particularly among the elderly. The signs of an ulcer perforation are severe pain, **fever**, and tenderness when the doctor touches the abdomen. Most cases of perforation require emergency surgery. The mortality rate is about 5%.

Ulcer penetration is a complication in which the ulcer erodes through the intestinal wall without digestive fluid leaking into the abdomen. Instead, the ulcer penetrates into an adjoining organ, such as the pancreas or liver. The signs of penetration are more severe pain without rhythmicity or periodicity and the spread of the pain to the lower back.

Obstruction of the stomach outlet occurs in about 2% of ulcer patients. It is caused by swelling or scar tissue formation that narrows the opening between the stomach and the duodenum (the pylorus). Over 90% of patients with obstruction have recurrent **vomiting** of partly digested or undigested food; 20% are seriously dehydrated. These patients usually feel full after eating only a little food and may lose weight.

Prevention

Strategies for the prevention of ulcers or their recurrence include the following:

- eradication of *H. pylori* in patients already diagnosed with ulcers
- giving misoprostol to patients who must take NSAIDs
- avoiding unnecessary use of aspirin and NSAIDs
- giving up smoking
- cutting down on alcohol, tea, coffee, and sodas containing caffeine

Ultrasonic lithotripsy *see* **Lithotripsy**

Ultraviolet light treatment

Definition

Ultraviolet light treatment uses a particular band of the nonvisible light spectrum to treat **psoriasis** and a variety of other skin diseases. It can be used alone or in combination with other medications applied directly to the skin or taken internally.

Purpose

Ultraviolet (UV) light treatment is used primarily in cases of severe psoriasis that have not responded to other medications or in cases affecting large portions of the body. Patients will typically receive a series of 3–5 weekly treatments for a month or more to bring their psoriasis symptoms into check. They may also receive periodic maintenance treatments to prevent recurrence of their psoriasis. Other skin conditions treated with UV light treatments are **vitiligo**, a condition in which people lose pigmentation in large patches of their skin, and **atopic dermatitis**, an allergy-related skin condition that produces itchy, reddish, and scaly patches of skin.

Precautions

Exposure to UV radiation is known to prematurely age the skin over time and increase the risk of skin **cancer**. These potential effects should be weighed against the potential benefits of the treatment. A history will be taken regarding sun exposure and burning; medications, such as **diuretics**, that may increase UV sensitivity exposure; and any history of skin cancers. Sometimes, UV light treatments are given in combination with photosensitizing agents, which maximize UV's effects on the skin. Patients who receive these agents, called psoralens, must take care to avoid exposure to sunlight, which also contains UV radiation. Exposure to UV radiation can also cause **cataracts** and other eye damage, so the patient's eyes must be adequately shielded during the treatments.

Description

UV light treatment can employ one of two bands of the ultraviolet spectrum: ultraviolet A (UVA), and ultraviolet B (UVB). Patients receive full-body treatments in special light boxes; smaller areas of the skin are sometimes treated with hand-held devices.

UVB treatment

Psoriasis is the most common skin disease treated with UVB light treatment. Its mechanism of action remains unclear, but investigators speculate it may kill abnormal skin cells or alter immune system reactions in the skin. Most patients require 18–30 treatments before substantial improvement or complete clearing is seen. The intensity of the UV applied will vary depending on the patient's skin type. Fair-skinned patients will start with a relatively weaker dose; dark-skinned patients, a stronger dose. Physicians will first expose a small area of skin to UVB to determine the minimum erythema dose (MED), the minimum amount of UVB that produces redness 24 hours after exposure. Patients will be exposed for short times early in the treatment cycle, but these times will gradually increase over time.

The Goeckerman regimen, a treatment that combines UVB light with coal tar applied to the skin, is among the oldest and most frequently used treatments for patients with moderate to severe psoriasis. The coal tar is a photosensitizing agent and when it interacts with UVB, it appears to limit the abnormal turnover of skin cells characteristic of psoriasis. Although treatments with UVB and coal tar are highly effective, many patients dislike the smell. Some investigators believe that the use of petroleum jelly or other emollients is just as effective as the coal tar preparations.

In addition to their UVB treatments, many patients will receive such systemic agents as methotrexate, a drug used in severe case of psoriasis, and certain vitamin A derivatives called retinoids. A newer retinoid called bexarotene (Targretin), which was originally developed to treat **cutaneous T-cell lymphoma**, shows promise as a treatment for psoriasis in combination with UVB therapy.

Another new development in UV therapy is the use of a laser as the source of the UVB radiation. The type of laser that is used is known as a 308-nm excimer

KEY TERMS

Erythema—The medical term for redness of the skin produced by congestion of the capillaries in the skin.

Goeckerman regimen—UVB light therapy combined with topical coal-tar preparations.

Minimum erythema dose—The minimum amount of UVB that produces redness 24 hours after exposure. It is the starting dose for UVB light treatments.

Minimum phototoxic dose—The dose of UVA that produces uniform redness 72 hours after ingesting a psoralen compound. It becomes the starting dose for PUVA treatment.

Psoralen—A family of photosensitizing chemicals that can be found in lemons, celery, and other plants. Chemically synthesized versions are used to augment the effects of UVA light treatments.

PUVA treatments—Treatments with the photosensitizers called psoralens and UVA.

Ultraviolet light—A portion of the light spectrum not visible to the eye. Two bands of the UV spectrum, UVA and UVB, are used to treat psoriasis and other skin diseases.

laser, which uses a specific mixture of gases to produce high-intensity, short pulses of UV light.

PUVA treatment

Psoralens are photosensitizing agents found in plants. They have been known since ancient Egypt but have only been available in a chemically synthesized form since the 1970s. Psoralens are taken systemically or can be applied directly to the skin. The psoralens allow a relatively lower dose of UVA to be used. When they are combined with exposure to UVA in PUVA, they are highly effective at clearing psoriasis. Like UVB light treatments, the reason remains unclear, though investigators speculate there may be similar effects on cell turnover and the skin's immune response.

Choosing the proper dose for PUVA is similar to the procedure followed with UVB. The physician can choose a dose based on the patient's skin type. Often, however, a small area of the patient's skin will be exposed to UVA after ingestion of a psoralen. The dose of UVA that produces uniform redness 72 hours later, called the minimum phototoxic dose (MPD), becomes the starting dose for treatment.

Some patients experience **nausea** and **itching** after ingesting the psoralen compound. For these patients "bath PUVA" may be a good option.

Preparation

No major preparation is required for UV light treatments. Areas of the skin that are especially sensitive to the effects of UV light, such as the groin, backside, or face, are shielded during the treatments. Areas not affected by psoriasis are also covered. Special goggles are worn to protect the eyes. Some physicians apply an emollient, such as petroleum jelly, to the skin or other topical agents, such as coal tar, to enhance the results. In PUVA treatments, the psoralen is usually taken one hour before the treatment.

Aftercare

No major aftercare is required following UV light treatments. Patients, however, must take great care to limit or eliminate other exposures to UV radiation, such as from sunlight or **tanning** beds, because of the increased risk of premature **aging** of the skin and the development of skin cancers. Patients should monitor their skin closely for any signs of precancerous or cancerous skin growths in the future.

Risks

People who receive UV light treatments are at higher risk of premature aging of the skin and of developing skin cancer. These risks should be balanced against the benefits of treatment. Patients must also take care to limit or eliminate their exposure to other sources of UV radiation, especially if they are taking a psoralen compound in addition to receiving the UV treatments.

Normal results

Psoriasis will normally show significant improvement to complete healing with three to five UVB treatments a week for about four to five weeks. PUVA treatments may require a bit longer to take effect, but because the overall dosage of UV is lower, they are thought by some investigators to be a safer alternative to UVB treatments.

Abnormal results

Modern light boxes carefully control the dosage of UV radiation and the exposure time. Overdose or

overexposure is possible, however, and can lead to severe **burns**. It is important to choose a treatment provider who is experienced in the technique. It is also important to tell the physician about all medications being taken by the patient. Some medications, either alone or in combination with a psoralen, can provoke an extreme reaction to UV radiation. One medication that has been shown to be helpful in treating burns caused by overexposure to UV radiation is a gel containing a platelet-activating antagonist factor, or PAF, known as WEB 2086.

Umbilical cord blood banking

Definition

Umbilical cord blood banking is the practice of preserving for future use fetal blood that remains in the umbilical cord at the time of birth.

Purpose

During **pregnancy**, a developing fetus is attached to its mother's placenta by the umbilical cord. At birth, this cord is cut, and the placenta is expelled from the mother. Some fetal blood remains in the umbilical cord. Normally, this blood, along with the cord and the placenta, are simply disposed of. However, now there are ways to freeze the cord blood for future use.

Umbilical cord blood is special because it contains a lot of cells called hematopoietic stem cells. A stem cell is an unspecialized master cell that can develop into several different kinds of specialized cells. Hematopoietic stem cells normally develop into red blood cells that carry oxygen, white blood cells that fight infection, and platelets that help make blood clot. These hematopoietic stem cells are *not* the same as embryonic stem cells that are at the center political and ethical debate about their use in research. Their collection does not harm either the mother or the baby.

There are two other sources of hematopoietic stem cells—bone marrow and peripheral blood. Bone marrow is the spongy material inside bones that is the source for new blood cells produced throughout an individual's life. Peripheral blood is the blood that circulates through the body.

All cells have a protein profile that identifies them. When a foreign cell enters the body, immune system cells recognize the protein profile as foreign and attack the cell. The advantage of umbilical cord stem cells that they are more immature and have a less well developed protein profile than bone marrow or peripheral stem cells. As a result, they draw a weaker response from the body's immune system.

The protein profile of human cells is called the human leukocyte antigen (HLA) profile. Normally for transplanted cells such as bone marrow cells to be accepted, there must be a close to perfect match between the HLA profile of the donor and the recipient. Since there are over 10,000 HLA types, finding an exact match can be difficult. Because umbilical cord blood cells have a less well developed HLA profile, they do not have to match the recipient's HLA as closely to be accepted by the immune system of the transplant recipient.

Types of cord blood banks

There are two types of umbilical cord blood banks—private and public. Private blood cord banks can be for-profit or not-for-profit. They sell kits that can be used at any delivery to collect cord blood. They also charge a yearly fee to store the blood. The cord blood is available only to the child or members of the

child's family from which it came. It is a perfect HLA match to child's blood. When a transplant is done using cells that came from the individual who needs the transplant, it is called an autologous transplant. Autologous transplants have a high rate of success.

Public cord banks do not charge a fee to collect or store cord blood. Parents of newborns donate the cord blood, and it is then available to anyone who needs it and is an appropriate match. This type of transplant where the recipient is not the same as the donor is called an allogeneic transplant. Much of the success of allogeneic transplants depends on finding a good HLA match. Because of funding considerations, there are a limited number of public cord blood banks. To donate to a public blood cord bank, the mother must give birth in a facility associated with a public blood cord bank.

How cord blood is used

The first successful umbilical cord **stem cell transplantation** occurred in 1988, when a newborn girl donated cord blood to cure her brother of Fanconi's anemia, a genetic defect. Many other blood diseases can now be treated successfully with cord stem cell transplants. These same diseases can be treated with bone marrow transplant if an appropriately matched donor can be found. In addition, research is ongoing in the hope that cord blood stem cells can be induced to differentiating into other types of cells, such as nerve cells, that can be used to treat other diseases.

Some diseases treated with blood stem cell transplant include:

- acute lymphatic leukemia
- acute myelogenous leukemia
- chronic myelogenous leukemia
- Hodgkin disease
- non-Hodgkin lymphoma
- neuroblastoma
- severe combined immune deficiency
- anapalstic anemia
- thalassemia
- sickle cell anemia
- Fanconi's anemia

In addition to being more readily accepted by the donor's body, cord blood offers other advantages over **bone marrow transplantation**. It is relatively quick and easy to thaw the cord blood and infuse it, while bone marrow harvesting is an invasive procedure with risks to the donor. In addition, cord blood is less likely to be contaminated with viruses that may create complications for the recipient.

Considerations in deciding to bank cord blood

Although the list of diseases treated with umbilical cord stem cells is impressive and growing, controversy exists about whether parents should pay private cord cell banks to preserve their newborn's blood. Private cord cell banks sell their services as a type of "insurance." In case the child develops a treatable disease, the child's own stem cells will be a perfect match. However, if the disease is caused by a genetic defect, (e.g., sickle cell and other **anemias**) the child's own stem cells will be useless, because they will contain the same genetic defect. In addition, the quantity of cord blood that can be collected is only enough to treat a child. Although research is being done to try to multiply cord cells in the laboratory in quantities great enough to treat an adult, results have not been successful. Therefore, if an adult develops a treatable disease, even if his own cord blood was banked, the quantity will be insufficient to produce a cure. Also, cord blood storage is a new enough technology that it is not clear how long the blood can remain frozen and still be effective.

In the most recent statement on cord blood banking released by the American Academy of Pediatrics, they concluded:

- There are no good estimates of how often a child will need a transplant of his own cells. Estimates range from 1 in 1,000 to 1 in 200,000
- Certain genetic disorders are not cured by autologous transplants
- Parents should be encouraged to donate their child's cord blood to free public cord blood banks for the widest possible use rather than paying private companies to store cord blood

The American College of Obstetricians and Gynecologists supports the position that parents should not be sold private blood cord banking without a realistic assessment of their need, nor should parents feel guilty if they are not eager or able to meet the annual expense associated with private storage. Although cord blood collection is safe, unless there is a family history of diseases for which hematopoietic stem cells are helpful, most pediatricians and obstetricians feel private cord blood storage is an unnecessary expense.

Precautions

Umbilical cord blood collection is usually not done in the case of multiple births.

Description

Cord blood collection is a simple procedure that takes between three and seven minutes. It is done

KEY TERMS

Allogeneic—A transplant where the donated material comes from different (although often related) individual than the recipient

Autologous—A transplant where the material for the transplant comes from the individual who is also the recipient; thus, the transplant material is genetically identical to the donor's body.

Hematopoietic stem cell—A cell that can develop into any type of specialized blood cell.

immediately after the baby is delivered. Cord blood is drained into a standard blood bag and then processed and frozen at very low temperatures.

Preparation

Parents who wish to bank their child's cord blood must plan ahead. Private storage requires ordering a kit in advance and coordinating with the health care providers doing the delivery to make sure the cord blood is collected properly. Mothers must test negative for infectious diseases, such as HIV and hepatitis, before delivery. Donation to a public cord blood bank is not always possible because of their limited number and location.

Aftercare

No special aftercare is required for mother or child, but the cord blood must remain frozen at low temperatures.

Risks

The main risk associated with umbilical cord blood collection is the possibility that it will become contaminated with bacteria during collection.

Parents who are interested in private cord blood storage should research the company with which they contract, just as they would in making any business decision. They need to know the costs, whether the annual fee can increase, and what will happen to the blood if the company goes out of business.

Umbilical hernia repair

Definition

An umbilical **hernia repair** is a surgical procedure performed to fix a weakness in the abdominal wall or to close an opening near the umbilicus (navel) that has allowed abdominal contents to protrude. The abdominal contents may or may not be contained within a membrane or sac. The medical name for a hernia repair is herniorrhaphy.

Purpose

Umbilical hernias are usually repaired either to relieve discomfort or to prevent complications. It is not always necessary to fix an umbilical hernia. If the person is not in **pain**, the hernia is often not repaired. Complications may develop if pressure inside the abdomen resulting from daily activity pushes the abdominal contents further through the opening. They may then become twisted or strangulated. Strangulation is a condition in which the circulation to a section of the intestine (or other part of the body) is cut off by compression or constriction; it can cause extreme pain. If the

KEY TERMS

Abdominal distension—Swelling of the abdominal cavity, which creates painful pressure on the internal organs.

Hernia—The protrusion of a loop or piece of tissue through an incision or abnormal opening in other tissues.

Herniorraphy—The medical name for a hernia repair procedure.

Incarceration—The abnormal confinement of a section of the intestine or other body tissues. An umbilical hernia may lead to incarceration of part of the intestine.

Intra-abdominal pressure—Pressure that occurs within the abdominal cavity. Pressure in this area builds up with coughing, crying, and the pressure exerted when bearing down with a bowel movement.

Strangulation—A condition in which a vessel, section of the intestine, or other body part is compressed or constricted to the point that blood cannot circulate.

Umbilicus—The area where the umbilical cord was attached; also known as the navel or belly button.

strangulation persists, the tissue can die from lack of blood supply and lead to an infection.

Demographics

An umbilical hernia can occur in both men and women and can occur at any age, although it is often present at birth. Umbilical hernias are found in about 20% of newborns, especially in premature infants. Umbilical hernias are more common in male than in female infants; with regard to race, they are eight times more common in African Americans than in Caucasians or Hispanics. While umbilical hernia is not a genetically determined condition, it tends to run in families. In the adult population, umbilical hernias are more common in overweight persons with weak abdominal muscles and in women who are either pregnant or have borne many children. People with **liver disease** or fluid in the abdominal cavity are also at higher risk of developing an umbilical hernia.

Description

Repair of an abdominal hernia involves a cut, or incision, in the umbilical area. Most herniorrhaphies take about two hours to complete. After the patient has been given a sedative, the anesthesiologist will administer a local, spinal, or general anesthetic. The type of anesthesia used depends on the patient's age, general health, and complexity of the procedure. The incision is usually made underneath the belly button. The herniated tissues are isolated and pushed back inside the abdominal cavity. A hernia repair may be done using traditional open surgery or with a laparoscope. A laparoscopic procedure is performed through a few very small incisions. The hole in the abdominal wall may be closed with sutures, or by the use of a fine sterile surgical mesh. The mesh provides additional strength. Some surgeons may choose to use the mesh when repairing a larger hernia. A hernia repair done with a mesh insert is called a tension-free procedure because the surgeon does not have to put tension on the layer of muscle tissue in order to bring the edges of the hole together.

Diagnosis/Preparation

Diagnosis

In children, umbilical hernias are often diagnosed at birth, usually when the doctor feels a lump in the area around the belly button. The hernia may also be diagnosed if the child is crying from pain, because the crying will increase the pressure inside the abdomen and make the hernia more noticeable.

Umbilical hernias in adults occur more often in pregnant women and obese persons with weak stomach muscles. They may develop gradually without producing any discomfort, but the patient may see a bulge in the abdomen while bathing or getting dressed. Other patients consult their doctor because they have felt the tissues in the abdomen suddenly give way when they are having a bowel movement. In an office examination, the patient may be asked to lie down, lift the head, and **cough**. This action increases pressure inside the abdomen and causes the hernia to bulge outward.

A hernia that has become incarcerated or strangulated is a medical emergency. Its symptoms include:

- nausea
- vomiting
- abdominal swelling or distension
- pale complexion
- weakness or dizziness
- extreme pain

When a hernia is present at birth, some surgeons may opt for a "wait and see" approach, as umbilical hernias in children often close by themselves with time.

If the hernia has not closed by the time the child is three or four years old, then surgery is usually considered. If the hernia is very large, surgery may be recommended.

Repair of an umbilical hernia in an adult is usually considered elective surgery. The patient's surgeon may recommend the procedure, however, on the grounds that hernias in adults do not close by themselves and tend to grow larger over time.

Preparation

Adults scheduled for a herniorraphy are given standard blood tests and a **urinalysis**. They should not eat breakfast on the morning of the procedure, and they should wear loose-fitting, comfortable clothing that they can easily pull on after the surgery without straining their abdomen.

Aftercare

Aftercare will depend in part on the invasiveness of the surgery, whether laparoscopic or open; the type of anesthesia; the patient's age; and his or her general medical condition. Immediately after the procedure, the person will be taken to the recovery area of the surgical center, where nurses will monitor the patient for signs of excessive bleeding, infection, uncontrolled pain, or **shock**. Hernia repairs are usually performed on an outpatient basis, which means that the patient can expect to go home within a few hours of the surgery. Adult patients, however, should arrange to have a friend or relative drive them home. If possible, someone should stay with them for the first night.

The nurses will provide the patient with instructions on incision care. The specific instructions will depend on the type of surgery and the way in which the incision was closed. Sometimes a see-through dressing is placed on the wound that the patient can remove about three days after the procedure. It may be necessary to keep the dressing dry until some healing has taken place. Very small incisions may be closed with Steri-strips rather than sutures.

Risks

There are surgical and anesthesia-related risks with all surgical procedures. The primary surgical risks include bleeding and infection. Anesthesia-related risks include reactions to the specific anesthetic agents that are used; interactions with over-the-counter and herbal preparations; and respiratory problems. The greatest risk associated with umbilical hernia is missing the diagnosis. Additional risks include the formation of scar tissue and recurrence of the hernia.

Normal results

Umbilical hernia repair is usually considered an uncomplicated procedure with a relatively short recovery period. A study reported in the December 2002 issue of the *American Journal of Surgery* found that patients who had laparoscopic surgery with the use of a surgical mesh had fewer complications and reoccurrences of a hernia than those with the traditional open surgery. However, laparoscopic surgery took somewhat longer to perform, possibly because the laparoscopic approach is often used for larger repairs.

Morbidity and mortality rates

In general, there are few complications with hernia repair in children. The most serious complication is surgical injury to the bladder or intestine; fortunately, this complication is very rare—about one in 1,000 patients. The recurrence rate is between 1% and 5%; recurrence is more likely in patients with very large hernias. The rate of infection is less than 1%. In the adult population, a November 2001 study reported in the *American Journal of Surgery* found a 5% mortality in elderly patients undergoing emergency hernia repairs.

Alternatives

There are no medical or surgical alternatives to an umbilical hernia repair other than watchful waiting. Since umbilical hernias present at birth often close on their own, intervention can often be delayed until the child is several years old. There is some risk that the hernia will enlarge, however, which increases the risk of incarceration or strangulation.

Undernutrition

Definition

Undernutrition is the result of inadequate intake of calories, protein, or micronutrients. Although undernutrition and **malnutrition** often are used interchangeably, malnutrition is a more inclusive term that includes overnutrition.

Demographics

The United Nations Children's Fund (UNICEF) estimates that about 195 million children have stunted growth as a direct result of undernutrition. Of these, about 90% are in Africa and Asia. India has the largest absolute number of stunted children, while Afghanistan has the highest percentage of stunted children. Undernutrition is uncommon in the developed world, but the British Nutrition Foundation estimates that about two million people in the United Kingdom are undernourished. Undernutrition has the most severe impact on children under age five.

Undernutrition in children is much less common in the United States than in developing countries. Estimates suggest that only about 1% of all children in the United States experience undernutrition. The highest risk children in the United States are those living in homeless shelters, where an estimated 10% of children are undernourished. Estimates also suggest that one in every seven elderly individuals in the United States consume fewer than 1,000 calories per day and are undernourished.

Description

Undernutrition is a serious problem in developing countries, especially in children under age five years. Undernutrition can begin before a baby is born. Deficiencies in calories, protein, **minerals**, and/or **vitamins** often affect the fetus during **pregnancy** because the mother does not consume enough calories and micronutrients. This often results in the delivery of a low birthweight baby. According to the World Health Organization (WHO), low birthweight accounts for about 60% of deaths in newborns in developing countries or 3.3% of all child deaths.

Undernutrition frequently continues into early childhood. There is a strong relationship between undernutrition and failure to survive. Children may not directly starve to **death** from undernutrition, although some do die of disorders such as marasmus, which is a severe deficiency in calories and protein. Instead, undernourished children tend to have weak immune systems that leave them highly susceptible to common diseases such as **diarrhea**, **pneumonia**, **malaria**, and **measles**, all of which are common in the developing world. Often, undernourished children go through a downward cycle of repeated disease and recovery before they die; if they do survive, this cycle exacts a heavy toll on their development. Exact figures are difficult to obtain from developing countries, but estimates suggest that maternal and child undernutrition is the cause of 3–5 million deaths annually. Zinc and **vitamin A deficiency** are the most common micronutrient deficiencies, while iron and iodine deficiencies also contribute to undernutrition.

A critical window for development exists between birth and age two years. Even when children survive these critical years, the effects of undernutrition remain. Often these children are stunted (short stature) or wasted (seriously underweight). In addition to physical effects, undernutrition can restrict a child's mental development.

Undernutrition in the elderly is a greater problem in the United States than undernutrition in children. Declining appetite, limited funds, difficulty in preparing and eating food, and disease all contribute to undernutrition in the elderly. Elderly people living in nursing homes or hospitalized for prolonged periods are at high risk for undernutrition. Any age individuals who have had **gastric bypass** surgery may experience undernutrition unless they take prescribed vitamin and mineral supplements.

Risk factors

Risk factors for undernutrition include inadequate food supply (e.g., famine), inadequate variety of food (i.e., food does not contain all the required micronutrients), living in a war zone, poverty, low maternal

KEY TERMS

Micronutrients—Minerals and vitamins needed in small quantities to maintain health (e.g., iodine).

Stunting—A height more than two standard deviations from the median height for the age in the reference population.

Wasting—Weight more than two standard deviations below that of the median weight for the reference population.

status, poor **breastfeeding** habits, and cultural attitudes (e.g., boy infants may be fed more than girl infants).

Homelessness is a major cause of undernutrition in the United States, as is **alcoholism**. Diseases such as depression or other mental illness can cause individuals to stop eating or to refuse to eat a variety of foods. Certain medications can also inhibit the uptake of nutrients from the digestive system, resulting in undernutrition. Certain diseases, such as some cancers and **AIDS,** can cause the body to increase the amount of calories used, resulting in severe wasting, called cachexia.

Causes and symptoms

The root cause of undernutrition is inadequate intake of calories, protein, and micronutrients. Secondary causes are the same as the risk factors previously described.

Symptoms of undernutrition in children include low birth weight, stunting, wasting, low energy level, slowed physical development, impaired mental development, and frequent serious illnesses. In the elderly, undernutrition can cause weight loss, thinning and drying of the skin, hair loss, constantly feeling cold, confused thinking, frequent falls, and frequent infections. These symptoms often go unrecognized and are attributed to a general decline due to **aging**.

Diagnosis

Examination

Diagnosis is most often made by examination and by comparing the height and weight of the individual to the median height and weight of the reference population. The physician will review drugs the individual is taking and ask questions about alcohol and food consumption.

Tests

A **complete blood count** (CBC) generally is done to assess the individual's general health and to look for signs of infections. Blood tests may be done to measure the amount of albumin in the blood. Albumin is a blood protein that decreases when there is an inadequate amount of protein in the diet. Additional tests may be done when a specific vitamin or **mineral deficiency** is suspected.

Treatment

The only treatment for undernutrition is to increase calories and protein and to replace the micronutrients missing from the diet. In healthcare settings, such as a nursing home or hospital, this can be done in consultation with a registered dietitian. Long-term success in reducing undernutrition generally requires overcoming the barriers that prevent the individual from getting enough calories and enough food variety. This may involve:

- treating any underlying disease or mental condition contributing to the undernutrition
- overcoming barriers to food preparation, for example by enrolling the individual in Meals on Wheels
- providing a wide range of nutritious food through meals for the homeless, the establishment of inner city farmers's markets, or providing transportation to local food banks
- using drugs to stimulate the appetite
- enrolling individuals in food support programs such as Women Infants and Children (WIC), the Supplementary Nutrition Program (SNAP, formerly food stamps), and the Federal School Lunch program in the United States

Individuals who cannot eat, for example those who cannot swallow because they have had a **stroke**, may be fed through a tube inserted into the nose and down the esophagus to the stomach. Individuals who do not absorb enough nutrients from the digestive tract may be fed intravenously (**total parenteral nutrition**). Both these feeding methods have drawbacks and potentially serious side effects.

Prognosis

Some early effects of undernutrition cannot be reversed. Consistent undernutrition before birth and during the first five years of life often leads to childhood death. In survivors, it has permanent physical and developmental effects. Even if the child later receives adequate nutrition, he or she may remain short of

stature and have permanent cognitive deficits. Undernutrition during pregnancy can lead to **miscarriage**, premature delivery, a low birthweight baby, maternal susceptibility to disease, and maternal death. Undernutrition in the elderly results in more frequent and more severe illness and infection.

Prevention

The problem of preventing undernutrition is complex. Many international aid agencies work to prevent undernutrition, especially undernutrition in children. Their goal is to eventually help developing countries develop adequate food resources for the entire population. To do this, they must overcome food delivery, storage, and distribution problems; regional warfare; poverty; illiteracy; and cultural attitudes. UNICEF and WHO have made reducing child undernutrition one of their priorities for the twenty-first century.

Exclusive breastfeeding for at least six months with supplemental breast feeding until age two is recommended for all babies. This is especially important in developing countries where supplies of clean water and adequate infant food are limited. According to WHO, appropriately breastfed children in developing countries are six times more likely to survive to age five than those who are not breast fed.

In the United States, treating homelessness, alcoholism, and drug **abuse**, as well as educating individuals about food security programs that are available to them, are the most effective ways of preventing undernutrition.

Undescended testes

Definition

Also known as cryptorchidism, undescended testes is a congenital condition characterized by testicles that do not extend to the scrotum. This condition is the most common male sexual development abnormality.

Demographics

Thirty percent of premature boys have testes that have not yet made the full descent. Only 3–5% of full-term baby boys have undescended testes, and half of those complete the journey by the age of four months. Most cases, about 97% to 99%, of undescended testes naturally correct themselves during the first year of life. Spontaneous descent, however, does not seem to occur after age 9 months.

Description

In the fetus, the testes are in the abdomen. As development progresses they migrate downward through the groin and into the scrotum. This event takes place late in fetal development, during the eighth month of gestation. Undescended testes that are not corrected can lead to sterility, **testicular torsion** and an increased risk of **testicular cancer**.

Causes and symptoms

The cause of undescended testes is presently unknown. However, its symptoms are quite apparent. One or both of the testicles can be undescended,

KEY TERMS

Cryptorchidism—Undescended testes.

Embryonic—Early stages of life in the womb.

Fetal—Refers to the fetus, also known in the first two months after conception as an embryo.

Orchiopexy—Surgical procedure that places the testicles in the scrotum.

therefore the testicles appear to be either missing or lopsided.

Undescended testicles are more likely to occur in boys of low birth weight, from twin pregnancies, and in small babies. Maternal estrogen exposure seems to play a role in cryptorchidism. Cryptorchidism is also associated with the following conditions:

- inguinal hernia
- hypospadias
- cerebral palsy
- mental retardation and Down syndrome
- Wilms tumor
- prune belly syndrome and Prader-Willi syndrome

Diagnosis

Examination

The newborn examination always includes checks for testes in the scrotum. It they are not found, a search will be conducted, but not necessarily right away. In most cases, the testes will drop into place later. If the testes are present at all, they can be anywhere within a couple of inches of the appropriate spot. In 5% of cases, one testis is completely absent. In 10%, the condition occurs on both sides.

The patient should be examined in a warm location and should be as relaxed as possible. The examination begins with a visual inspection prior to manual palpation. The patient may be placed in the frog-leg or catcher position to facilitate the examination. The preferred examination technique is to begin palpating at the level of the inguinal canal and to perform a milking motion down until the level of the scrotum. If the testicle cannot be located in the inguinal area, examination of the penis, femoral and perineal areas are conducted as occasionally the testicle may be found in those locations.

Tests

If the testes are unable to be palpated or if there is unilateral or bilateral undescended testes, chromosomal testing and measurement of multiple hormone levels may be indicated.

Procedures

Diagnostic **laparoscopy** may be implemented for localizing testis which can not be palpated. This procedure is often combined with definitive therapy such as laparoscopic or open orchiopexy.

Treatment

Once it is determined that the testes will not naturally descend, surgery becomes necessary. The procedure is called an orchiopexy and is relatively simple once the testes are located. The surgery is usually performed when the boy is between one and two years old. Early surgical intervention, prior to age one, seems to be of most benefit.

In Europe, hormonal therapy, utilizing human chorionic gonadotropin and/or leuteinizing releasing hormones, has been used for many years to treat cryptorchidism especially in patients who may not be candidates for surgical intervention.

Prognosis

Orchiopexy conducted prior to age two years has been shown to result in less damage to the testis and may also improve viability of sperm. Currently, orchiopexy prior to age 1 is recommended.

In men with undescended testes the risk for developing testicular **cancer** is 3–5% which is 4 to 7 times higher than when compared to the risk for men without this condition. Surgical intervention does not protect against the development of subsequent testicular cancer but it does place the testis in a more accessible anatomical position to facilitate routine self-evaluation and for clinical evaluation purposes.

Men with a history of bilateral undescended testicles tend to have a higher **infertility** rate when compared to men with unilateral cryptorchidism or with men in the general population. Men with bilateral undescended testicles have a 60% paternity rate while men with a unilateral undescended testicle have 90% paternity rate as compared to the paternity rate of 94% of men in the general population.

Upper GI exam

Definition

An upper GI examination is a fluoroscopic examination (a type of x-ray imaging) of the upper gastrointestinal tract, including the esophagus, stomach, and upper small intestine (duodenum).

Purpose

An upper GI series is frequently requested when a patient experiences unexplained symptoms of abdominal **pain**, difficulty in swallowing (dysphagia), regurgitation, **diarrhea**, or weight loss. It is used to help diagnose disorders and diseases of, or related to, the upper gastrointestinal tract, including cases of **hiatal hernia**, diverticuli, ulcers, tumors, obstruction, enteritis, **gastroesophageal reflux disease**, **Crohn's disease**, and pulmonary aspiration.

Precautions

Because of the risks of radiation exposure to the fetus, pregnant women are advised to avoid this procedure. Patients with an obstruction or perforation in their bowel should not ingest barium (a radioactive substance used to show contrast in the images) for an upper GI, but may still be able to undergo the procedure if a water-soluble contrast medium is substituted for the barium.

Glucagon, a medication sometimes given prior to an upper GI procedure, may cause **nausea** and **dizziness**.

Description

An upper GI series takes place in a hospital or clinic setting and is performed by an x-ray technician and a radiologist. A radiologist typically is in attendance to oversee the procedure, and view and interpret the fluoroscopic pictures. Before the test begins, the patient is sometimes administered an injection of glucagon, a medication which slows stomach and bowel activity, to allow the radiologist to get a clearer picture of the gastrointestinal tract. In order to further improve the clarity of the upper GI pictures, the patient may be given a cup of baking soda crystals to swallow, which distend the stomach by producing gas.

Once these preparatory steps are complete, the patient stands against an upright x-ray table, and a fluoroscopic screen is placed in front of him. The patient will be asked to drink from a cup of flavored barium sulfate, a thick and chalky-tasting liquid that allows the radiologist to see the digestive tract, while the radiologist views the esophagus, stomach, and duodenum on the fluoroscopic screen. The patient will be asked to change positions frequently in order to coat the entire surface of the gastrointestinal tract with barium. The technician or radiologist may press on the patient's abdomen in order to spread the barium. The x ray table will also be moved several times throughout the procedure. The radiologist will ask the patient to hold his breath periodically while exposures are being taken. The entire procedure takes approximately 30 minutes.

In some cases, in addition to the standard upper GI series, a doctor may request a detailed intestine, or small bowel, radiography and fluoroscopy series; it is also called a small bowel follow-through (SBFT). Once the preliminary upper GI series is complete, the patient will be escorted to a waiting area while the barium travels down through the rest of the small intestinal path. Every 15–30 minutes, the patient will return to the x-ray suite for additional x rays, or films. Once the barium has completed its trip down the small bowel tract, the test is completed. This procedure can take anywhere from one to four hours.

Esophageal radiography, also called a barium esophagram or a barium swallow, is a study of the esophagus only, and is usually performed as part of the upper GI series. It is commonly used to diagnose the cause of difficulty in swallowing (dysphagia) and for detecting

hiatal hernia. A barium sulfate liquid, and sometimes pieces of food covered in barium, are given to the patient to drink and eat while a radiologist examines the swallowing mechanism on a fluoroscopic screen. The test takes approximately 30 minutes.

Preparation

Patients must not eat, drink, or smoke for eight hours prior to undergoing an upper GI examination. Longer dietary restrictions may be required, depending on the type and diagnostic purpose of the test. Patients undergoing a small bowel follow-through exam may be asked to take **laxatives** the day prior to the test. Upper GI patients are typically required to wear a hospital gown, or similar attire, and to remove all jewelry, so the camera has an unobstructed view of the abdomen.

Aftercare

No special aftercare treatment or regimen is required for an upper GI series. The patient may eat and drink as soon as the test is completed. The barium sulfate may make the patient's stool white for several days, and patients are encouraged to drink plenty of fluids in order to eliminate it from their system.

Risks

Because the upper GI series is an x-ray procedure, it does involve minor exposure to ionizing radiation. Unless the patient is pregnant or multiple radiological or fluoroscopic studies are required, the small dose of radiation incurred during a single procedure poses little risk. However, multiple studies requiring fluoroscopic exposure that are conducted in a short time period have been known, on rare occasions, to cause skin **death** (necrosis) in some individuals. This risk can be minimized by careful monitoring and documentation of cumulative radiation doses administered to these patients.

Normal results

A normal upper GI series will show a healthy, functioning, and unobstructed digestive tract.

Abnormal results

Obstructions or inflammation, including ulcers of the esophagus, stomach, or small intestine, or irregularities in the swallowing mechanism are just a few of the possible abnormalities that may show up on an upper GI series.

Urea clearance by the kidneys *see* **Kidney function tests**

Ureteral stenting

Definition

Ureteral stents are thin catheters threaded into segments of the ureter that carry urine, produced by the kidney, either down into the bladder internally, or to an external collection system. Insertion is most often done through the skin (percutaneously); however, in the presence of kidney or ureteral stones, stenting is ideally done during **cystoscopy**.

Purpose

Ureteral stenting may be placed on a long-term basis (months to years) in order to bypass ureteral obstruction. Short-term stenting (weeks to months) may be used as an adjunct to open surgical procedures of the urinary tract to provide a mold around which healing can occur, or to divert the urinary flow away from areas of leakage. Following balloon dilation or incision of ureteral strictures, placement of stents maintains the functionality of the ureters. Stents may also be used in the presence of **kidney stones** to manipulate or prevent stone migration prior to treatment or to make the ureters more easily identifiable during difficult surgical procedures. Ureteral stents may be used in those with active kidney infection or with markedly diseased, intolerant bladders (e.g., damage from **radiation therapy**, bladder invasion by adjacent neoplasm).

Preparation

The procedure should be thoroughly explained by a medical professional before it takes place. The patient will be asked to put on a hospital gown. If the procedure is performed with the aid of a cytoscope, the patient will assume a position that is typically used in a gynecological exam.

KEY TERMS

Cystoscopy—Examination or treatment of the interior of the urinary bladder by looking through a special instrument with reflected light.

Stricture—An abnormal narrowing of a tube or passageway.

Ureter—The tube-like passageway in the body that carries urine from the kidney to the bladder.

Aftercare

Stents must be periodically replaced to prevent **fractures** within the catheter wall or buildup of encrustation. Stent replacement is recommended approximately every six months or more often in patients who form stones.

Normal results

Normally, a ureteral stent assures the patient of a free flow of urine. Postoperatively, urine flow will be monitored to ensure the stent has not been dislodged or obstructed.

Abnormal results

Serious complications of the procedure occur in approximately four percent of cases, with minor complications in another 10%. These may include:

- Bleeding. Usually minor and easily treated, occasionally requiring transfusion
- Catheter migration or dislodgement. May require readjustment with the fluoroscope in the Radiology Department
- Coiling of the stent within the ureter. May cause lower abdominal pain or flank pain on urination, urinary frequency, or blood in the urine
- Introduction or worsening of infection
- Penetration of adjacent organs (e.g., bowel, gallbladder, or lungs)

Urethra defects *see* **Hypospadias and epispadias**

Urethritis

Definition

Urethritis is an inflammation of the urethra that is usually caused by an infection.

Description

The urethra is the canal that moves urine from the bladder to the outside of the body. When this canal becomes infected, inflammation occurs due to the accumulation of white blood cells in the area. When this occurs, it is called urethritis. Besides the urethra, the urinary tract consists of the bladder, ureters, and kidneys. Inflammation can move up the urethra, causing **cystitis** in the bladder, or **nephritis** in the kidneys. Collectively, these inflammations are called urinary tract infections or UTIs.

Urinary tract infections are much more common in women than in men, probably due to anatomy. Infections are especially more common in older women, due to bladder problems.

Causes and symptoms

Uncomplicated urethritis usually results from infection by the bacteria ***Escherichia coli***, commonly found in the bowel. Complicated urethritis can occur when other problems exist, such as **kidney stones**, malformations of the urinary tract, **spinal cord injury**, or a compromised immune system. People with diabetes tend to have more urinary tract infections, as well as hospitalized patients. Urinary tract infections can also be sexually transmitted. Some people seem to be susceptible to urinary tract infections, having them recurrently.

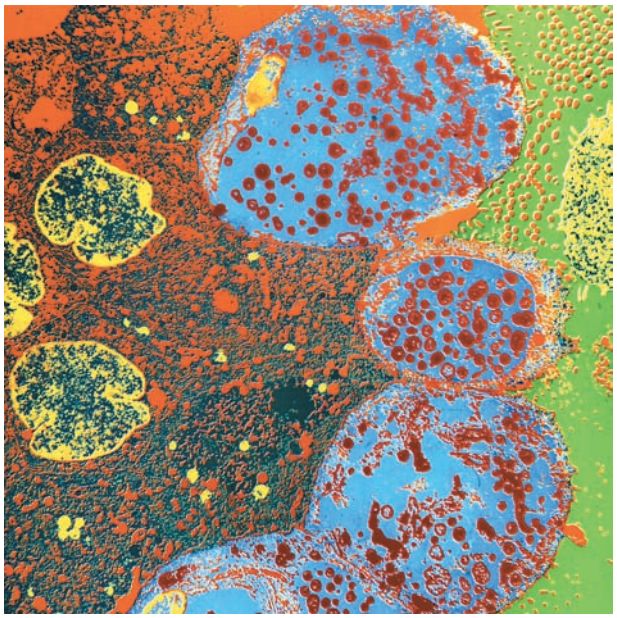
Frequently, a **urinary tract infection** has no symptoms. Common symptoms though, include **pain** and a burning sensation when urinating, frequent urination, or passing blood in the urine. Signs that the infection may be worsening include **fever** and chills, **nausea**, **vomiting**, and lower back pain.

Diagnosis

The diagnosis for a urinary tract infection is made by assessing the symptoms, feeling (palpating) the abdomen for tenderness, and a **urinalysis**. A urinalysis, or urine sample, is examined for both the presence of bacteria and white blood cells. After this, a **urine culture** to determine what bacteria is causing the infection may be done.

Treatment

Typical treatment for urinary tract infections is a course of **antibiotics**. In women who have recurrent



A false color transmission electron micrograph (TEM) scan of non-specific urethritis. *(Custom Medical Stock Photo, Inc. Reproduced by permission.)*

urethritis, the diagnosis and treatment is often resolved over the phone. Additional drugs are sometimes given to relieve discomfort.

Alternative treatment

For those individuals who seem to be more susceptible to urinary tract infections, drinking lots of fluids at the first sign of an infection can ward it off by diluting the bacteria present and flushing the system. Adding a teaspoon of baking soda to a glass of water and drinking it can change the pH of the urine, causing it to burn less. Also, cranberry juice contains a compound that can prevent bacteria from sticking to and thus growing in the urinary tract. Antimicrobial herbs, such as uva ursi (*Arctostaphylos uva-ursi*) and pipsissewa (*Chimaphila umbellata*), may be helpful. Other herbs, such as marsh mallow (*Althaea officinalis*), slippery elm (*Ulmus fulva*), comfrey (*Symphytum officinale*), plantain (*Plantago major*), and cornsilk, can soothe the urinary tract. *Lactobacillus acidophilus* and *L. bifidus* supplementation reintroduces normal flora into the urinary tract. **Acupuncture** and homeopathy can also be effective therapies for urethritis.

Prognosis

Given the appropriate antibiotic, urinary tract infections usually go away quickly. If not treated soon enough, however, urethritis can move up the urinary tract, infecting the bladder and possibly the kidneys, resulting in kidney damage. If the infection moves into the blood, additional complications can arise. Those who have previously had a urinary tract infection are more susceptible to additional urinary tract infections. Because of this, patients need to be aware of the symptoms so that a physician can be notified if the infection becomes recurrent.

Prevention

There are some steps that can be taken to keep the urinary tract healthy and prevent infection:

- drink plenty of fluids
- do not hold urine once the urge to urinate has occurred
- after a bowel movement, wipe from front to rear to keep bowel bacteria at a distance
- wear cotton underwear
- rinse soap off well in the shower
- urinate after sexual intercourse
- for post-menopausal women, estrogen replacement therapy can help prevent urinary tract infection

Cindy L. A. Jones, PhD

Uric acid tests

Definition

Uric acid tests are tests that are done to measure the levels of uric acid in blood serum or in urine.

Purpose

Uric acid tests are used to evaluate the blood levels of uric acid for **gout** and to assess uric acid levels in the urine for kidney stone formation. The urine test is used most often to monitor patients already diagnosed with **kidney stones**, but it can also be used to detect disorders that affect the body's production of uric acid and to help measure the level of kidney functioning.

Uric acid is a waste product that results from the breakdown of purine, a nucleic acid. (Nucleic acids are

KEY TERMS

Fanconi's syndrome—A rare disorder caused by vitamin D deficiency or exposure to heavy metals.

Gout—A metabolic disorder characterized by sudden recurring attacks of arthritis caused by deposits of crystals that build up in the joints due to abnormally high uric acid blood levels. In gout, uric acid may be overproduced, underexcreted, or both.

Hyperuricemia—Excessively high levels of uric acid in the blood, often producing gout.

Purine—A white crystalline substance that is one of the building blocks of DNA. Uric acid is produced when purine is broken down in the body.

Uric acid—A compound resulting from the body's breakdown of purine. It is normally present in human urine only in small amounts.

Uricosuria—Increased levels of uric acid in the urine.

Wilson's disease—A rare hereditary disease marked by the buildup of copper in the liver and brain, causing loss of kidney function.

the building blocks of DNA.) Uric acid is made in the liver and excreted by the kidneys. If the liver produces too much uric acid or the kidneys excrete too little, the patient will have too much uric acid in the blood. This condition is called hyperuricemia. Supersaturated uric acid in the urine (uricosuria) can crystallize to form kidney stones that may block the tubes that lead from the kidneys to the bladder (the ureters).

Precautions

Blood test

Patients scheduled for a blood test for uric acid should be checked for the following medications: loop **diuretics** (Diamox, Bumex, Edecrin, or Lasix); ethambutol (Myambutol); vincristine (Oncovin); pyrazinamide (Tebrazid); thiazide diuretics (Naturetin, Hydrex, Diuril, Esidrix, HydroDiuril, Aquatensen, Renese, Diurese); **aspirin** (low doses); **acetaminophen** (Tylenol); ascorbic acid (vitamin C preparations); levodopa (Larodopa); or phenacetin. These drugs can affect test results.

Certain foods that are high in purine may increase the patient's levels of uric acid. These include kidneys, liver, sweetbreads, sardines, anchovies, and meat extracts.

Urine test

Patients should be checked for the following medications before the urine test: diuretics, aspirin, pyrazinamide (Tebrazid), phenylbutazone, probenecid (Benemid), and allopurinol (Lopurin). If the patient needs to continue taking these medications, the laboratory should be notified.

The laboratory should also be notified if the patient has had recent x ray tests requiring contrast dyes. These chemicals increase uric acid levels in urine and decrease them in blood.

Description

The uric acid blood test is performed on a sample of the patient's blood, withdrawn from a vein into a vacuum tube. The procedure, which is called a venipuncture, takes about five minutes. The urine test requires the patient to collect all urine voided over a 24-hour period, with the exception of the very first specimen. The patient keeps the specimen container on ice or in the refrigerator during the collection period.

Preparation

The uric acid test requires either a blood or urine sample. For the blood sample, the patient should be **fasting** (nothing to eat or drink) for at least eight hours before the test. The urine test for uric acid requires a 24-hour urine collection. The urine test does *not* require the patient to fast or cut down on fluids. Some laboratories encourage patients to drink plenty of fluids during the collection period.

Risks

Risks for the blood test are minimal, but may include slight bleeding from the puncture site, a small bruise or swelling in the area, or **fainting** or feeling lightheaded.

Normal results

Blood test

Reference values for blood uric acid vary from laboratory to laboratory but are generally found within the following range: Male: 2.1–8.5 mg/dL; female: 2.0–6.6 mg/dL. Values may be slightly higher in the elderly.

Urine test

Reference values for 24-hour urinary uric acid vary from laboratory to laboratory but are generally found within the following range: 250–750 mg/24 hours.

Abnormal results

The critical value for the blood test is a level of uric acid higher than 12 milligrams per deciliter (about 3.4 ounces).

Increased *production* of uric acid may result from eating foods that are high in purine. Increased uric acid levels due to overproduction may also be caused by gout, by a genetic disorder of purine metabolism, or by metastatic **cancer**, destruction of red blood cells, leukemia, or cancer **chemotherapy**.

Decreased *excretion* of uric acid is seen in chronic **kidney disease**, low thyroid, toxemia of **pregnancy**, and **alcoholism**. Patients with gout excrete less than half the uric acid in their blood as other persons. Only 10-15% of the total cases of hyperuricemia, however, are caused by gout.

Abnormally low uric acid levels may indicate that the patient is taking allopurinol or probenecid for treatment of gout; may be pregnant; or suffers from Wilson's disease or **Fanconi's syndrome**.

Janis O. Flores

Urinalysis

Definition

Urinalysis is a diagnostic physical, chemical, and microscopic examination of a urine sample (specimen). Specimens can be obtained by normal emptying of the bladder (voiding) or by a hospital procedure called catheterization.

Purpose

Urinalyses are performed for several reasons:

- general evaluation of health
- diagnosis of metabolic or systemic diseases that affect kidney function
- diagnosis of endocrine disorders. Twenty-four hour urine studies are often ordered for these tests.
- diagnosis of diseases or disorders of the kidneys or urinary tract
- monitoring of patients with diabetes
- testing for pregnancy
- screening for drug abuse

Precautions

Voided specimens

Urinalysis should not be performed while a woman is menstruating or having a vaginal discharge. A woman who must have a urinalysis while she has a vaginal discharge or is having her period should insert a fresh tampon before beginning the test. She should also hold a piece of clean material over the entrance to her vagina to avoid contaminating the specimen.

Patients do not have to fast or change their food intake before a urine test. They should, however, avoid intense athletic training or heavy physical work before the test because it may result in small amounts of blood in the urine.

The following drugs can affect urinalysis results. The patient may be asked to stop taking them until after the test:

- nitrofurantoin (Macrodantin, Furadantin), prescribed for infections of the urinary tract and other bacterial infections
- phenazopyridine (Pyridium), used to relieve burning and pain caused by urinary tract infections
- rifampin (Rifadin), prescribed to treat tuberculosis, prevent the spread of meningitis, and treat other infections

Bladder catheterization

Bladder catheterization is sometimes used to collect urine samples from hospitalized patients. It should not, however, be used to collect specimens from males with acute inflammation of the prostate or from a patient of either sex with a fractured pelvis.

Description

Collecting a urine sample from emptying the bladder takes about two or three minutes. The sample can be collected at home as well as in a doctor's office. Urine specimens are usually collected early in the morning before breakfast. Urine collected eight hours after eating and at least six hours after the most recent

urination is more likely to indicate abnormalities. Some people may be asked to void into a clean container before getting out of bed in the morning.

Specimen containers

The doctor or hospital will supply a sterile container for a specimen being collected for a colony count. A colony count is a test that detects bacteria in urine that has been cultured for 24–48 hours. It is used instead of a routine urinalysis when a patient's symptoms suggest a **urinary tract infection**. Nonsterile containers can be used for routine specimens that will not be tested immediately after being collected. An ordinary open-necked jar may be used after it and its lid have been soaked in very hot water for 15–20 minutes and then air-dried.

Laboratory procedures

STORAGE. Urine specimens should not remain unrefrigerated for longer than two hours. A urine specimen that cannot be delivered to a laboratory within two hours should be stored in a refrigerator. The reason for this precaution is that urine samples undergo chemical changes at room temperature. Blood cells begin to dissolve and the urine loses its acidity.

VISUAL EXAMINATION. A doctor, nurse, or laboratory technician will look at the specimen to see if the urine is red, cloudy, or looks unusual in any way. He or she will also note any unusual odor.

TESTING TECHNIQUES. Urine samples are tested with a variety of different instruments and techniques. Some tests use dipsticks, which are thin strips of plastic that change color in the presence of specific substances. Dipsticks can be used to measure the acidity of the urine (its pH) or the presence of blood, protein, sugar, or substances produced during the breakdown of fatty acids (ketones). A urinometer is used to compare the density of the urine specimen with the density of plain water. This measurement is called specific gravity.

The urine specimen is also examined under a microscope to determine whether it contains blood cells, crystals, or small pieces of fibrous material (casts).

Preparation

Voided specimens

Most urine specimens from adults or older children are collected by the patient's voiding into a suitable container. Soaps and disinfectants may contaminate urine specimens and should not be used. The doctor or laboratory may supply a special antiseptic solution that won't irritate the skin. The method for collection varies somewhat according to age and sex.

WOMEN AND GIRLS. Before collecting a urine sample, a woman or girl should use a clean cotton ball moistened with lukewarm water to cleanse the external genital area. Gently separating the folded skin (labia) on either side of her vagina, she should move the cotton ball from the front of the area to the back. After repeating this process several times, using a fresh piece of cotton each time, she should dry the area with a clean towel.

To prevent menstrual blood, vaginal discharge, or germs from the external genitalia from contaminating the specimen, a woman or girl should release some urine before she begins to collect her sample. A urine specimen obtained this way is called a midstream clean catch.

MEN AND BOYS. A man or boy should use a piece of clean cotton, moistened with antiseptic, to cleanse the head of his penis and the passage through which urine leaves his body (the urethral meatus). He should draw back his foreskin if he has not been circumcised. He should move the cotton in a circular motion away from the urinary opening, using a fresh piece of cotton each time. After repeating this process several times, he should use a fresh piece of cotton to remove the antiseptic. After the area has been thoroughly cleansed, he should begin urinating and collect a small sample in a container without interrupting the stream of urine.

INFANTS. A parent, nurse, or doctor should cleanse the child's genitals and as much of the surrounding area as will fit into the sterile urine-collection bag provided by the hospital. When the area has been thoroughly cleansed, the bag should be attached to the child's genital area and left in place until the child has urinated. It is important to remember not to touch the inside of the bag and to remove it as soon as a specimen has been obtained.

Bladder catheterization

Bladder catheterization is a hospital procedure used to collect uncontaminated urine when the patient cannot void. A catheter is a thin flexible tube that the doctor inserts through the urethra into the bladder to allow urine to flow out. To minimize the risk of infecting the patient's bladder with bacteria, many doctors use a so-called Robinson catheter, which is a plain rubber or latex tube that is removed as soon as the specimen is collected.

Suprapubic bladder aspiration is a technique that is sometimes used to collect urine from infants younger than six months. The doctor withdraws urine from the

bladder into a syringe through a needle inserted through the skin over the bladder. This technique is used only when the child cannot void because of an abnormal urethra or if he or she has a urinary tract infection that has not responded to treatment.

Aftercare

The patient may return to normal activities after collecting the sample and may start taking medications that were discontinued before the test.

Risks

There are no risks associated with voided specimens. The risk of bladder infection from catheterization with a Robinson catheter is about 3%.

Normal results

Contents and appearance

Normal urine is a clear straw-colored liquid. It has a slight odor. It contains some crystals, a small number of cells from the tissues that line the bladder, and transparent (hyaline) casts. Normal urine does *not* contain sugars, yeast cells, protein, ketones, bacteria, or parasitic organisms.

The time of day a urine sample is collected can make a difference in the appearance of the specimen. Some foods and medicines, including red beets, asparagus, and penicillin, can affect the color or smell of urine. Although most color variations are harmless, they sometimes indicate the presence of serious disease. A doctor, nurse, or laboratory technician should be notified if the urine is red or cloudy or looks unusual in any way.

Acidity

The pH of normal urine is 4.5–8.0. Its specific gravity is 1.0005–1.035.

Abnormal results

Cloudiness

Urine may be cloudy (turbid) because it contains red or white blood cells, bacteria, fat, mucus, digestive fluid (chyle), or pus from a bladder or kidney infection.

Odor

Foul-smelling urine is a common symptom of urinary tract infection. A fruity odor is associated with **diabetes mellitus**, **starvation**, **dehydration**, or ketone formation. Other distinctive odors are present in the urine of patients with maple syrup urine disease or **phenylketonuria** (PKU).

Specific gravity

The specific gravity of urine can be affected by a range of diseases and disorders. Low specific gravity (below 1.005) is associated with **diabetes insipidus**, nephrogenic diabetes insipidus, acute tubular necrosis, and inflammation of the upper urinary tract (**pyelonephritis**). In fixed specific gravity, the specific gravity of the urine remains at 1.010 no matter how much fluid the person drinks. This condition occurs in patients who have chronic inflammation of the small blood vessels in the kidneys (**glomerulonephritis**) and serious kidney damage. High specific gravity (above 1.035) occurs in patients who are in **shock** or who suffer from **nephrotic syndrome**, dehydration, acute glomerulonephritis, congestive **heart failure**, or liver failure.

pH

A pH factor greater than 7 (more alkaline) may result from **Fanconi's syndrome**, urinary tract infections, or metabolic or **respiratory alkalosis**. A pH factor below 7 (more acid) may be due to **fever**, PKU, the secretion of homogentisic acid in the urine (alkaptonuria), or acidosis.

Blood and tissue cells

Red blood cells in the urine can be due to vigorous **exercise** or exposure to toxic chemicals. Bloody urine can also be a sign of bleeding in the genitourinary tract as a result of systemic bleeding disorders, various kidney diseases, bacterial infections, parasitic infections including **malaria**, obstructions in the urinary tract, **scurvy**, subacute bacterial **endocarditis**, traumatic injuries, and tumors.

A high number of white blood cells in the urine is usually a symptom of urinary tract infection. A large number of cells from tissue lining (epithelial cells) can indicate damage to the small tubes that carry material into and out of the kidneys.

Casts

Casts are small fibrous objects that are formed when protein and other materials settle in the kidney tubules and collecting ducts. Casts are dislodged by normal urine flow. A large number of them in a urine specimen is a sign of **kidney disease**.

KEY TERMS

Acidosis—A condition of the blood in which bicarbonate levels are below normal.

Alkalosis—A condition of the blood and other body fluids in which bicarbonate levels are higher than normal.

Casts—Small fibrous objects formed from materials that collect in the kidney tubules and are washed out by normal urine flow.

Catheter—A thin flexible tube inserted through the urethra into the bladder to allow urine to flow out.

Clean catch specimen—A urine specimen that is collected from the middle of the urine stream after the first part of the flow has been voided.

Colony count—A measurement of the growth of bacteria in a urine sample that has been cultured for 24 to 48 hours.

Fanconi's syndrome—A rare disorder caused by vitamin D deficiency or exposure to heavy metals.

Ketones—Substances produced during the breakdown of fatty acids. They are produced in excessive amounts in diabetes and certain other abnormal conditions.

Nephrotic syndrome—A condition characterized by water retention, little or no protein in urine, and high blood cholesterol.

pH—A chemical symbol used to describe the acidity or alkalinity of a fluid, ranging from 0 (more acid) to 14 (more alkaline).

Urethra—The duct that carries urine from the bladder to the outside of the body.

Urinalysis (plural, urinalyses)—The diagnostic testing of a urine sample.

Voiding—Another word for emptying the bladder or urinating.

Crystals

There are several different chemicals in body fluids that can form crystals that appear in urine. Some of these appear in normal urine, such as **calcium** oxalate or uric acid crystals. A large number of calcium oxalate crystals, however, may be a sign of abnormally high levels of calcium in the blood (**hypercalcemia**). Other crystals, including tyrosine, leucine, and cholesterol, are abnormal. The presence of cystine crystals is a symptom of excessive urinary secretion of cystine (**cystinuria**). Cystine is an acid found in many proteins and normally reabsorbed by the kidney tubules.

Protein

Protein in the urine can be a symptom of **kidney stones**, inflammation of the kidneys, degenerative kidney disease, or multiple tumors.

Sugars

A high level of glucose and other sugars in the urine (glycosuria) is often a symptom of diabetes mellitus. Glycosuria can also be caused by advanced kidney disease, **Cushing's syndrome**, impaired tubular reabsorption, shock, a rare tumor of the adrenal gland (**pheochromocytoma**), or **cancer** of the pancreas.

Milk in the urine is normal if a woman is pregnant, has just given birth, or is **breastfeeding**. On the other hand, rare hereditary metabolic disorders are indicated when urine contains fruit sugar (fructose), milk sugar (galactose), or a simple sugar called pentose.

Ketones

The presence of abnormally high numbers of ketones in the urine (ketonuria) usually results from uncontrolled diabetes mellitus. Ketonuria can also be caused by prolonged **diarrhea** or **vomiting** that results in starvation.

Bilirubin

Bilirubin is an orange-yellow pigment found in bile, a fluid secreted by the liver. When it is found in urine, bilirubin may be a symptom of **liver disease** caused by the formation of fibrous tissue, medications that damage the liver, or obstructive **jaundice**.

Urobilinogen

Bacteria in the small intestine can convert bilirubin to urobilinogen, which is excreted in the feces, in bile, or in urine. An accumulation of urobilinogen in the urine may be a sign of severe infection, liver damage, or diseases that destroy red blood cells. Low levels of urobilinogen in the urine may be a result of antimicrobial therapy, inflammatory diseases, kidney disease, severe diarrhea, or blocked bile ducts.

Other findings

The presence of bacteria, parasites, or yeast cells in the urine may be a symptom of urinary tract infection or contamination of the external genitalia. Other factors that may affect urinalysis results include failure to collect a specimen during the day's first voiding, frequent urination, large dietary intake of vitamin C, and urine with a pH value lower than 6.

Urinary anti-infectives

Definition

Urinary anti-infectives are medicines used to treat or prevent infections of the urinary tract—the passage through which urine flows from the kidneys out of the body.

Purpose

Normally, no bacteria or other disease-causing organisms live in the bladder. Likewise, the urethra—the tube-like structure that carries urine from the bladder out of the body—usually has either no bacteria or not enough to cause problems. But the bladder, urethra, and other parts of the urinary tract may become infected when disease-causing organisms invade from other body regions or from outside the body. Urinary anti-infectives are used to treat such infections or to prevent them in people who get them often.

Description

Commonly used urinary anti-infectives include methenamine (Urex, Hiprex, Mandelamine), nalidixic acid (NegGram) and nitrofurantoin (Macrobid, Furatoin, and other brands). These medicines are available only with a physician's prescription and come in capsule, tablet, granule, and liquid forms.

Recommended dosage

Methenamine

For adults and children 12 years and over, the usual dosage is 1 gram, taken either twice a day or four times a day, depending on the form in which the drug comes. For children aged 6–12 years, the dosage ranges from 500 mg taken 2–4 times a day to 1 gram taken twice a day, again depending on the form of the drug. For children under 6 years, a physician must determine the dose.

This medicine will not work properly unless the urine is acidic, with a pH of 5.5 or below. The physician who prescribes the medicine will explain how to test the urine's acidity. The physician also may suggest diet changes that will make the urine more acidic, such as eating more protein, drinking cranberry juice, eating plums and prunes, but avoiding most other fruits, and cutting down on milk and other dairy products. **Antacids** should be avoided.

Nalidixic acid

The recommended dosage for adults and children 12 years and older is 1 gram every 6 hours. If the medicine is taken for more than one or two weeks, the dosage may be decreased to 500 mg every 6 hours. A physician must determine the correct dosage for children 3 months to 12 years old. Children under 3 months should not take this medicine because it causes bone problems in young animals and could have the same effect in young children.

Nitrofurantoin

CAPSULES, TABLETS, OR LIQUID. The usual dose for adults and teenagers is 50–100 mg every six hours.

EXTENDED-RELEASE CAPSULES. For adults and children 12 years and older, the usual dosage is 100 mg every 12 hours for seven days.

For all forms of nitrofurantoin, a physician must determine the correct dose for children one month and older, based on the child's body weight. Children under one month should not take this medicine.

Precautions

Methenamine

People with certain medical conditions may have additional problems with this medicine: it may worsen liver or **kidney disease**.

Nalidixic acid

This drug may produce **dizziness**, drowsiness or blurred vision. People should avoid driving or operating machinery until they have become accustomed to the effects of the drug.

Nalidixic acid may increase sensitivity to sunlight and **tanning** lights; even brief exposure may produce rash or **sunburn**. Even brief exposure to sun can cause a severe sunburn or a rash.

This drug may distort results from urine tests for sugar.

Laboratory studies have shown that nalidixic acid interferes with bone development in young animals and not recommended for use during **pregnancy**.

This medicine generally does not cause problems in nursing babies whose mothers take it. However, nursing babies with glucose-6-phosphate dehydrogenase (G6PD) deficiency (an inherited disorder that affects mainly black males) may have blood problems if their mothers take nalidixic acid.

People with a history of seizures or severe hardening of the arteries in the brain may be more likely to have side effects that affect the nervous system. People with glucose-6-phosphate dehydrogenase (G6PD) deficiency are more likely to have side effects that affect the blood. Also, people with **liver disease** or severe kidney disease have an increased chance of having any of the drug's possible side effects.

Nitrofurantoin

Pregnant women should not take this medicine within two weeks of their delivery date and should not use it during labor and delivery, as this could cause problems in the baby.

Women who are **breastfeeding** should check with their physicians before using this medicine. It passes into breast milk and could cause problems in nursing babies whose mothers take it. This is especially true of babies with glucose-6-phosphate dehydrogenase (G6PD) deficiency. The medicine also should not be given directly to babies up to one month of age, as they are particularly sensitive to its effects.

Older people may be more likely to have side effects when taking nitrofurantoin, because they are more sensitive to the drug's effects.

Taking nitrofurantoin may cause problems for people with certain medical conditions. Side effects may be greater, for example, in people with lung disease or nerve damage. In people with kidney disease, the medicine may not work as well as it should, but may cause more side effects. Those with glucose-6-phosphate dehydrogenase (G6PD) deficiency who take nitrofurantoin may develop anemia.

Diabetic patients should be aware that this medicine may cause false results on some urine sugar tests. They should check with a physician before making any changes in diet or diabetes medicine based on the results of a urine test.

General precautions for all urinary anti-infectives

Symptoms should improve within a few days of starting to take a urinary anti-infective. If they do not, or if they become worse, check with a physician. Patients who need to take this medicine for long periods should see their physicians regularly, so that the physician can check their progress.

Anyone who has had unusual reactions to urinary anti-infectives in the past should let his or her physician know before taking the drugs again. The physician should also be told about any **allergies** to foods, dyes, preservatives, or other substances. Patients taking nalidixic acid should tell their physicians if they have ever had reactions to medicines such as cinoxacin (Cinobac), ciprofloxacin (Cipro), enoxacin (Penetrex), norfloxacin (Noroxin), or ofloxacin (Floxin), all of which are also used to treat or prevent infections. Anyone taking nitrofurantoin should let the physician know if he or she has had an unusual reaction to medicines such as furazolidone (Furoxone) or nitrofurazone (Furacin).

Side effects

Methenamine

Nausea and vomiting are not common but may occur. These side effects do not need medical attention unless they are severe. One side effect that should be brought to a physician's attention immediately is a skin rash.

Nalidixic acid

Some side effects are fairly minor and are likely to go away as the body adjusts to the drug. These include dizziness, drowsiness, **headache**, **nausea** or **vomiting**, stomach **pain,** and **diarrhea**. Unless these problems continue or are bothersome, they do not need medical attention.

Other side effects, however, should have prompt medical attention. Anyone who has changes in vision, such as blurred vision, double vision, decreased vision, changes in color vision, halos around lights, or notices

KEY TERMS

Altitude sickness—A set of symptoms that people who normally live at low altitudes may have when they travel to high altitudes. The symptoms include nosebleed, nausea, and shortness of breath.

Anemia—A lack of hemoglobin–the compound in blood that carries oxygen from the lungs throughout the body and brings waste carbon dioxide from the cells to the lungs, where it is released.

Bacteria—Tiny, one-celled forms of life that cause many diseases and infections.

Glaucoma—A condition in which pressure in the eye is abnormally high. If not treated, glaucoma may lead to blindness.

Glucose-6-phosphate dehydrogenase (G6PD) deficiency—An inherited disorder in which the body lacks an enzyme that normally protects red blood cells from toxic chemicals. When people with this condition take certain drugs, their red blood cells break down, causing anemia. This may also happen when they have a fever or an infection. The condition usually occurs in males. About 10% of black males have it, as do a small percentage of people from the Mediterranean region.

Granule—A small grain or pellet. Medicines that come in granule form usually are mixed with liquids or sprinkled on food before they are taken.

Organism—An individual of some type of life form, such as a plant or an animal.

pH—A measure of how acidic or alkaline something is. The pH scale ranges from 0 to 14. Values below 7 are acidic; values above 7 are alkaline.

Seizure—A sudden attack, spasm, or convulsion.

an excessive brightness of lights should check with a physician immediately.

Nitrofurantoin

This medicine may make the urine turn reddish-yellow to brown. This is nothing to worry about. Other possible side effects that do not need medical attention unless they are severe include pain in the stomach or abdomen, stomach upset, diarrhea, loss of appetite, and nausea or **vomiting**.

Anyone who has chest pain, breathing problems, **fever**, chills, or a **cough** while taking nitrofurantoin should check with a physician immediately.

General advice on side effects for all urinary anti-infectives

Other side effects are possible when taking any urinary anti-infective. Anyone who has unusual symptoms while taking this type of medicine should get in touch with his or her physician.

Interactions

Methenamine

Certain medicines may make methenamine less effective. These include thiazide **diuretics** (water pills) and medicines that make the urine less acid, such as antacids, bicarbonate of soda, and the drugs acetazolamide (Diamox), dichlorphenamide (Daranide), and methazolamide (Neptazane), which are used to treat glaucoma, **epilepsy**, **altitude sickness**, and other conditions.

Nalidixic acid

People who are taking blood thinners (anticoagulants) may be more likely to have bleeding problems if they take this medicine.

Nitrofurantoin

Nitrofurantoin may interact with many other medicines. For example, taking nitrofurantoin with certain drugs that include methyldopa (Aldomet), **sulfonamides** (sulfa drugs), vitamin K, and diabetes medicines taken by mouth may increase the chance of side effects that affect the blood. General side effects are more likely in people who take nitrofurantoin with the **gout drugs** probenecid (Benemid) or sulfinpyrazone (Anturane). The risk of side effects that involve the nervous system is higher in people who take nitrofurantoin with various drugs including lithium (Lithane), disulfiram (Antabuse), other anti-infectives, and the **cancer** drugs cisplatin (Platinol) and vincristine (Oncovin). Patients who have had a DPT (**diphtheria**, **tetanus**, and pertussis) vaccine within the last 30 days or who have one after taking nitrofurantoin are also more likely to have side effects that affect the nervous system. Because of the many possible interactions, anyone taking nitrofurantoin should be sure to check with a physician before combining it with any other medicine.

General advice about interactions

Not every drug that may interact with a urinary anti-infective is listed here. Be sure to check with a physician or pharmacist before combining a urinary anti-infective with any other prescription or nonprescription (over-the-counter) medicine.

Urinary antiseptics *see* **Urinary anti-infectives**

Urinary catheterization

Definition

Urinary catheterization is the insertion of a catheter into a patient's bladder. The catheter is used as a conduit to drain urine from the bladder into an attached bag or container.

Purpose

Urinary catheterization is employed in hospital and nursing home settings to maintain urine output in patients who are undergoing surgery or who are confined to the bed and physically unable to use a bedpan. Critically ill patients who require strict monitoring of urinary output are also frequently catheterized.

Intermittent insertion of a urinary catheter is a treatment option for patients with certain types of **urinary incontinence**. Patients who are unable to completely empty the bladder during urination (urinary retention) or patients who have a bladder obstruction may also require intermittent urinary catheterization. Disabled individuals with neurological disorders that cause **paralysis** or a loss of sensation in the perineal area may also use regular intermittent catheter insertion to void their bladders.

Precautions

Because urinary catheterization carries a risk of causing **urinary tract infection** (UTI), precautions should be used to keep the catheter clean and free of bacteria. Patients requiring intermittent catheterization should be well trained in the technique by a qualified health care professional.

Description

Intermittent catheterization is performed a minimum of four times a day by the patient or a care giver. The genital area near the urethral opening is wiped with an antiseptic agent, such as iodine. A lubricant may be used to facilitate the entry of the catheter into the urethra, and a topical local anesthetic may be applied to numb the urethral opening during the procedure. One end of the catheter is placed in a container, and the other end is inserted into and guided up the urethra until urine flow begins. When urine flow stops, the catheter may be moved or rotated, or the patient may change positions to ensure that all urine has emptied from the bladder. The catheter is then withdrawn, cleaned, and sterilized for the next use. Recommended cleaning practices vary, from the use of soap and water to submersion in boiling water or a disinfectant solution. Some patients prefer to use a new catheter with each insertion.

Nonintermittent catheterization, which is initiated in a hospital or nursing home setting, uses the same basic technique for insertion of the urinary tract catheter. The catheter is inserted by a nurse or other health care professional and remains in the patient until bladder function can be maintained independently. When the catheter is removed, patients will experience a pulling sensation and may feel some minor discomfort. If the catheter is required for an extended period of time, a long-term, indwelling catheter, such as a Foley catheter, is used. To prevent infection, it should be regularly exchanged for a new catheter every three to six weeks.

Use of indwelling catheters should be restricted to patients whose incontinence is caused by urinary tract obstruction that can not be treated and for which alternative therapy is not feasible.

Preparation

If a patient wishes to perform intermittent catheterization himself, training in the technique by a qualified health care professional is required. Basic instruction in the anatomy, antiseptic techniques, catheter insertion, and proper catheter care should be provided. Patients learning chronic intermittent urinary catheterization may also benefit from an ultrasound examination to verify that they are completely emptying their bladder during the procedure.

Aftercare

Patients using intermittent catheterization as a treatment for incontinence will experience a period of

KEY TERMS

Bladder obstruction—A blockage of the bladder caused by the presence of calculi (e.g., mineral deposits) or an anatomic abnormality.

Catheter—A long, thin, flexible tube.

Foley catheter—A two-channel catheter with a balloon on the bladder end of one channel. Once inflated, the balloon keeps the catheter securely in the bladder. The other channel of the catheter facilitates the flow of urine out of the bladder.

Local anesthetic—Medication applied topically to the skin or administered through an injection that deadens a specific part of the body and inhibits the sensation of pain.

Perineal area—The genital area between the vulva and anus in a woman and between the scrotum and anus in a man.

Ultrasound examination—A diagnostic test that uses sound waves to generate a picture of an organ or organ system.

Urinary incontinence—The inability to control one's urine flow.

adjustment as they try to establish a catheterization schedule that is adequate for their normal level of fluid intake.

Antibiotics may be prescribed as a preventive measure in long-term urinary catheterization patients who are at risk for urinary tract infection.

A patient with an indwelling catheter must be reassessed periodically to determine whether alternative treatment may be more effective in treating the problem.

Risks

Trauma to the urethra and/or bladder may result from incorrect insertion of the catheter. Repeated irritation to the urethra during catheter insertion may cause scarring and/or stricture, or narrowing, of the urethra. The catheter may introduce bacteria into the urethra and bladder, resulting in urinary tract infection. UTI can cause **fever** and inflammation of the bladder and urethra. Patients who practice intermittent catheterization can reduce their risks for UTI by using antiseptic techniques for insertion and catheter care.

Normal results

When used correctly, catheterization facilitates complete voiding of the bladder.

Urinary diversion surgery

Definition

A urinary diversion involves removal of the urinary bladder and adjacent tissues and organs and re-routing of the urinary stream. This may involve creation of an artificial opening in the abdomen called an **ostomy**.

Purpose

A urinary diversion is created as a means to treat **cancer** of the bladder, when conservative measures have been unsuccessful, or when there is recurrence of the disease invading the muscle wall. Congenital deformities or traumatic injury may also necessitate formation of a urinary diversion.

Description

Under **general anesthesia**, an incision is made in the abdomen. The ureters (tubes that carry urine away from the kidneys) are cut and tied. The bladder and surrounding tissues are cut free and removed. The ureters are then attached to a portion of the intestine. The most common types of urinary diversion are:

- Ileal conduit. Ureters are attached to a portion of the small intestine, the ileum, one end of which is brought through the abdominal wall as a conduit for the urine, creating a stoma
- Ureterosigmoidostomy. The ureters are attached to a portion of the large intestine, the sigmoid, which allows the urine to flow through the large intestine and out through the rectum
- Cutaneous ureterostomy. Bringing the detached ureters through the abdominal wall and attaching it to an opening in the skin

Following creation of an artificial opening to drain the urine, ureteral stents (tubes that go through the stoma and up into the ureters) are often inserted and left in place to allow urine to drain freely from the kidneys, without risk of blockage from swelling due to surgery. The muscles are replaced and sewn together. A transparent pouch is applied to the abdomen to collect urine and attached to a bedside drainage bag. The incision is closed with sutures or clips ("staples"), which are usually removed about a week after surgery.

An alternative to a conventional urinary diversion is the continent urinary diversion. In this surgical procedure, a "false bladder" is constructed within the abdomen, using several lengths of small or large intestine. The ureters are sewn to this new reservoir for urine and nipple valves which are created at two sites: the abdominal wall for continence, and where the ureters are implanted, to prevent reflux of urine back to the kidneys. The patient is then taught to catheterize the reservoir to drain urine at regular intervals during the day. Although a continent diversion is not suitable for every patient who requires urinary diversion, it is an option to be considered.

Preparation

As with any surgical procedure, the patient will be required to sign a consent form after the procedure is explained thoroughly. Blood and urine studies, along with various x rays and an electrocardiogram (EKG), may be ordered as the doctor deems necessary. If creation of an ostomy is planned, the patient should visit an enterostomal therapist, who will mark an appropriate place on the abdomen for a stoma and offer preoperative education on ostomy management.

Eating or drinking is prohibited after midnight the night before the surgery. Oral anti-infectives, such as neomycin, erythromycin, or kanamycin sulfate, may be ordered to decrease bacteria in the intestine and help prevent postoperative infection. A nasogastric tube is inserted the day of surgery, or during surgery, to remove gastric secretions and prevent **nausea and vomiting**.

Aftercare

Postoperative care for a patient with a urinary diversion, as with those who have had any major surgery, involves monitoring of blood pressure, pulse, respirations, and temperature. Breathing tends to be shallow because of the effect of anesthesia, and the patient is reluctant to breathe deeply and experience **pain** that is caused by the abdominal incision. The patient is shown how to support the operative site during deep breathing and coughing and is given pain medication as necessary. Fluid intake and output are measured, and the operative site is observed for color and amount of wound drainage. The nasogastric tube will remain in place, attached to low intermittent suction, until bowel activity resumes. Fluids and electrolytes are infused intravenously until the patient's diet can gradually be resumed, beginning with liquids. The patient is usually able to move about in 8–24 hours after surgery and is discharged from the hospital in 5–10 days.

KEY TERMS

Ischemia— A compromise in blood supply to body tissues that causes tissue damage or death.

Ostomy—A surgically-created opening in the abdomen for elimination of waste products (urine or stool).

If an ostomy has been placed, the patient and close family members will be educated on how to care for it. Determination of appropriate pouching supplies and a schedule of how often to change the pouch should be established. Regular assessment and meticulous care of the skin surrounding the stoma is important to maintain an adequate surface on which to apply the pouch. The pouch should be connected to a bedside drainage bag at night to prevent large volumes of urine from collecting in the pouch. Otherwise, the weight of the pouch could cause disruption of the pouch seal and leakage of urine onto the surrounding skin. Often, an enterostomal therapist will visit the patient at home after discharge to help the new ostomy patient make the transition back to normal daily activities.

Risks

Potential complications of urinary diversion surgery include:

- excessive bleeding
- surgical wound infection
- thrombophlebitis (inflammation and blood clot to veins in the legs)
- pneumonia
- pulmonary embolism (blood clot or air bubble in the lungs' blood supply)

Normal results

Complete healing is expected without complications. The amount of time required for recovery from the surgery may vary depending of the patient's

overall health status prior to surgery. The patient with a urinary diversion, without other medical complications, should be able to resume all daily activities once recovered from the surgery.

Abnormal results

The doctor should be made aware of any of the following problems after surgery:

- increased pain, swelling, redness, drainage, or bleeding in the surgical area
- headache, muscle aches, dizziness, or fever
- increased abdominal pain or swelling, constipation, nausea, or vomiting

Stomal complications to be monitored include:

- Stomal tissue death (necrosis). This occurs because of inadequate blood supply, which is usually visible 12 to 24 hours after surgery and may require additional surgery
- Stoma flush or below the abdomen surface (retraction). Caused by insufficient stomal length, this may be managed by use of special pouching supplies. Elective revision of the stoma is also an option
- Narrowing at the opening of the stoma (stenosis). Often associated with infection around the stoma or scarring, mild stenosis can be removed under local anesthesia. Severe stenosis may require surgery for stomal revision
- Parastomal hernia. The bowel causes a bulge in the abdominal wall next to the stoma. This is usually due to placement of the stoma where the abdominal wall is weak or an overly large opening in the abdominal wall. Use of an ostomy support belt and special pouching supplies may be adequate. If severe, the defect in the abdominal wall should be repaired and the stoma moved to another location

ORGANIZATIONS

Kathleen D. Wright, RN

Urinary incontinence

Definition

Urinary incontinence is unintentional loss of urine that is sufficient enough in frequency and amount to cause physical and/or emotional distress in the person experiencing it.

Description

Approximately 13 million Americans suffer from urinary incontinence. Women are affected by the disorder more frequently than men; one in 10 women under age 65 suffers from urinary incontinence. A study published in late 2002 found that between 21% and 29% of adult women in the workforce reported at least one episode of urinary incontinence each month. Older Americans, too, are more prone to the condition. Twenty percent of Americans over age 65 are incontinent. In general, the condition is underrecognized and undertreated.

There are five major categories of urinary incontinence: overflow, stress, urge, functional, and reflex.

- Overflow incontinence. Overflow incontinence is caused by bladder dysfunction. Individuals with this type of incontinence have an obstruction to the bladder or urethra, or a bladder that doesn't contract properly. As a result, their bladders do not empty completely, and they have problems with frequent urine leakage.
- Stress incontinence. Stress incontinence occurs when an individual involuntarily loses urine after pressure is placed on the abdomen (i.e., during exercise, sexual activity, sneezing, coughing, laughing, or hugging).
- Urge incontinence. Urge incontinence occurs when an individual feels a sudden need to urinate, and cannot control the urge to do so. As a consequence, urine is involuntarily lost before the individual can get to the toilet.
- Functional incontinence. Individuals who have control over their own urination and have a fully functioning urinary tract, but cannot make it to the bathroom in time due to a physical or cognitive disability, are functionally incontinent. These individuals may suffer from arthritis, Parkinson's disease, multiple sclerosis, or Alzheimer's disease.
- Reflex incontinence. Individuals with reflex incontinence lose control of their bladder without warning. They typically suffer from neurological impairment.

In some cases, an individual may develop short-term or *acute incontinence*. Acute incontinence may occur as a symptom or by-product of illness, as a side effect of medication, or as a result of dietary intake. The condition is typically easily resolved once the cause is determined and addressed.

Causes and symptoms

Urinary incontinence can be caused by a wide variety of physical conditions, including:

- Childbirth. Childbirth can weaken the pelvic muscles and cause the bladder to lose some support from surrounding muscles, resulting in stress incontinence.
- Dysfunction of the bladder and/or the urinary sphincter. In a continent individual, as the bladder contracts, the outlet that releases urine into the urethra (bladder sphincter) opens and urine exits the body. In individuals with overflow incontinence, bladder contractions and dilation of the sphincter do not occur at the same time.
- Enlarged prostate. In men, an enlarged prostate gland can obstruct the bladder, causing overflow incontinence.
- Hysterectomy or other gynecological surgery. Any surgery involving the urogenital tract runs the risk of damaging or weakening the pelvic muscles and causing incontinence.
- Menopause. The absence of estrogen in the postmenopausal woman can cause the bladder to drop, or prolapse.
- Neurological conditions. The nervous system sends signals to the bladder telling it when to start and stop emptying. When the nervous system is impaired, incontinence may result. Neurological conditions such as multiple sclerosis, stroke, spinal cord injuries, or a brain tumor may cause the bladder to contract involuntarily, expelling urine without warning or to cease contractions completely, causing urinary retention.
- Obesity. Individuals who are overweight have undue pressure placed on their bladder and surrounding muscles.
- Obstruction. A blockage at the bladder outlet may permit only small amounts of urine to pass, resulting in urine retention and subsequent overflow incontinence. Tumors, calculi, and scar tissue can all block the flow of urine. A urethral stricture, or narrow urethra caused by scarring or inflammation, may also result in urine retention.

Acute incontinence is a temporary condition caused by a number of factors, including:

- Bladder irritants. Substances in the urine that irritate the bladder may cause the bladder muscle to malfunction. The presence of a urinary tract infection and the ingestion of excess caffeine can act as irritants. Highly concentrated urine resulting from low fluid intake may also irritate the bladder.
- Constipation. Constipation can cause incontinence in some individuals. Stool that isn't passed presses against the bladder and urethra, triggering urine leakage.
- Illness or disease. Diabetes can greatly increase urine volume, making some individuals prone to incontinence. Other illnesses may temporarily impair the ability to recognize and control the urge to urinate or to reach the toilet in time to do so.
- Medications and alcohol. Medications that sedate, such as tranquilizers and sleeping pills, can interfere with the proper functioning of the urethral nerves and bladder. Both sedatives and alcohol can also impair an individual's ability to recognize the need to urinate and act on that need in a timely manner. Other medications, such as diuretics, muscle relaxants, and blood pressure medication, can also affect bladder function.
- Surgery. Men who undergo prostate surgery can suffer from temporary stress incontinence as a result of damage to the urethral outlet.

Diagnosis

Urinary incontinence may be diagnosed by a general practitioner, urologist, or gynecologist. If the patient is over age 65, a geriatrician may diagnose and treat the condition. A thorough medical history and **physical examination** is typically performed, along with specific diagnostic testing to determine the cause of the incontinence. Diagnostic testing may include x rays, ultrasound, urine tests, and a physical examination of the pelvis. It may also include a series of exams that measure bladder pressure and capacity and the urinary flow (urodynamic testing). The patient may also be asked to keep a diary to record urine output, frequency, and any episodes of incontinence over a period of several days or a week.

Treatment

There are numerous invasive and noninvasive treatment options for urinary incontinence:

- Behavior modification therapy. Behavior modification is a psychological approach to the treatment of urinary incontinence in which patients gradually increase the length of the time interval between voidings and "retrain" the bladder in other ways. It is reported to be highly effective in treating urge incontinence.
- Biofeedback. The use of sensors to monitor temperature and muscle contractions in the vagina to help

KEY TERMS

Bladder neck—The place where the urethra and bladder join.

Bladder sphincter—The outlet that releases urine into the urethra.

Calculi (singular, calculus)—Mineral deposits that can form a blockage in the urinary system.

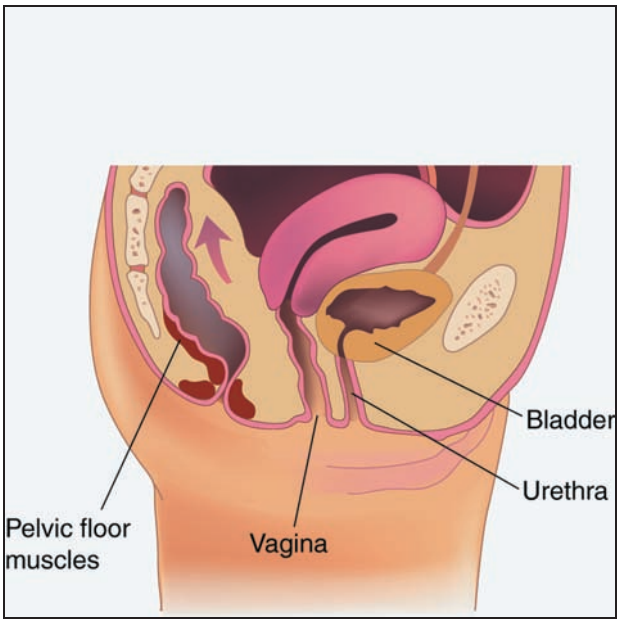
Occlusive—Closing off. One of the newest treatments for stress urinary incontinence in women is an external occlusive single-use cap that covers the urethral opening.

Perineal area—The genital area between the vulva and anus in a woman and between the scrotum and anus in a man.

Sacral nerves—The five pairs of nerves that arise from the lowermost segments of the spinal cord and control bladder, bowel, and pelvic functions. Stimulation of the sacral nerves by an implanted device is a newer treatment for urinary incontinence.

incontinent patients learn to control their pelvic muscles.

- Collagen injections. Collagen injected in the tissue surrounding the urethra can provide urethral support for women suffering from stress incontinence.
- External occlusive devices. A new single-use disposable urethral cap is available without a prescription as of late 2002 for women suffering from stress urinary incontinence. The cap is noninvasive and appears to be quite effective in managing incontinence.
- Inflatable urethral insert. Sold under the trade name Reliance, this disposable incontinence balloon for women is inserted into the urethra and inflated to prevent urine leakage.
- Intermittent urinary catheterization. The periodic insertion of a catheter into a patient's bladder to drain urine from the bladder into an attached bag or container.
- Medication. Estrogen hormone replacement therapy can help improve pelvic muscle tone in postmenopausal women. Other medications, including flurbiprofen, capsaicin, and botulinum toxin, are sometimes prescribed to relax the bladder muscles or to tighten the urethral sphincter. As of late 2002, newer medications for the treatment of urinary incontinence were undergoing clinical trials. One of these drugs, duloxetine, differs from present medications in targeting the central nervous system's control of the urge to urinate rather than the smooth muscle of the bladder itself.
- Pelvic toning exercises. Exercises to tone the pelvic muscle can help alleviate stress incontinence in both men and women. These exercises involve tightening the muscles of the pelvic floor and are also known as Kegel or PC muscle exercises.
- Perineal stimulation. Perineal stimulation is used to treat stress incontinence. The treatment uses a probe to deliver a painless electrical current to the perineal area muscles. The current tones the muscle by contracting it.
- Permanent catheterization. A permanent, or indwelling, catheter may be prescribed for chronic incontinence that doesn't respond to other treatments. A Foley catheter is usually used for urinary catheterization. One end is inserted through the urethra and into the bladder, and the external end is attached to a plastic reservoir bag that the patient may wear on the leg. A second alternative is a permanent catheter, called a suprapubic tube, surgically inserted into the bladder. The tube exits the body through the abdomen near the pubic bone, where it is attached to a drainage bag. As infection may result, this treatment should be reevaluated periodically, and the possibility of alternative treatment addressed.
- Sacral nerve stimulation (SNS). Also known as sacral neuromodulation, SNS is a procedure in which a surgeon implants a device that sends continuous stimulation to the sacral nerves that control the urinary sphincter. The FDA approved sacral nerve stimulation for the treatment of urinary urge incontinence in 1997 and for urinary frequency in 1999.
- Surgery. Bladder neck suspension surgery is used to correct female urinary stress incontinence. Surgical techniques such as the Marshall-Marchetti-Krantz and Burch procedures use sutures to raise and support the bladder neck and urethra. A sling procedure, which uses a strip of biocompatible material or the patient's own muscle or tissue as a supportive sling under the urethra and bladder neck, may also be used to treat stress incontinence. Bladder enlargement surgery may be recommended to treat incontinent men and women with unusually small bladders.
- Urinary sphincter implant. An artificial urinary sphincter may be used to treat incontinence in men and women with urinary sphincter impairment.



Strengthening the pelvic floor muscles by performing Kegel exercises helps to alleviate stress incontinence in women. Contract the pelvic floor muscles as if stopping an imaginary flow of urine. Hold for 10 seconds and repeat. *(Illustration by Electronic Illustrators Group. Reproduced by permission of Gale, a part of Cengage Learning.)*

- Vaginal inserts. Devices constructed of silicone or other pliable materials that can be inserted into a woman's vagina to support the urethra.

Prognosis

Left untreated, incontinence can cause physical and emotional upheaval. Individuals with long-term incontinence suffer from urinary tract infections, and skin **rashes** and sores. Incontinence can also affect their self-esteem and cause depression and social withdrawal. They frequently stop participating in physical activities they once enjoyed because of the risk of embarrassing "accidents." However, with the wide variety of treatment options for incontinence available today, the prognosis for incontinent patients is promising. If incontinence cannot be stopped, it can be improved in the majority of cases.

Prevention

Women who are pregnant or who have gone through **childbirth** can reduce their risk for stress incontinence by strengthening their perineal area muscles with Kegel exercises. Men who have undergone prostate surgery may also benefit from pelvic muscle exercises. Men and women should consult with their doctor before initiating any type of **exercise** program.

Urinary tract infection

Definition

A urinary tract infection (UTI) is a bacterial infection in any part of the urinary tract—the urethra, bladder, ureters, or kidneys.

Demographics

UTIs are not uncommon in children. Approximately 1% of boys and 3% of girls develop a symptomatic UTI before the age of 11. During the first year of life, uncircumcised boys are two and half times as likely as girls to develop a UTI. However after the first year, girls are 20 times as likely as boys to develop UTIs. Girls are particularly susceptible to UTIs around the age of three as toilet training begins. The incidence of UTIs in both boys and girls decreases with age.

Description

The urinary tract produces and discharges urine from the body. It includes the kidneys, ureters, bladder, urethra, and, in males, the prostate. Urine, consisting of water and waste products, is produced by the kidneys and carried through the ureters to the bladder for storage. The urethra carries the urine from the bladder to the outside of the body. In males the urethra carries the urine through the prostate and out through the penis. The urethra in females is shorter and opens to the outside in front of the vaginal opening.

Urine is normally sterile, meaning that it is free from infectious organisms such as bacteria. The urinary tract has various mechanisms for protecting itself from infection:

- Urine has antibacterial properties.
- Urine is prevented from backing up in the ureters to the kidneys.
- The bladder secretes a protective coating that prevents bacteria from attaching to its lining.
- The flow of urine flushes bacteria from the body.

Infection can occur when bacteria attach to the opening of the urethra and enter the urinary tract. A UTI causes an inflammatory response in the lining of the urinary tract (the urothelium). Infections can affect the urethra (**urethritis**) and/or the bladder (**cystitis**). Untreated UTIs can reach the kidneys and cause a serious medical condition called **pyelonephritis**. However, in children most UTIs are restricted to the bladder.

Risk factors

A major risk factor for UTIs in girls is wiping from back to front (anus to urethral opening) after using the toilet. Other risk factors for UTIs in children include:

- previous UTIs
- infrequent or inadequate urination
- constipation in which a hard stool in the bowel presses against the urinary tract and impedes the flow of urine
- poor growth
- bubble baths
- tight–fitting clothing
- a family history of kidney disease
- birth defects in the urinary tract, especially vesicoureteral reflux—a defect in the valves between the ureters and the bladder that allows urine to back up into the ureters and kidneys
- a growth (mass) in the abdomen
- central nervous system disorders—such as myelomeningocele, spinal cord injury, or hydrocephalus—that make it difficult for children to completely empty their bladders

A susceptibility to UTIs often carries on into adulthood. In at least some cases, this susceptibility appears to be inherited.

Causes and symptoms

UTIs are caused by bacteria that enter the urinary tract. These bacteria are normally are found on the skin around the anus and sometimes around the vagina in girls or come from stool after a bowel movement. More than 95% of UTIs in children are caused by Enterobacteriaceae, a family of bacteria that includes ***Escherichia coli*** (*E. coli*), *Klebsiella* sp., *Proteus* sp., *Pseudomonas* sp., or *Enterococcus* sp.

Although some children are simply more susceptible to UTIs than others, the most common causes of bacteria entering a child's urinary tract are:

- girls wiping from back to front after using the toilet
- delayed urination
- failure to completely empty the bladder

KEY TERMS

Bacteriuria—The presence of bacteria in the urine.

Bladder—The elastic, muscular pouch in which urine collects before being discharged from the body through the urethra.

Catheter—A hollow, flexible tube that is inserted into a body cavity, duct, or vessel for the passage of fluids or to distend a passageway.

Cystitis—Inflammation of the bladder.

Inflammatory response—The immune system's response to tissue injury caused by a physical, chemical, or biological substance.

Kidneys—The pair of bean–shaped organs, located below the ribs toward the middle of the back, which cleanse the blood, regulate acid concentration, and maintain water balance in the body through the formation of urine.

Prostate—The walnut–shaped gland that surrounds the urethra at the neck of the bladder in males and supplies fluid for semen.

Pyelonephritis—Bacterial infection of the kidney.

Sterile—Free from infectious organisms such as bacteria.

Ureters—The tubes that drain urine from the kidneys to the bladder.

Urethra—The tube that discharges urine from the bladder to the outside of the body. In males the urethra is located in the penis. In females the urethra is shorter than in the males and emerges above the vaginal opening.

Urethritis—Infection of the urethra.

Urinary tract—The organs that produce and discharge urine, including the kidneys, ureters, bladder, and urethra.

Urine—The fluid containing water and waste products that is produced by the kidneys, stored in the bladder, and removed from the body through the urethra.

Urothelium—The lining of the urinary tract, including the renal pelvis, ureters, bladder, and urethra.

Although young children with UTIs often have no symptoms, when symptoms are present they may include:

- fever, especially a recurring fever with no apparent cause
- poor appetite or refusal to eat
- fussiness or irritability
- diarrhea
- vomiting
- cloudy or foul–smelling urine
- blood in the urine

Symptoms of UTIs in older children may include:

- pain or burning during urination
- frequent urination
- bedwetting or daytime wetting
- dark or cloudy urine
- blood in the urine
- stomach or back pain

Additional symptoms of a bladder infection in children include:

- strong–smelling urine
- frequent or urgent need to urinate
- a general feeling of illness (malaise)
- pain or pressure in the lower back or lower pelvis

UTIs that spread to the kidneys can cause pyelonephritis. Symptoms of pyelonephritis include:

- fever
- flushed, red, or warm skin
- pain in the lower back or side
- severe belly pain
- nausea and vomiting
- shaking chills

Diagnosis

Examination

Clinical signs and symptoms are usually suggestive of a UTI. The child will be checked for **fever** and the physician will examine the child's abdomen and lower back for masses, bladder swelling, and unusual enlargement of the kidneys.

Tests

UTIs are diagnosed by **urinalysis**. A urine sample is collected by having the child urinate into a cup. If a child is still using diapers, the area around the urethra is

cleansed with soap and warm water or a sterile wipe, and a collection bag is held in place over the urethral opening with adhesive strips. Sometimes urine is collected from infants and toddlers by inserting a catheter—a thin plastic tube—into the urethra to collect urine directly from the bladder. A suprapubic urine collection is performed by inserting a needle through the skin and muscles of the lower abdomen into the bladder.

The urine sample is examined under a microscope or tested with dipsticks for the presence of bacteria (bacteriuria), red blood cells, and white blood cells that indicate an immune system response to infection. The urine sample may be sent to a laboratory for culturing to determine the type of bacteria and the appropriate antibiotic for treatment. Additional blood tests may be performed to diagnose a kidney infection.

Procedures

Imaging procedures are sometimes performed to determine whether UTIs are caused by urinary reflux or another problem that is blocking urine flow. Imaging is also used to diagnose kidney damage. Although imaging may be performed while the child has a UTI, it is more often done after the infection has cleared up. Procedures include:

- ultrasound of the urinary tract
- a cystourethrogram—an x ray of the bladder and urethra, taken after injection of a contrast dye, to detect structural abnormalities
- a voiding cystourethrogram—an x ray taken while the child is urinating
- intravenous pyelogram for obtaining x-ray images of the bladder, kidneys, and ureters
- cystoscopy—in which a thin tube called a cystoscope, containing a light and a camera, is inserted through the urethra to examine the inside of the bladder and ureters and possibly remove a small amount of tissue for examination by a pathologist
- computed tomography (CT) scans to detect a kidney infection or cancer in the urinary tract

Treatment

Traditional

UTIs are treated immediately with **antibiotics** to protect the child's developing kidneys from infection. However urinary reflux or other structural problems may require surgery. Urinary reflux is sometimes treated by cutting one or both ureters away from the bladder and reattaching them at a different angle to prevent urine from backing up. Urinary reflux may also be treated by injecting a bulking agent around the ureter opening so that urine can flow into the bladder but is prevented from backing out.

Drugs

UTIs are usually treated immediately with oral antibiotics against the most common bacteria. Sometimes the type of antibiotic is changed after laboratory results have identified the specific bacterium. Most antibiotics are taken for 9 to 10 days, although some may require a two–week course of treatment. Young infants may require intravenous antibiotics that are administered in a hospital. Some children with recurrent UTIs are treated with antibiotics for as long as six months to two years. The most common antibiotics for treating UTIs in children include:

- amoxicillin (Amoxil, Trimox, Wymox) or amoxicillin/clavulanic acid (Augmentin)
- cephalosporins
- nitrofurantoin (Macrodantin, Furadantin)
- trimethoprim–sulfamethoxazole (TMP/SMZ; Bactrim, Septra, Cotrim)
- doxycycline, in children aged eight and older

Alternative

Although UTIs in children must be treated with antibiotics to prevent kidney damage, antimicrobial herbal therapies include:

- garlic (*Allium sativum*)
- goldenseal (*Hydrastis canadensis*)
- bearberry (*Arctostaphylos uva–ursi*)

Other alternative treatments for UTIs include:

- demulcents, such as corn silk and marsh mallow (*Althaea officinalis*), to soothe and coat the urinary tract
- homeopathic medicines based on the child's symptoms
- Chinese traditional medicine
- acupuncture

Alternative treatments should be used with care, as the benefits of many such treatments have not been confirmed by scientific research.

Home remedies

The most important home remedy for a UTI is drinking plenty of fluids, especially water. Other home treatments include:

- unsweetened cranberry juice, which has antibacterial activity
- ascorbic acid (vitamin C), which increases acidity of the urine

- eliminating all sugar from the diet
- avoiding soft drinks with caffeine, citrus juices, spicy foods, coffee, and alcohol
- applying a heating pad to the lower abdomen
- soaking the pelvis in warm or hot water (a sitz bath) for 15–20 minutes

Prognosis

UTIs in children are usually readily cured with antibiotics and have an excellent prognosis, although they may require long–term treatment with low–dose antibiotics. A new antibiotic–resistant strain of *E. coli* is increasingly difficult to treat. Almost 26% of infants with symptomatic UTIs have a recurrence, usually within three months. About 40–60% of older girls with a UTI will also have a recurrence. However most children outgrow urinary reflux problems.

Repeated UTIs in children can damage their kidneys. Scarring of the kidneys is the fourth–leading cause of **kidney transplantation** in children. Long–term complications of repeated UTIs may include:

- pyelonephritis
- an abscess in a kidney
- high blood pressure
- kidney swelling (hydronephrosis)
- kidney insufficiency or failure

Prevention

Although some highly susceptible children may require long–term preventive antibiotic treatment, most UTIs in children can be prevented by good toilet hygiene:

- urinating regularly, whenever the child feels the urge, and never holding in urine
- emptying the bladder completely
- wiping from front to back, away from the urethra, especially after a bowel movement
- keeping the genital area clean

Other practices for preventing UTIs in children include:

- drinking plenty of fluids, especially water
- avoiding tight–fitting clothes that trap moisture and encourage bacterial growth
- wearing only cotton underwear that allows air in to dry out the genital area
- avoiding bubble bath and any other irritating products in the genital area
- taking showers rather than baths
- monitoring urination patterns in young children
- having older children notify their parents if urination becomes painful
- treating constipation
- drinking cranberry juice or taking vitamin C

Urine concentration test *see* **Kidney function tests**

Urine culture

Definition

A urine culture is a diagnostic laboratory test performed to detect the presence of bacteria in the urine (bacteriuria).

Purpose

Culture of the urine is a method of diagnosis for **urinary tract infection** that determines the number of microorganisms present in a given quantity of urine.

Precautions

If delivery of the urine specimen to the laboratory within one hour of collection is not possible, it should be refrigerated. The health care provider should be informed of any **antibiotics** currently or recently taken.

Description

There are several different methods for collection of a urine sample. The most common is the midstream clean-catch technique. Hands should be washed before beginning. For females, the external genitalia (sex organs) are washed two or three times with a cleansing agent and rinsed with water. In males, the external head of the penis is similarly cleansed and rinsed. The patient is then instructed to begin to urinate, and the urine is collected midstream into a sterile container. In infants, a urinary collection bag (plastic bag with an adhesive seal on one end) is attached over the labia in girls or a boy's penis to collect the specimen.

Another method is the catheterized urine specimen in which a lubricated catheter (thin rubber tube) is inserted through the urethra (tube-like structure in which urine is expelled from the bladder) into the bladder. This avoids contamination from the urethra or external genitalia. If the patient already has a urinary catheter in place, a urine specimen may be collected by clamping the tubing below the collection port and using a sterile needle and syringe to obtain the urine sample; urine cannot be taken from the drainage bag, as it is not fresh and has had an opportunity to grow bacteria at room temperature. On rare occasions, the health care provider may collect a urine sample by inserting a needle directly into the bladder (suprapubic tap) and draining the urine; this method is used only when a sample is needed quickly.

KEY TERMS

Bacteriuria—The presence of bacteria in the urine.

Negative culture results showing no bacterial growth are available after 24 hours. Positive results require 24–72 hours to complete identification of the number and type of bacteria found.

Preparation

Drinking a glass of water 15–20 minutes before the test is helpful if there is no urge to urinate. There are no other special preparations or aftercare required for the test.

Risks

There are no risks associated with the culture test itself. If insertion of a urinary catheter (thin rubber tube) is required to obtain the urine, there is a slight risk of introducing infection from the catheter.

Normal results

No growth of bacteria is considered the normal result, and this indicates absence of infection.

Abnormal results

Abnormal results, or a positive test, where bacteria are found in the specimen, may indicate a urinary tract infection. Contamination of the specimen from hair, external genitalia, or the rectum may cause a false-positive result. Identification of the number and type of bacteria, with consideration of the method used in obtaining the specimen, is significant in diagnosis.

Escherichia coli causes approximately 80% of infections in patients without catheters, abnormalities of the urinary tract, or calculi (stones). Other bacteria that account for a smaller portion of uncomplicated infections include *Proteus klebsiella* and *Enterobacter*.

ORGANIZATIONS

Kathleen D. Wright, RN

Urine flow test

Definition

A urine flow test evaluates the speed of urination, or amount voided per second, and the total time of urination.

Purpose

A urine flow test is utilized to determine bladder function abnormalities, including a narrowed or obstructed urethra (the outflow passage from the bladder) and a weakened bladder muscle (detrusor).

Description

During a urine flow test, the patient urinates into a uroflowmeter, a funnel-shaped device that reads, measures, and computes the rate and amount of urine flow. The test takes approximately 10 minutes.

Preparation

The patient is prohibited from urinating at least two hours before the procedure.

Normal results

Average urine flow rates vary depending on age and gender.

Abnormal results

A urine flow test can indicate problems in bladder function, such as an obstruction, that will need further tests to diagnose.

Uterine fibroid embolization

Definition

Uterine fibroids are growths in the muscular tissue of the womb (uterus). Uterine fibroid embolization is non-surgical removal of the growths through the use of a tubular device called a catheter.

Purpose

It is estimated that between 20% and 40% of women over age 35 years have fibroids. These noncancerous tumors of the uterus, also called myomas, fibromyomas, or leiomyomas, can be as tiny as a pea or grow to as large as a cantaloupe. They grow along the muscular wall of the uterus and are made of both muscle and fiber-like tissue. Although they are not cancerous, they can cause uncomfortable symptoms in women, particularly **pain** and a feeling of pressure in the area between the hip bones (the lower pelvic area). Some women experience a feeling that they constantly need to urinate. Others may feel pressure in the bowel and experience bloating or **constipation**. Sometimes, fibroids cause heavy menstrual bleeding and lengthier menstrual periods.

In some cases, women need no treatment for fibroids, since the growths may cause no symptoms or may stop causing symptoms when a woman reaches **menopause**. However, when the fibroids cause heavy bleeding that can lead to anemia, pelvic pain, and create pressure on other organs, the physician and patient may discuss treatment options. A woman still planning to have children may need to have fibroids removed to ensure they do not interfere with the ability of a fertilized egg to implant on her uterine lining. In rare cases, fibroids cause such severe and sharp pelvic pain that emergency treatment is required.

Although some medications may help ease the symptoms of fibroids or even slow their growth, they are not long-term solutions to the fibroid growths. Surgery also can remove the fibroids. **Myomectomy** is the most common surgery option still used to treat fibroids because it does not involve removing the uterus. In severe cases, women may have a **hysterectomy** and have their uterus removed.

The development of uterine fibroid embolization has offered women a non-surgical alternative to treating fibroids that are causing symptoms. It also is effective for treating multiple fibroids.

Precautions

Although uterine fibroid embolization has been shown in many studies to be effective, some physicians say it is a relatively new procedure that lacks long-term data on its effectiveness. Estimates show that at least 90% of women who have the procedure will have relief of symptoms and no return of fibroids. Some women have reportedly stopped having menstrual periods following the procedure. Since the long-term effects of uterine fibroid embolization on future pregnancies has not been studied extensively, patients still wanting to have children should discuss the latest research and fibroid treatment options with their physicians. Overall, however, the treatment is a safer and less invasive alternative than surgery.

Description

Uterine fibroid embolization usually is performed in a hospital, but sometimes in an outpatient imaging center. An interventional radiologist normally performs the procedure. Interventional radiologists are physicians who are specially trained to use x rays to see inside the body while guiding narrow tubes called catheters through blood vessels to diagnose or treat various diseases.

Uterine fibroid embolization also may be called uterine artery embolization. This is because the procedure injects tiny particles, called embolic agents, into the artery that supplies blood to the fibroid tumor, blocking off the tumor's blood supply. The radiologist reaches the uterine artery by first making a small nick (about one-quarter of an inch) in the patient's skin in the groin area. From this incision, the radiologist can inset the catheter into the femoral artery and then guide the catheter toward the area of the uterus. Patients do not feel the catheter as it moves along the artery and a nurse or anesthesiologist will provide drugs for pain relief at the insertion site. The nurse or a technologist also will insert a Foley catheter into the patient's bladder. This keeps the bladder emptied so that the radiologist can have a better picture of the uterus and the anatomy that surrounds the uterus during the procedure.

The radiologist can view the progress of the catheter using a moving x-ray technique called fluoroscopy. When the catheter reaches the artery supplying blood to the fibroid tumor, the radiologist injects the embolic agents, which are only about the size of grains of sand. When they gather together, they form a clot, and since no more blood can reach the fibroids, they eventually will shrink and disappear. If a woman has fibroids on both sides, the radiologist will guide the catheter around to repeat the procedure on the other side of the uterus. After removing the catheter, the medical team will clean the puncture area and cover it with a bandage. They also remove the Foley catheter. The entire procedure takes about one hour and should cost less than hysterectomy or other surgical treatments. Most insurance companies will pay for uterine fibroid embolization.

Preparation

When the embolization is scheduled, the hospital or facility should provide instructions regarding medications or food and drink to avoid prior to the procedure. Once a patient checks in, a nurse or technician may draw blood for routine tests and a nurse or radiologic technologist who specializes in vascular procedures will start an intravenous (IV) line through which the patient will receive **antibiotics** to prevent infection.

Aftercare

Although uterine fibroid embolization is an outpatient procedure, patients may stay in a recovery area for up to 23 hours. When patients are discharged, they will receive specific instructions about follow-up care and medication for relief of pain and swelling. Uterine fibroid embolization rarely requires stitches. Patients may be advised to use a stool softener while taking some of the aftercare medications to avoid constipation. They will be instructed to drink plenty of fluids for the first week following the procedure. Normally, the patient should avoid soaking in hot baths for the first three days and should not drive a car for about three days following uterine fibroid embolization.

Strenuous activity, such as climbing stairs, squatting, or lifting heavy objects should be avoided for about one week. Patients also should not stand in one position for long periods of time in the first week following the procedure. It is usually best to avoid heavy **exercise** routines, athletic activity and sexual

KEY TERMS

Anemia—A condition in which the blood has a low number of red blood cells, low hemoglobin, or low total blood volume.

Artery—One of several tubular branches of muscular and elastic walled vessels that carry blood from the heart through the body.

Femoral artery—The chief artery of the thigh.

Groin—The fold that marks the meeting of the lower abdomen and the inner thigh.

relations for about up to month. Women also may be advised to avoid using tampons for menstrual periods for up to three months following uterine fibroid embolization, substituting sanitary pads.

Risks

Most patients experience moderate to severe pain and cramping for several hours after the procedure and some will have **nausea** and **fever**. There is a risk of infection from uterine fibroid embolization, but the risk is small and the infection usually can be controlled by antibiotics. A small percentage (about 1%) of women may experience an injury to the uterus or an infection that may lead to a later hysterectomy. There also is a small risk that a woman will stop having periods after uterine fibroid embolization. Overall, these risks are relatively low compared to surgical removal of fibroids.

Normal results

About 90% of women who have the procedure experience significant or complete relief of heavy bleeding, pain, and other symptoms. Patients usually will follow up with their gynecologist about two weeks following the procedure. Recurrence of fibroids is rare, though long-term studies of 10 years or more have shown that about 10% of patients may need additional treatment after 10 years. Additional studies continue on the procedure's long-term effectiveness.

Teresa G. Odle,

Uterine fibroids

Definition

Uterine fibroids (also called leiomyomas or myomas) are benign growths of muscle inside the uterus. They are not cancerous, nor are they related to **cancer**. Fibroids can cause a wide variety of symptoms, including heavy menstrual bleeding and pressure on the pelvis.

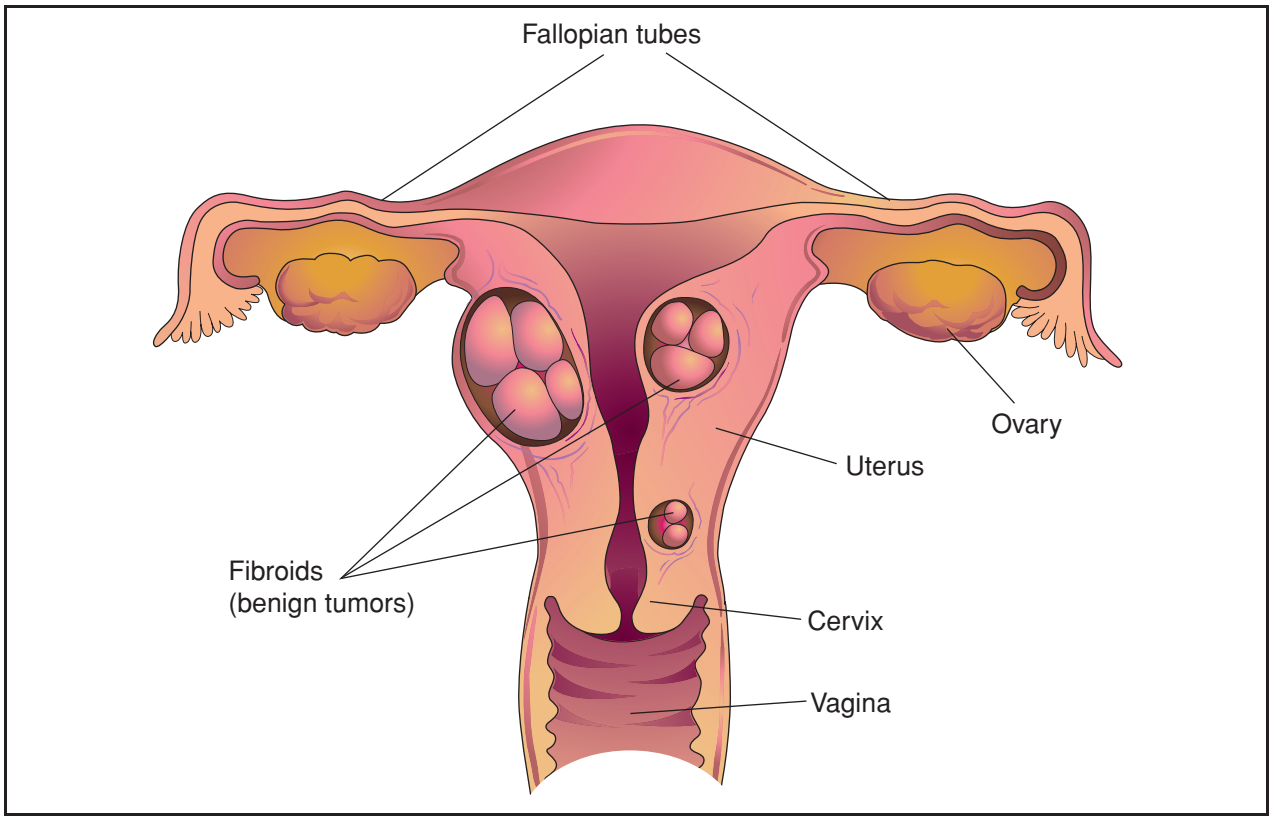
Demographics

Uterine fibroids are extremely common. About 25% of women in their reproductive years have noticeable fibroids. There are probably many more women who have tiny fibroids that are undetected.

Fibroids develop between the ages of 30 and 50. They are never seen in women less than 20 years old. After **menopause**, if a woman does not take estrogen, fibroids shrink. It appears that African–American women are much more likely to develop uterine fibroids.

Description

Fibroids are divided into different types, depending on the location. Submucous fibroids are found in the uterine cavity; intramural fibroids grow on the wall of the uterus; and subserous fibroids are located on the outside of the uterus. Many fibroids are so large that they fit into more than one category. The symptoms caused by fibroids are often related to their location.



Uterine fibroids are benign growths of uterine muscle and are very common. They are divided into three types, depending on the location. Submucous fibroids are found in the uterine cavity; intramural fibroids grow on the wall of the uterus; and subserous fibroids are located outside of the uterus. *(Illustration by Electronic Illustrators Group. Reproduced by permission of Gale, a part of Cengage Learning.)*

Causes and symptoms

No one knows exactly what causes fibroids. However, the growth of fibroids appears to depend on the hormone estrogen. Fibroids often grow larger when estrogen levels are high, as in **pregnancy**. Medications that lower the estrogen level can cause fibroids to shrink.

The signs and symptoms of fibroids include:

- Heavy uterine bleeding. This is the most common symptom, occurring in 30% of women who have fibroids. The excess bleeding usually happens during the menstrual period. Flow may be heavier, and periods may last longer. Women who have submucous or intramural fibroids are most likely to have heavy uterine bleeding.
- Pelvic pressure and pain. Large fibroids that press on nearby structures such as the bladder and bowel can cause pressure and pain. Larger fibroids tend to cause worse symptoms.
- Infertility. This is a rare symptom of fibroids. It probably accounts for less than 3% of infertility cases. Fibroids can cause infertility by compressing the uterine cavity. Submucous fibroids can fill the uterine cavity and interfere with implantation of the fertilized egg.
- Miscarriage. This is also an unusual symptom of fibroids, probably accounting for only a tiny fraction of the miscarriages that occur.
- Pregnancy complications. Fibroids can greatly increase in size during pregnancy, because of increased levels of estrogen. They can cause pain and even lead to premature labor.

Diagnosis

A health care provider can usually feel fibroids during a routine pelvic examination. Ultrasound can be used to confirm the diagnosis, but this is not necessary.

Treatment

Not all fibroids cause symptoms. Even fibroids that do cause symptoms may not require treatment. In the majority of cases, symptoms are inconvenient and unpleasant, but do not result in health problems.

KEY TERMS

Anemia—Low blood count.

GnRH antagonists—A group of medications that affect the reproductive hormones. These medications are used to treat fibroids, endometriosis, and infertility.

Hysterectomy—Removal of the uterus (with or without removal of the ovaries) by surgery. The surgery can be performed through an incision in the abdomen, or the uterus can be removed through the vagina.

Menopause—The end of the reproductive years, signaled by the end of menstrual periods. Also known as "the change."

Osteoporosis—A bone disorder in which the bones become increasingly less dense and more brittle.

Occasionally, fibroids lead to such heavy menstrual bleeding that the woman becomes severely anemic. In these cases, treatment of fibroids may be necessary. Very large fibroids are much harder to treat. Therefore, many doctors recommend treatment for moderately–sized fibroids, in the hopes of preventing them from growing into large fibroids that cause worse symptoms.

The following are possible treatment plans:

- Observation. This is the most common plan. Most women already have symptoms at the time their fibroids are discovered, but feel that they can tolerate their symptoms. Therefore, no active treatment is given, but the woman and her physician stay alert for signs that the condition might be getting worse.
- Hysterectomy. This involves surgical removal of the uterus, and it is the only real cure for fibroids. In fact, 25% of hysterectomies are performed because of symptomatic fibroids. By the time a woman has a hysterectomy for fibroids, she has usually endured several years of worsening symptoms because fibroids tend to grow over time. A gynecologist can remove a fibroid uterus during either an abdominal or a vaginal hysterectomy. The choice depends on the size of the fibroids and other factors such as previous births and previous surgeries.
- Myomectomy. In this surgical procedure only the fibroids are removed; the uterus is repaired and left in place. This is the surgical procedure many women choose if they are not finished with childbearing. At first glance, it seems that this treatment is a middle ground between observation and hysterectomy. However, myomectomy is actually a difficult surgical procedure, more difficult than a hysterectomy. Myomectomy often causes significant blood loss, and blood transfusions may be required. In addition, some fibroids are so large, or buried so deeply within the wall of the uterus, that it is not possible to save the uterus, and a hysterectomy must be done, even though it was not planned. There are exceptions to this, however. Sometimes, fibroids grow on a stalk (pedunculated fibroids), and these are easy to remove.
- Medical treatment. Since fibroids are dependent on estrogen for their growth, medical treatments that lower estrogen levels can cause fibroids to shrink. A group of medications known as GnRH antagonists can dramatically lower estrogen levels. Women who take these medications for three to six months find that their fibroids shrink in size by 50% or more. They usually experience dramatic relief of their symptoms of heavy bleeding and pelvic pain.

Unfortunately, GnRH antagonists cause unpleasant side effects in over 90% of women. The therapy is usually used for only three months, and should not be used for more than six months because the risk of developing brittle bones (**osteoporosis**) begins to increase. Once treatment is stopped, fibroids begin to grow back to their original size. Within six months, most of the old symptoms return. Therefore, GnRH agonists cannot be used as long–term solution. At the moment, treatment with GnRH antagonists is used mainly in preparation for surgery (**myomectomy** or **hysterectomy**). Shrinking the size of fibroids makes surgery much easier, and reducing heavy bleeding allows a woman to build up her blood count before surgery.

Fibroids can cause problems during pregnancy because they often grow in size. Large fibroids can cause **pain** and lead to **premature labor**. Fibroids cannot be removed during pregnancy because of the risk of injury to the uterus and hemorrhage. GnRH antagonists cannot be used during pregnancy. Treatment is limited to pain medication and medication to prevent premature labor, if necessary.

Prognosis

Many women who have fibroids have no symptoms or have only minor symptoms of heavy menstrual bleeding or pelvic pressure. However, fibroids tend to grow over time, and gradually cause more

symptoms. Many women ultimately decide to have some form of treatment. Currently, hysterectomy is the most popular form of treatment.

Prevention

Uterine fibroids cannot be prevented.

Uveitis

Definition

Uveitis is an inflammation of the uveal tract, which lines the inside of the eye behind the cornea. Much of the uvea lies between the retina and the tough, outer sclera. The uveal tract has three parts: the iris, the ciliary body, and the choroid. Uveitis is categorized according to the part of the uveal tract that is affected. Anterior uveitis is an inflammation of the front part of the uveal tract; it includes inflammation of the iris (iritis) and inflammation of the iris and the ciliary body (iridocyclitis). Posterior uveitis is an inflammation of the part of the uveal tract behind the lens of the eye. It includes inflammation of the choroid (choroiditis) and inflammation of the choroid and retina (chorioretinitis). Uveitis that affects the entire uveal tract is called panuveitis or diffuse uveitis.

Description

The uveal tract is made up of the iris, ciliary body, and choroid. The iris is the colored part of the eye. The ciliary body is inside the eye and produces a fluid called aqueous humor. Ciliary muscles aid in accommodation, the process of changing the shape of the lens in the eye to see things at various distances. The choroid lines the back of the eye and has many blood vessels. It helps nourish part of the retina. The choroid lies between the retina and outermost sclera.

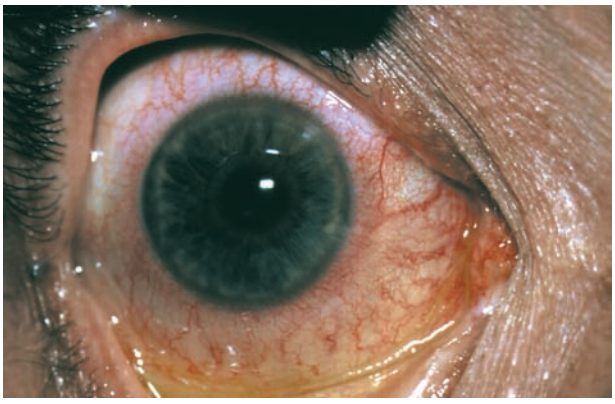
Uveitis may either persist for a long time (chronic) or have a short-term duration (acute). Anterior uveitis is classified as either granulomatous or nongranulomatous. The distinction is based on the disease agents that were considered responsible for the condition. At one time, it was thought that granulomatous uveitis was caused by **tuberculosis** bacilli whereas nongranulomatous uveitis was thought to be caused by streptococci. The distinction is still used even though the causes of uveitis are now understood differently.

In most cases, uveitis affects only one eye, although posterior uveitis sometimes involves both eyes. About 60% of cases develop within the eye itself, but 40% are associated with systemic diseases or disorders ranging from **toxoplasmosis** to **syphilis**. Many of these are diseases of childhood and adolescence. Uveitis does not appear to run in families or to be associated with lifestyle choices, occupational history, geographical location, or environmental factors.

Uveitis is a serious condition that may develop rapidly and cause lasting damage to the eye. Patients who think they may have chronic uveitis should seek evaluation and treatment by an ophthalmologist (a physician who specializes in diseases of the eye) as soon as possible. If the patient has a sudden loss of vision and the eye looks inflamed, the patient should go *immediately* to the doctor for emergency treatment.

Causes and symptoms

The causes of uveitis are not fully understood, but they can be a result of trauma, allergy, or a response to a systemic or ocular disease. Uveitis may be a type of immune-response mechanism. In people with



This person has acute iritis, or inflammation of the iris. Symptoms include pain in the eye or forehead and reddening of the margin of the iris. Treatment requires total rest of the eye (dark glasses and atropine drops which paralyze the muscles of accommodation), accompanied by application of corticosteroids. *(Photo Researchers, Inc.)*

impaired immune systems, uveitis may be due to an infection.

Chronic uveitis is often associated with systemic disorders (e.g., **Lyme disease**, **sarcoidosis**, or juvenile **rheumatoid arthritis**).

Anterior uveitis

The so-called classic symptoms of anterior uveitis—severe **pain**; redness, particularly around the edge of the iris; and extreme sensitivity to light (photophobia)—occur mostly in acute uveitis. In anterior uveitis, the doctor will see a so-called "flare and cell" pattern when looking into the watery fluid (aqueous humor) between the cornea and the lens of the patient's eye. The iris may adhere to the lens, thus increasing the intraocular pressure. There may be nodules on the iris. There may be tearing and the pupil may be constricted and nonreactive. In severe cases of anterior uveitis, there may be hypopyon (a small amount of pus or collection of white cells) visible when the doctor examines the eye.

GRANULOMATOUS UVEITIS. In granulomatous uveitis, there will be large yellowish-white cells visible on the back of the cornea and possibly some small nodules on the iris. Granulomatous uveitis is usually less acute than the nongranulomatous form; the eye is only mildly inflamed and the patient's vision is somewhat blurred.

Granulomatous uveitis can be produced by syphilis, toxoplasmosis, cytomegalovirus, sarcoidosis, tuberculosis, or Vogt-Koyonagi-Harada syndrome (VKH). VKH is marked by severe uveitis associated with hair loss, **hearing loss**, loss of pigment in the eyelashes and brows, and headaches. It occurs most commonly in Asians.

NONGRANULOMATOUS UVEITIS. In nongranulomatous uveitis, the cells visible on the cornea are smaller, and there are no masses on the iris. This type of anterior uveitis is, however, more painful. The eye is red and the patient experiences both photophobia and loss of vision.

Systemic diseases that can cause nongranulomatous uveitis include **ankylosing spondylitis**, **Reiter's syndrome**, **psoriasis**, ulcerative **colitis**, **Behcet's syndrome**, Lyme disease, and **Crohn's disease**. Children—especially girls—with anterior uveitis should be screened for juvenile rheumatoid arthritis (JRA).

Posterior uveitis

The symptoms of posterior uveitis are sometimes subtle. The patient may notice blurred or hazy vision, or floating black spots before the eyes. There may be pain and photophobia. The iris may attach to the lens in the eye, thus increasing intraocular pressure.

Posterior uveitis may be acute or chronic. It is more likely to involve both eyes. When the doctor examines the eye, cells may be seen in the vitreous humor, which is the normally transparent gel that fills the eyeball behind the lens. There will be yellowish or dark areas of inflammation on the choroid and the retina. The blood vessels in the retina develop a sheath or covering of inflammatory tissue. In severe cases, the vitreous humor is so cloudy that the doctor cannot see the retina at the back of the eye.

PARS PLANITIS. Pars planitis is an inflammation of the pars plana, which is a part of the ciliary body. Pars planitis usually occurs in older children or young adults, and can develop into posterior uveitis.

The diseases that cause granulomatous uveitis may also cause posterior uveitis.

Diagnosis

The eye doctor will examine the patient's eyes with a slit lamp in order to rule out **conjunctivitis** and certain types of glaucoma. The slit lamp is an instrument that combines a binocular microscope with a special light. The slit lamp can shine a narrow beam of very bright light into the eye and allow the doctor to examine the front part of the eye in detail. The slit-lamp exam is not painful, however if the patient is sensitive to light there will be discomfort.

KEY TERMS

Choroid—The part of the uveal tract behind the ciliary body. The choroid underlies and nourishes the retina and absorbs scattered light.

Ciliary body—The part of the uveal tract between the iris and the choroid.

Cornea—The transparent front part of the eye that covers the iris and pupil.

Flare and cell—A pattern revealed by slit-lamp examination that indicates uveitis. Flare and cell resembles light filtered through smoke.

Hypopyon—A small amount of pus or collection of white cells that is visible in the front of the eye in severe cases of anterior uveitis.

Iris—The circular membrane that forms the colored portion of the eye and expands or contracts around the pupil.

Photophobia—Extreme sensitivity to light. Photophobia is a major symptom of acute uveitis.

Pupil—The opening in the center of the iris that allows light to pass through to the retina.

Retina—The innermost membrane at the back of the eyeball on which images are projected by the lens.

Slit lamp—An instrument that combines a binocular microscope with special lights. It allows an eye doctor to examine the front portion of the eye.

Uveal tract—The pigmented membrane that lines the back of the retina of the eye and extends forward to include the iris. The uveal tract is sometimes called the uvea and has three parts: the iris, the choroid, and the ciliary body.

Vitreous humor—The clear gel-like substance that fills the eyeball behind the lens.

The absence of a discharge from the eye and the absence of infectious organisms in a laboratory smear usually rule out conjunctivitis. In addition, the size of the pupil is often small in uveitis whereas it is normal in conjunctivitis. In acute glaucoma, the patient has severe pain, the cornea of the eye is cloudy, and the pressure level of the fluid inside the eye is abnormally high, whereas in uveitis the pain is moderate, the cornea is clear, and the fluid pressure is normal or possibly lower or slightly above normal. The doctor may also use the slit lamp and another lens to examine the back of the eye to get a good look at the retina and choroid. Other instruments, such as a hand-held ophthalmoscope or a binocular indirect ophthalmoscope, can be used to examine the back of the eye. There should be no discomfort with these tests except if the patient is sensitive to the bright light.

Laboratory testing

Laboratory testing is used to rule out conjunctivitis in some patients. The doctor wipes the inside of the patient's eyelid with a swab in order to obtain a sample for testing. Although blood tests are not necessary to diagnose uveitis by itself, they are used to diagnose the cause if the doctor suspects that toxoplasmosis or another systemic disease is responsible for the uveitis.

Treatment

Uveitis is generally treated by an ophthalmologist because therapy requires topical and oral medications; however, some optometrists (O.D.) are state licensed to use therapeutic medications. Other doctors may be involved in treating the underlying disease, if the patient has one, and in monitoring the patient's responses to medications.

Anterior uveitis is treated with corticosteroid drops; in severe cases, the patient may be given steroid injections in the area of the eye or oral **steroids**. Atropine sulfate drops may be given to dilate the patient's pupil. Posterior uveitis is treated with **systemic corticosteroids**. It is usually not necessary to dilate the pupil.

Prolonged steroid use may increase intraocular pressure, thereby increasing the risk of glaucoma. Steroid use has also been connected to cataract formation. Patients should be monitored closely and frequently.

Prognosis

The prognosis depends upon the location of the uveitis, on whether it is chronic or acute, and on the promptness of treatment. The prognosis for untreated uveitis is poor. Untreated anterior uveitis usually progresses to posterior uveitis, resulting in **cataracts**, scar tissue, and eventual glaucoma. If treated promptly, anterior uveitis usually clears up in several days or

weeks, but is likely to recur. Posterior uveitis usually results in some permanent loss or blurring of vision.

Prevention

Patients with anterior uveitis should be warned about the possibility of recurrence and instructed about its symptoms, especially inflammation of the iris. They should be advised to seek treatment at once at the first signs of recurrence.

V

Vaccination

Definition

Vaccination is the injection of a weakened or dead microbe in a person to stimulate the immune system against the microbe and prevent disease.

Purpose

The first vaccine was developed in 1796 by English physician Edward Jenner who took a few drops of the fluid seeping from a pustule of a cowpox-infected woman and injected it into a healthy young boy. Six weeks later, Jenner injected the boy with fluid from a **smallpox** pustule, and the boy did not develop dreaded smallpox, a devastating disease that killed over a million people each year in Europe. Survivors were often left with blindness, deep **scars**, and deformities. By the start of the twentieth century, vaccines for smallpox, **rabies**, **diphtheria**, **typhoid fever**, and **plague** had been developed. Vaccines are now available against more than 20 infectious diseases such as **influenza**, **pneumonia**, **whooping cough**, **rubella**, rabies, **meningitis**, and **hepatitis B**.

Vaccines are medicines that contain weakened or dead bacteria or viruses. When a person is given a vaccine, his or her immune system responds by producing proteins called antibodies. When the person is later exposed to live bacteria or viruses of the same kind that were in the vaccine, the antibodies destroy those organisms and prevent them from making the person sick. Vaccines usually stimulate the cellular immune system as well. In other words, the person becomes immune to the disease that the organisms normally cause. The process of building up immunity by being given a vaccine is called immunization.

Vaccines are used in several ways. Some, such as the rabies vaccine, normally are given only when a person is likely to have been exposed to the virus that causes the disease, for example, through a dog bite. Others are given to travelers planning to visit countries where certain diseases such as typhoid **fever** or **yellow fever** are common. Vaccines such as the influenza vaccine, or the "flu shot," are given mainly to specific groups of people who are at high risk of developing influenza or its complications. There are also vaccines that are given to almost everyone, such as the ones that prevent diphtheria, **tetanus**, **polio**, and **measles**.

Children routinely are given a series of vaccinations that begin at birth. Given according to a specific schedule, these vaccinations protect against hepatitis B, diphtheria, tetanus, whooping **cough**, measles, **mumps**, rubella (German measles), varicella (**chickenpox**), polio, pneumococcus and *Haemophilus influenzae* type b (Hib disease, a major cause of spinal meningitis) and, in some states, **hepatitis A**. This series of vaccinations is

An allergic reaction to a vaccination shot. *(© Lester V. Bergman/Corbis.)*

recommended by the American Academy of Family Physicians, the American Academy of Pediatrics, and the Centers for Disease Control and Prevention (CDC). It is required in all states before children can enter school. All states will make exceptions for children who have medical conditions such as **cancer** that prevent them from having vaccinations, and some states also will make exceptions for children whose parents object for religious or other reasons.

Additional vaccines are available for preventing rotavirus infection (given to infants), **anthrax**, **cholera**, **Japanese encephalitis**, meningococcal meningitis, plague, **tuberculosis**, typhoid fever, **H1N1** (also known as swine flu), and yellow fever.

Description

Most vaccines are given as injections, but a few are given by mouth or as a nasal spray.

Some vaccines are combined in one injection, such as the measles-mumps-rubella (MMR) or diphtheria-tetanus-pertussis (DTaP) combinations.

Recommended dosage

The recommended dosage depends on the type of vaccine and may be different for different patients. Dosage is standardized for each specific type and usually varies based on age. The healthcare professional who gives the vaccine will determine the proper dose.

A vaccination health record helps parents and health care providers keep track of a child's vaccinations. The record should be started when the child has his or her first vaccination and should be updated with each additional vaccination. While most physicians follow the recommended vaccination schedule, parents should understand that some flexibility is allowed, for example if the child is sick at the time the vaccination is due. Slight departures will not prevent the child from developing immunity, as long as all the vaccinations are given at approximately the right times. The child's physician is the best person to decide when each vaccination should be given.

Anyone planning a trip to another country should check to find out what vaccinations are needed. Some vaccinations must be given as much as 12 weeks before the trip, so getting this information early is important. Many major hospitals and medical centers have travel clinics that can provide this information. The Traveler's Health Section of the Centers for Disease Control and Prevention also has information on vaccination requirements.

ALBERT BRUCE SABIN (1906–1993)

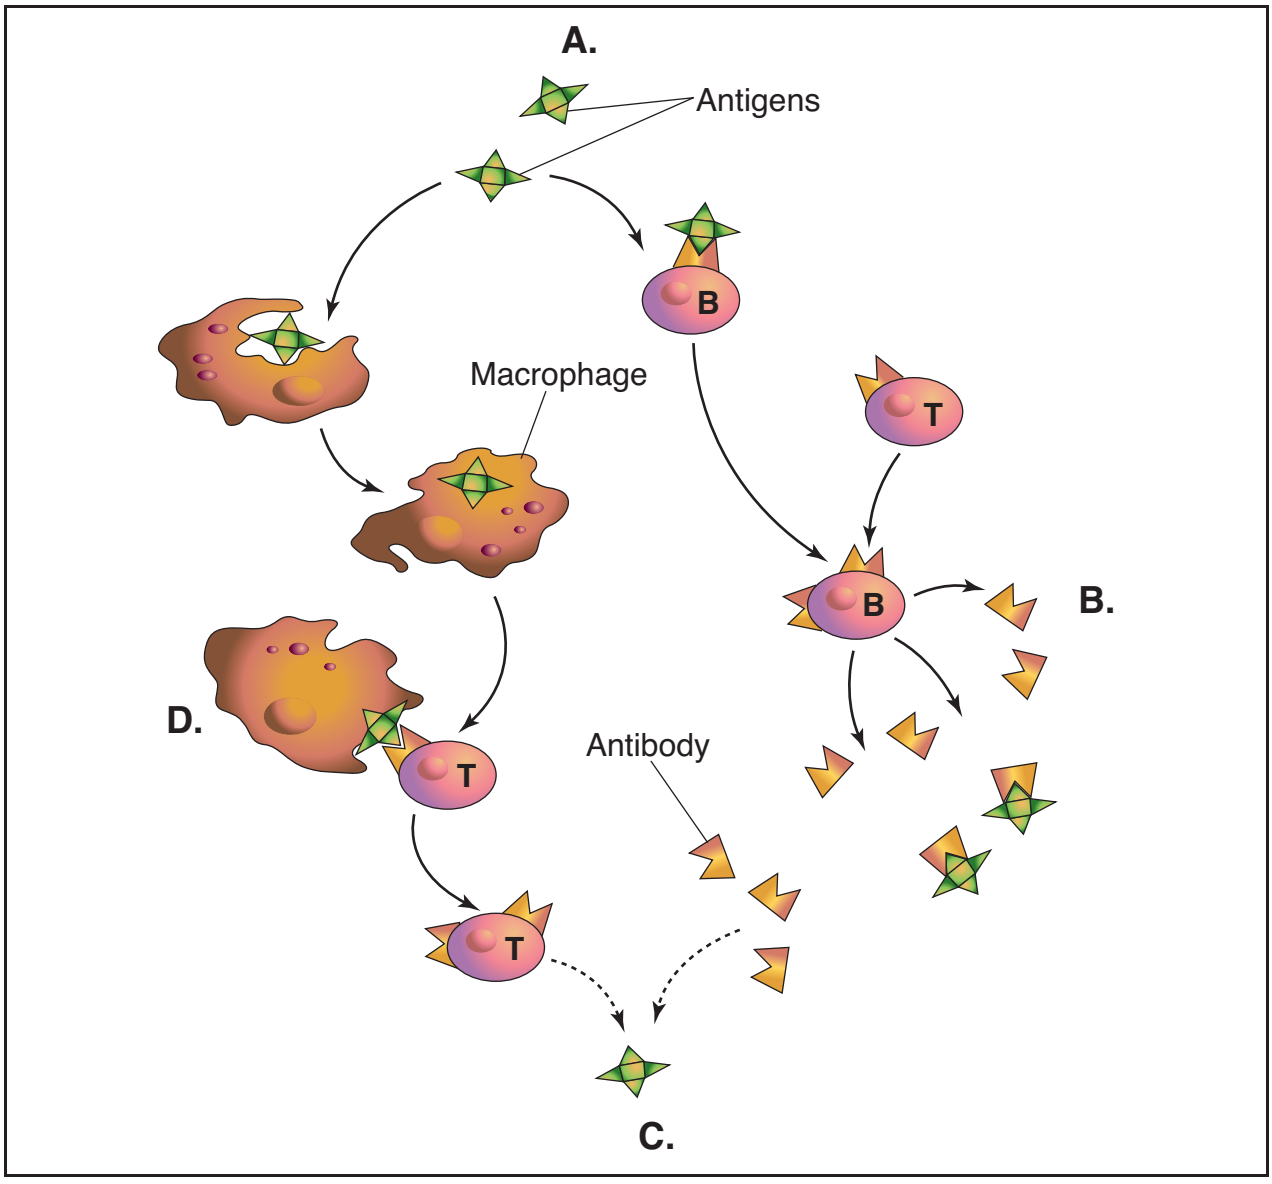
Albert Bruce Sabin was born on August 26, 1906, in Bialystok, Russia, to Jacob and Tillie Sabin. In order to escape extreme poverty, the Sabins immigrated to the United States and settled in Paterson, New Jersey. Following his graduation from high school in 1923, Sabin was able to attend dentistry school at New York University due to his uncle's generous offer for financing. However, after reading Paul deKruif's *Microbe Hunters* he became intrigued by virology and the idea of curing epidemic diseases. After two years of dentistry school, Sabin decided to switch to medicine, earning his M.D. in 1931. Sabin completed his residency and internship in the United States and then went to London to conduct research.

Sabin returned to the United States in 1935 to resume his research of polio at the Rockefeller Institute. In 1953, Jonas Salk announced that he had created a dead-virus polio vaccine that was safe, but soon after its administration many people died. Sabin, however, wanted to create a live-virus vaccine, which he felt would be safer. Sabin diluted three strains of the polio virus and tested these on himself, his family, and other volunteers. These live-virus vaccines (given orally) proved safe and effective and soon became the vaccinations of choice around the world. Sabin's published works include *Viruses and Cancer: A Public Lecture in Conversational Style* (1965), *Behavior of Chimpanzee-Avirulent Poliomyelitis Viruses in Experimentally Infected Human Volunteers* (1955), and *Recent Advances in Our Knowledge of Dengue and Sand Fly Fever* (1955). Sabin died of congestive heart failure on March 3, 1993.

Precautions

Vaccines are not always 100% effective, and there is no way to predict whether a vaccine will fail to provide adequate immunity in any particular person. To be most effective in preventing disease outbreaks, vaccination programs depend on whole communities participating. The more people who are vaccinated, the lower everyone's risk of being exposed to a disease. Even people who do not develop immunity through vaccination are safer when their friends, neighbors, children, and coworkers are immunized. In addition to vaccines, hand washing and proper hygiene are the most effective means for preventing the spread of infectious diseases.

Like most medical procedures, vaccination has risks as well as substantial benefits. Anyone who takes



How vaccines work: A. Vaccines contain antigens (weakened or dead viruses, bacteria, and fungi that cause disease and infection). When introduced into the body, the antigens stimulate the immune system response by instructing B cells to produce antibodies, with assistance from T-cells. B. The antibodies are produced to fight the weakened or dead viruses in the vaccine. C. The antibodies "practice" on the weakened viruses, preparing the immune system to destroy real and stronger viruses in the future. D. When new antigens enter the body, white blood cells called macrophages engulf them, process the information contained in the antigens, and send it to the T-cells so that an immune system response can be mobilized. *(Illustration by Electronic Illustrators Group. Reproduced by permission of Gale, a part of Cengage Learning.)*

a vaccine should make sure he or she is fully informed about both the benefits and the risks. Any questions or concerns should be discussed with a physician or other health care provider. The Centers for Disease Control and Prevention (CDC) offers substantial information on immunizations and vaccinations.

Vaccines may cause problems for people with certain **allergies**. Patients who have allergies to:

- antibiotics neomycin or polymyxin B should not take rubella vaccine, measles vaccine, mumps vaccine, or the combined MMR vaccine
- baker's yeast should not take the hepatitis B vaccine
- antibiotics such as gentamicin sulfate, streptomycin sulfate or other aminoglycosides should check with their physicians before taking influenza vaccine, as some influenza vaccines contain small amounts of these drugs

KEY TERMS

Anthrax—An infectious disease caused by a type of bacterium. The disease can be passed from animals to people and usually is fatal. Symptoms include sores on the skin.

Antibodies—Proteins that are normally produced by specialized white blood cells after stimulation by a foreign substance (antigen) and that act specifically against the antigen in an immune response.

Antigen—Any foreign substance, usually a protein, that stimulates the body's immune system to produce antibodies.

Bacteria—Tiny, single-celled forms of life that cause many diseases and infections.

Cholera—An infection of the small intestine caused by a type of bacterium. The disease is spread by drinking water or eating seafood or other foods that have been contaminated with the feces of infected people. It occurs in parts of Asia, Africa, Latin America, India, and the Middle East. Symptoms include watery diarrhea and exhaustion and is often fatal to young children and the elderly.

Cowpox—A mild disease in cows that is caused by a poxvirus.

Diphtheria—A serious, infectious disease that produces a toxin (poison) and an inflammation in the membrane lining of the throat, nose, trachea, and other tissues.

Encephalitis—Inflammation of the brain, usually caused by a virus. The inflammation may interfere with normal brain function and may cause seizures, sleepiness, confusion, personality changes, weakness in one or more parts of the body, and even coma.

Feces—The solid waste that is left after food is digested. Feces form in the intestines and pass out of the body through the anus. Also called stool.

Guillain-Barré syndrome (GBS)—A disease of the nerves with symptoms that include sudden numbness and weakness in the arms and legs, sometimes leading to paralysis. The disease is serious and requires medical treatment, but most people recover completely.

H1N1 (Swine Flu)—A disease that was originally found in pigs and can be passed from animal to human or human to human. Symptoms of H1N1 include fever, cough, chills, fatigue, headache, and body aches.

Immune system—The body's natural defenses against disease and infection.

Immunization—Administering a vaccine that stimulates the body to create antibodies to a specific disease (immunity) without causing symptoms of the disease.

Infectious disease—Any disease caused by invasion of a pathogen that subsequently grows and multiplies in the body.

- eggs should not take vaccines grown in the fluids of chick embryos including those for influenza, measles, and mumps

In general, anyone who has had an unusual reactions to a vaccine in the past should inform the physician before taking the same kind of vaccine again. The physician also should be told about any allergies to foods, medicines, preservatives, or other substances.

People with certain other medical conditions should be cautious about taking vaccines. Influenza vaccine, for example, may reactivate the rare Guillain-Barré syndrome (GBS) in people who have had it before. This vaccine also may worsen illnesses that involve the lungs, such as **bronchitis** or pneumonia. Vaccines that cause fever as a side effect may trigger seizures in people who have a history of seizures caused by fever.

Certain vaccines are not recommended for use during **pregnancy**, but some may be given to women at especially high risk of getting a specific disease such as polio. Vaccines also may be given to pregnant women to prevent medical problems in their babies. For example, vaccinating a pregnant woman with tetanus toxoid can prevent her baby from getting tetanus at birth.

Women should avoid becoming pregnant for three months after taking rubella vaccine, measles vaccine, mumps vaccine, or the combined MMR as these vaccines could cause problems in the unborn baby.

Women who are **breastfeeding** should check with their physicians before taking any vaccine.

Side effects

Most side effects from vaccines are minor and easily treated. The most common are **pain**, redness, and swelling

Inflammation—Pain, redness, swelling, and heat that usually develop in response to injury or illness.

Influenza—A disease caused by viruses that infect the respiratory tract.

Measles—An acute and highly contagious viral disease marked by distinct red spots followed by a rash that occurs primarily in children.

Meningitis—Inflammation of tissues that surround the brain and spinal cord.

Microbe—A microorganism, especially a bacterium, that causes disease.

Mumps—An acute and highly contagious viral illness that usually occurs in childhood.

Pathogen—A disease-causing microorganism.

Plague—A highly infectious disease that can be fatal if not treated promptly. The bacteria that cause plague mainly infect rats, mice, squirrels, and other wild rodents. The disease is passed to people through fleas. Infected people can then spread the disease to other people.

Rabies—A rare but serious disease caused by a virus carried in saliva. It is transmitted when an infected animal bites a person.

Rubella—A contagious viral disease that is milder than typical measles but is damaging to the fetus when it occurs early in pregnancy. Also called German measles.

Seizure—A sudden attack, spasm, or convulsion.

Smallpox—A highly contagious viral disease characterized by fever, weakness, and skin eruption with pustules that form scabs that slough off leaving scars.

Tuberculosis—An infectious disease that usually affects the lungs, but may also affect other parts of the body. Symptoms include fever, weight loss, and coughing up blood.

Typhoid fever—An infectious disease caused by a type of bacterium. People with this disease have a lingering fever and feel depressed and exhausted. Diarrhea and rose-colored spots on the chest and abdomen are other symptoms. The disease is spread through poor sanitation.

Virus—A tiny, disease-causing particle that can reproduce only in living cells.

Whooping cough—An infectious disease, also called pertussis, especially of children that is caused by a bacterium and is marked by a convulsive, spasmodic cough, sometimes followed by a shrill intake of breath.

Yellow fever—An infectious disease caused by a virus. The disease, which is spread by mosquitoes, is most common in Central and South America and Central Africa. Symptoms include high fever, jaundice (yellow eyes and skin) and dark-colored vomit, a sign of internal bleeding. Yellow fever can be fatal.

at the site of the injection. Some people may develop a fever or a rash. In rare cases, vaccines may cause severe allergic reactions, swelling of the brain, or seizures. Anyone who has an unusual reaction after receiving a vaccine should contact a physician immediately.

Interactions

Vaccines may interact with other medicines and medical treatments. When this happens, the effects of the vaccine or the other medicine may change or the risk of side effects may be greater. For example, **radiation therapy** and cancer drugs may reduce the effectiveness of many vaccines or may increase the chance of side effects. Anyone who takes a vaccine should let the physician know all other medicines he or she is taking and should ask whether the possible interactions could interfere with the effects of the vaccine or the other medicines.

Vaccines *see* **Vaccination**

Vaginal pain

Definition

Pain in the vaginal canal is usually associated with an underlying medical and/or psychological condition.

Demographics

Approximately 50–85% of the causes of vaginal pain are due to organic (medical) conditions. However, it is typical for the medical condition to be compounded by psychological issues such as depression, problems associated with sexual identity, or problems relating to personal female medical conditions (sometimes experienced by **breast cancer** and **hysterectomy** patients). The overall prevalence for vaginal pain experienced during sexual intercourse (**dyspareunia**), is 20% (15% of women and 57% of men).

Description

The vagina has three physiological functions: an outflow duct for menstrual discharge, to receive the penis during sexual intercourse, and as the birthing canal. Vaginal pain is experienced usually during vaginal manipulation or sexual intercourse. The primary entity concerns dyspareunia.

Causes and symptoms

Causes can be categorized as organic, due to a medical condition, and/or psychological difficulties. Medical conditions can include chronic diseases, minor ailments, breast **cancer**, and medications. Psychological cause can be related to physical or **sexual abuse**. **Pregnancy** and hormonal changes (decreased estrogen) have significant negative impact on sexual activity, desire, and satisfaction. Dyspareunia can be divided into three types of pain: superficial, vaginal, and deep. Superficial pain is associated with attempted penetration. This condition is usually caused by changes in anatomy, irritative condition, or **vaginismus**. Vaginal pain is associated with friction, indicating a problem with lubrication and/or arousal disorders. Deep pain is related to thrusting and is indicative of pelvic disease or an inability for **pelvic relaxation**.

Diagnosis

Diagnosis must be pursued with diligence and in a comprehensive manner. A careful history and **physical examination** is essential. Procedures that can be used include surgical investigation (**laparoscopy**) and treatment of the underlying cause(s).

Treatment

Treatment is directed at diagnosing the underlying condition, which can be medical and/or psychological cause(s). Treatment can include surgery, hormonal therapy (replacements), **psychotherapy**, and pain control protocols.

KEY TERMS

Laparoscopic surgery—A surgical procedure to correct or diagnose an underlying disease.

Prognosis

Prognosis depends on the primary cause. If treatment is aggressively pursued and patient compliance is satisfactory, the overall outcome is favorable.

Prevention

There are no precise preventive measures since the condition can result from normal **aging** and/or progressively worsening psychological disease.

Vaginismus

Definition

Vaginismus is a **sexual dysfunction** in which the muscles of the outer third of the vagina involuntarily contract or spasm during attempts at vaginal penetration, thereby closing the vagina.

Demographics

Sexual disorders are common among women, yet many cases go unreported and there is little accurate data regarding the incidence of specific problems. Vaginismus is believed to be uncommon. It is thought to occur most often in women of higher educational attainment and socioeconomic status.

Description

Vaginismus is a reflex response to pressing on the vagina. Women with vaginismus do not intentionally contract their vaginal muscles; rather the muscles of the outer vagina tighten automatically, often causing **pain**. Vaginismus can occur with any type of attempted vaginal penetration such as a penis, speculum, tampon, or other object. Sometimes it occurs with mere touching. Pushing harder increases the pain and most women with vaginismus cannot tolerate sexual intercourse. Vaginismus does not affect a woman's desire for sexual intercourse. Most women with vaginismus enjoy sexual activity that does not involve penetration and many have orgasms through clitoral stimulation.

There are different types of vaginismus:

- Lifelong vaginismus is the most common type and begins the first time vaginal penetration is attempted.
- Acquired vaginismus begins after a period of normal sexual functioning, often after a physical condition causes an episode of painful intercourse or after a woman has intercourse while emotionally distressed.
- General vaginismus occurs whenever vaginal penetration is attempted.
- Situational vaginismus occurs only in specific situations, such as with a certain sexual partner or during a gynecological examination.

Risk factors

Risk factors for vaginismus include physical conditions that cause painful intercourse, as well as sexual trauma or negative feelings about sex.

Causes and symptoms

There are many possible causes for vaginismus, but sometimes no cause can be determined. Vaginismus sometimes develops following painful intercourse caused by a physical condition. Such conditions include:

- infections of the vulva or vagina
- vulvodynia or vulvar vestibulitis, a stinging or burning around the opening to the vagina
- chronic pelvic pain from an underlying medical condition

KEY TERMS

Cognitive behavioral therapy (CBT)—Psychotherapy that emphasizes the substitution of desirable patterns of thinking for undesirable patterns.

Coitus—Sexual intercourse.

Desensitization—The elimination of an emotional response, such as fear or anxiety, to specific stimuli.

Kegel exercises—Repetitive contractions to tone the pubococcygeal muscle of the pelvic floor for enhancing sexual response during intercourse or controlling incontinence.

Pelvic exam—A gynecological exam of the female reproductive organs.

Vulva—The external female genital organs, including the labia majora, labia minora, clitoris, and vestibule of the vagina.

Vulvar vestibulitis—A localized inflammation of the vestibule—the region immediately surrounding the opening of the vagina and the urethra.

Vulvodynia—A chronic burning, stinging, or irritation of the vulva.

- scars on the vagina from injury, childbirth, or surgery
- radiation therapy
- menopause or a medical treatment that affects female hormone levels
- irritation from douches, spermicides, or the latex in condoms

There are also various psychological causes of vaginismus. A common cause of vaginismus is the belief that sex is wrong, sinful, or "dirty"—often resulting from parental or religious teachings. In addition, a painful first sexual experience can cause the body to react as if all sexual intercourse will be painful. A traumatic childhood experience, such as sexual molestation, may cause lifelong vaginismus, while acquired vaginismus often results from **sexual assault** or **rape**. Women who feel threatened or powerless in a relationship may subconsciously tighten their vaginal muscles in defense or silent defiance. Another cause is fear of becoming pregnant.

According to the psychiatric handbook, the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Editon-Text Revision (DSM-IV-TR)*, a diagnosis of vaginismus requires that the response is due to psychological factors or a combination of psychological and medical factors, but not to medical factors alone.

The major symptom of vaginismus is the severe contraction of the outer vaginal muscles as the vagina is about to be penetrated. This may completely prevent penetration or make it difficult and painful. Women with vaginismus may be unable to consciously relax their vaginal muscles even when they truly desire to have sexual intercourse or allow penetration. Pelvic examinations may also be painful Some women cannot tolerate inserting a tampon or have never even tried.

Diagnosis

Examination

Diagnosing sexual disorders such as vaginismus is often very difficult, primarily due to discomfort or embarrassment about sexual discussions, even with a personal physician. Cultural norms and taboos often deter women from seeking help. Sometimes women are more comfortable consulting a physician if they are accompanied by a close friend or family member.

Involuntary spasm during a pelvic examination by a gynecologist or other women's healthcare specialist can confirm a diagnosis of vaginismus. The exam must be conducted as slowly and gently as possible. Physicians must explain what they are doing in detail. The woman may be offered a mirror and asked to guide the physician's hand or instruments into the vagina. Sometimes treatment for vaginismus must be initiated before a pelvic examination can be completed.

A complete physical exam and medical and sexual history are necessary to rule out other causes of painful sexual intercourse. The exam may reveal an infection, **scars**, or other abnormalities underlying the vaginismus. If physiological causes for the condition are ruled out, the patient may be referred to a psychiatrist, psychologist, or sex therapist.

According to the *DSM-IV-TR*, the first criteria for a diagnosis of vaginismus are that **muscle spasms** in the outer third of the vagina are involuntary and are recurring or persistent. The symptoms must cause physical and/or emotional distress or, in particular, problems with relationships. The symptoms must exist independently of another mental disorder that could account for them.

Treatment

Traditional

As with most sexual disorders, there are many different treatments for vaginismus. Physical causes of vaginismus may require surgery or other treatment. Beyond that, treatment is aimed at reducing the **anxiety** and fear associated with penetration in order to weaken the reflexive tightening of vaginal muscles.

Desensitization techniques can, over time, enable a woman to relax her vaginal muscles and overcome the reflexive tightening of vaginismus. The woman begins by touching an area as close to her vaginal opening as possible without causing pain. Each day she touches a bit closer to the opening, becoming used to touching without pain. Once she can touch the tissues around the opening (the labia), she practices opening the vagina. Using a mirror to view her genitals, and bearing down, as if having a bowel movement, the opening is widened to make it more visible. Once she can touch the opening without pain, the woman inserts a finger past her hymen, pushing or bearing down to enlarge the opening. A small plastic dilator or cone is then inserted into the vagina, leaving it in place for 10–15 minutes. Once the vaginal muscles become used to the pressure, progressively larger inserts are used. Eventually, a dilator the size of a penis can be inserted comfortably. The woman's partner is then invited to insert the dilator. The couple then may attempt sexual intercourse. At first the woman may hold her partner's penis and insert it in her vagina. Some women are also more comfortable being on top during intercourse.

Desensitization procedures are somewhat controversial because they address the symptoms but not the cause of vaginismus. The exercises should be pursued under the direction of an experienced therapist or other healthcare provider. They should involve the sexual partner and gradually include intimate contact before culminating in sexual intercourse. Sometimes a male partner becomes overly cautious and reluctant to push and may lose his erection. In that case a phosphodiesterase inhibitor (sildenafil [Viagra], tadalafil [Cialis], or vardenafil [Levitra]) may be prescribed for the man.

Therapists also use **psychotherapy** or psychological techniques, couples or dual-sex therapy, **group therapy**, **hypnotherapy**, and/or behavioral therapies to treat vaginismus. Therapies should include information about sexual anatomy, physiology, the sexual response cycle, and common myths about sex. Treatment is usually extensive and multiple techniques are often used simultaneously.

Individual therapy often focuses on identifying and resolving underlying causes for vaginismus, such as childhood trauma or rape. When a woman has a trusting relationship with her therapist, insecurities or fears around sex resulting from factors such as parental attitudes or religious upbringing can often be revealed and successfully resolved.

Couples or dual-sex therapy is based on the concept that any sexual problems must be addressed by the couple, rather than the affected individual alone. The therapist will interact with the partners individually and as a couple. Addressing the couple's sexual history and any relationship problems may help to reveal and resolve the causes of vaginismus, especially when the disorder represents a nonverbal form of protest within a relationship. The couple is educated about the condition and taught various activities that may be helpful in overcoming the disorder.

Group therapy also can be effective for treating vaginismus. Couples or individuals who have the same or similar sexual disorders are brought together in a group. This setting can provide comfort and support for women or couples who are embarrassed or ashamed about their problem. Witnessing others discussing sex and sexual problems in an open and honest forum can encourage patients to become more open and honest themselves. Group therapy also exerts a certain amount of positive pressure and encouragement to open up and express oneself and to follow through with "homework," which may include masturbation or certain kinds of foreplay.

Hypnotherapy is effective for some patients with vaginismus. Hypnotherapy tends to focus on overcoming the condition itself, rather than resolving any underlying causes or conflicts. It often entails a number of sessions during which the patient and therapist define the goals of hypnotherapy. When the actual hypnosis occurs, suggestions are aimed at resolving underlying fears or concerns and alleviating symptoms. For example, the patient may be told that she can have intercourse without pain and that she will be able to overcome her muscle spasms. Problems that are causing the vaginismus may be explored under hypnosis and attempts made to reverse underlying feelings or fears.

Cognitive behavioral therapy (CBT) assumes that vaginismus is a learned behavior that can be unlearned. Behavioral therapy usually involves desensitization. Patients are exposed to situations that create a mild sense of psychological discomfort or anxiety. Once this mild anxiety is overcome, they are exposed to sexual situations that they find successively more threatening, until eventually coitus is achieved without difficulty.

Drugs

Infections underlying vaginismus can be treated with medications. A recent study found that injections

with botulinum neurotoxin type A was often effective in treating vaginismus in women with vulvar vestibulitis syndrome.

Alternative

Biofeedback may help teach a woman to control her vaginal muscles.

Home remedies

Specific exercises, including pelvic floor muscle contractions and relaxation called Kegel exercises, may help women control muscle contractions during sex.

Prognosis

Vaginismus is one of the most treatable sexual disorders, with a success rate of at least 63%. Because the causes of vaginismus vary, different treatments are successful with different women. In general a treatment plan that combines two or more therapeutic techniques supervised by a specialist in **sex therapy** has the greatest likelihood of success. Untreated vaginismus can lead to unsatisfying sexual relationships, tension, and emotional distress between partners.

Prevention

There are no known preventions for vaginismus; however, maintaining open and honest communication within a sexual relationship may help prevent the disorder. Seeking prompt treatment if vaginismus does occur can minimize problems.

Vaginitis *see* **Vulvovaginitis**

Vagotomy

Definition

Vagotomy is the surgical cutting of the vagus nerve to reduce acid secretion in the stomach.

Purpose

The vagus nerve splits into branches that go to different parts of the stomach. Stimulation from these branches causes the stomach to produce acid. Too much stomach acid leads to ulcers that may eventually bleed and create an emergency situation.

Vagotomy is performed when acid production in the stomach can not be reduced by other means. It is used when ulcers in the stomach and duodenum do not respond to medication and changes in diet. It is an appropriate surgery when there are ulcer complications, such as obstruction of digestive flow, bleeding, or perforation. The frequency with which elective vagotomy is performed has decreased since the 1990s as drugs have become increasingly effective in treating ulcers. However, the number of vagotomies performed in emergency situations has remained about the same.

Vagotomy is often performed in conjunction with other gastrointestinal surgery, such as partial removal of the stomach (antrectomy or subtotal **gastrectomy**). There are several types of vagotomies. Truncal

vagotomy severs the trunk of the vagus nerve as it enters the abdomen. Parietal cell or proximal gastric vagotomy leaves the trunk intact, but severs the branches that go to different parts of the stomach.

Precautions

Patients who receive vagotomies are most often seen in emergency situations where bleeding and perforated ulcers make it necessary to act immediately. As with any major surgery, people who use alcohol excessively, smoke, are obese, and are very young or very old are at higher risks for complications.

Description

Vagotomy is performed under **general anesthesia** by a surgeon in a hospital. The surgeon makes an incision in the abdomen and locates the vagus nerve. Either the trunk or the branches leading to the stomach are cut. Then the abdominal muscles are sewn back together, and the skin is closed with sutures.

Often, other gastrointestinal surgery is performed at the same time as the vagotomy. Part of the stomach may be removed, for instance. Vagotomy causes a decrease in peristalsis and a change in the emptying patterns of the stomach. To ease this, a **pyloroplasty** is often performed. This procedure widens the outlet from the stomach to the small intestine.

Preparation

A gastroscopy and x rays of the gastrointestinal system are performed as diagnostic procedures to determine the position and condition of the ulcer. Standard preoperative blood and urine tests are done. The patient should discuss with the anesthesiologist any medications or conditions that might affect the administration of anesthesia.

Aftercare

Patients who have had a vagotomy stay in the hospital for about seven days. For the first three or four days, nasogastric suctioning is required. A tube is inserted through the nose and into the stomach. The stomach contents are then suctioned out. Patients eat a clear liquid diet until the gastrointestinal tract is functioning again. When patients return to a regular diet, spicy and acidic food should be avoided.

It takes about six weeks to fully recover from the surgery. The sutures that close the skin can be removed in 7–10 days. Patients are encouraged to move around soon after the operation to prevent the formation of deep vein **blood clots**. **Pain** medication, stool softeners, and **antibiotics** may be prescribed following the operation.

KEY TERMS

Duodenum—The section of the small intestine immediately after the stomach.

Peristalsis—The rhythmic contractions that move material through the bowel.

Risks

As with all surgery, excessive bleeding and infection are possible complications. In addition, the emptying patterns of the stomach are changed. This can lead to dumping syndrome and **diarrhea**. Dumping syndrome is a condition where shortly after eating, the patient experiences **palpitations**, sweating, **nausea**, cramps, **vomiting**, and diarrhea.

Normal results

Normal recovery is expected for most patients. In about 10% of those who have vagotomy without stomach removal, ulcers recur. Between 2% and 3% of patients who have some portion of their stomach removed also have recurrent ulcers.

Valsalva maneuver

Definition

The Valsalva maneuver is performed by attempting to forcibly exhale while keeping the mouth and nose closed. It is used as a diagnostic tool to evaluate the condition of the heart and is sometimes done as a treatment to correct abnormal heart rhythms or relieve chest **pain**.

Purpose

The Valsalva maneuver is used with patients who have suspected heart abnormalities, often in conjunction with **echocardiography**. The maneuver is based on the fact that when a patient forcibly exhales against a closed nose and mouth while bearing down, as if having a bowel movement, specific changes occur in blood pressure and the rate and volume of blood returning to the heart.

Comparing the changes in a diseased heart to those expected in a normal heart gives clues to the type and location of heart damage. In addition, when a doctor listens to the chest with a stethoscope during the Valsalva maneuver, characteristic heart sounds are heard. Variations in these sounds can indicate the type of abnormality present in the heart. A 2004 study found that blood pressure response to the Valsalva maneuver could predict mortality in elderly patients with congestive **heart failure**. This could prove to be a new noninvasive way to help determine how long elderly patients with congestive heart failure are expected to live.

The Valsalva maneuver also corrects some rapid heartbeats originating in the atria. When the maneuver is done correctly, blood pressure rises. This forces the heart to respond by correcting its rhythm and beating more slowly. On rare occasions, the Valsalva maneuver can be used to diminish chest pain in patients with mild coronary disease.

Unrelated to any evaluation of the heart, the Valsalva maneuver also is taught to patients with **multiple sclerosis** who are unable to fully empty the bladder (flaccid bladder). It sometimes is used in sexual therapy to help men avoid **premature ejaculation**.

Precautions

The Valsalva maneuver should not be performed by patients who have severe **coronary artery disease**, have experienced recent **heart attack**, or have a moderate to severe reduction in blood volume.

Description

When performed formally, the patient is asked to blow against an aneroid pressure measuring device (manometer) and maintain a pressure of 40 millimeters of mercury (mm Hg) for 30 seconds. Less formally, the patient may be asked to bear down, as if having a bowel movement. During this 30 second period, a recording is made of the changes in blood pressure and murmurs of the heart.

KEY TERMS

Atria—The heart has four chambers. The right and left atria are at the top of the heart and receive returning blood from the veins. The right and left ventricles are at the bottom of the heart and act as the body's main pumps.

Echocardiography—An ultrasound test that shows the size, shape, and movement of the heart.

Preparation

The patient may be connected to a heart monitor and echocardiograph or the physician may simply use a stethoscope to monitor the heart. Sometimes an indwelling needle is inserted for accurate pressure measurements, depending on whether the procedure is being done for corrective or diagnostic purposes.

Aftercare

When this procedure is done to regulate irregular heart rhythms, the patient usually remains on a heart monitor to evaluate heartbeat.

Risks

The patient may feel dizzy or faint during the procedure, but serious consequences are rare. There is a risk that the Valsalva maneuver can cause **blood clots** to detach, bleeding, and abnormal rhythms originating in the ventricle. It can also cause cardiac arrest. Consequently, the procedure is usually performed in a setting where emergency equipment is accessible.

Normal results

There are four characteristic changes or phases in a normal heart's response to the Valsalva maneuver. An abnormality in any of these phases indicates a cardiovascular abnormality.

Valvular heart disease

Definition

Valvular heart disease refers to several disorders and diseases of the heart valves, which are the tissue flaps that regulate the flow of blood through the chambers of the heart.

Description

The human heart consists of four chambers—two upper chambers (the atria) and two lower chambers (the ventricles)—that are responsible for pumping blood. The heart valves are like one-way doors, which open and close with each beat of the heart, controlling the blood flow from one chamber to the next. Each of these valves is made up of a few thin folds of tissue. When functioning correctly, they keep blood from flowing backward into a chamber when closed.

The four valves function in the following manner:

- The mitral valve is located between the left atrium and the left ventricle. It is the only valve with two flaps, or cusps.
- The tricuspid valve is located on the right side of the heart, between the right atrium and right ventricle. It is made up of three cusps, each a different size.
- The aortic valve is located on the left side of the heart and opens to allow blood to leave the heart from the left ventricle into the aorta, which is the main artery of the body. It closes to prevent blood from flowing back into the left ventricle.
- The pulmonary valve is situated on the right side of the heart, between the right ventricle and pulmonary artery. It allows blood to exit the heart and enter the lungs via the pulmonary artery. It closes to prevent blood from flowing back into the right ventricle.

Patients with valvular heart disease have a malfunction of one or more of these valves. There are several types of valvular heart diseases with distinct symptoms and treatments. These are:

- mitral valve prolapse (displacement)
- mitral valve insufficiency (regurgitation)
- mitral valve stenosis (narrowing)
- aortic valve insufficiency
- aortic valve stenosis
- tricuspid valve insufficiency
- tricuspid valve stenosis
- pulmonic stenosis
- pulmonic insufficiency

Certain types of heart disease can lead to one of the specific conditions listed above. These include **rheumatic fever** and infective inflammation of the heart (**endocarditis**). Multivalvular heart disease refers to a condition involving more than one of the heart valves.

Causes and symptoms

Problems with heart valves may occur as a result of infection, degeneration, or congenital abnormality. The most common infections are rheumatic **fever** and infective endocarditis.

Rheumatic fever

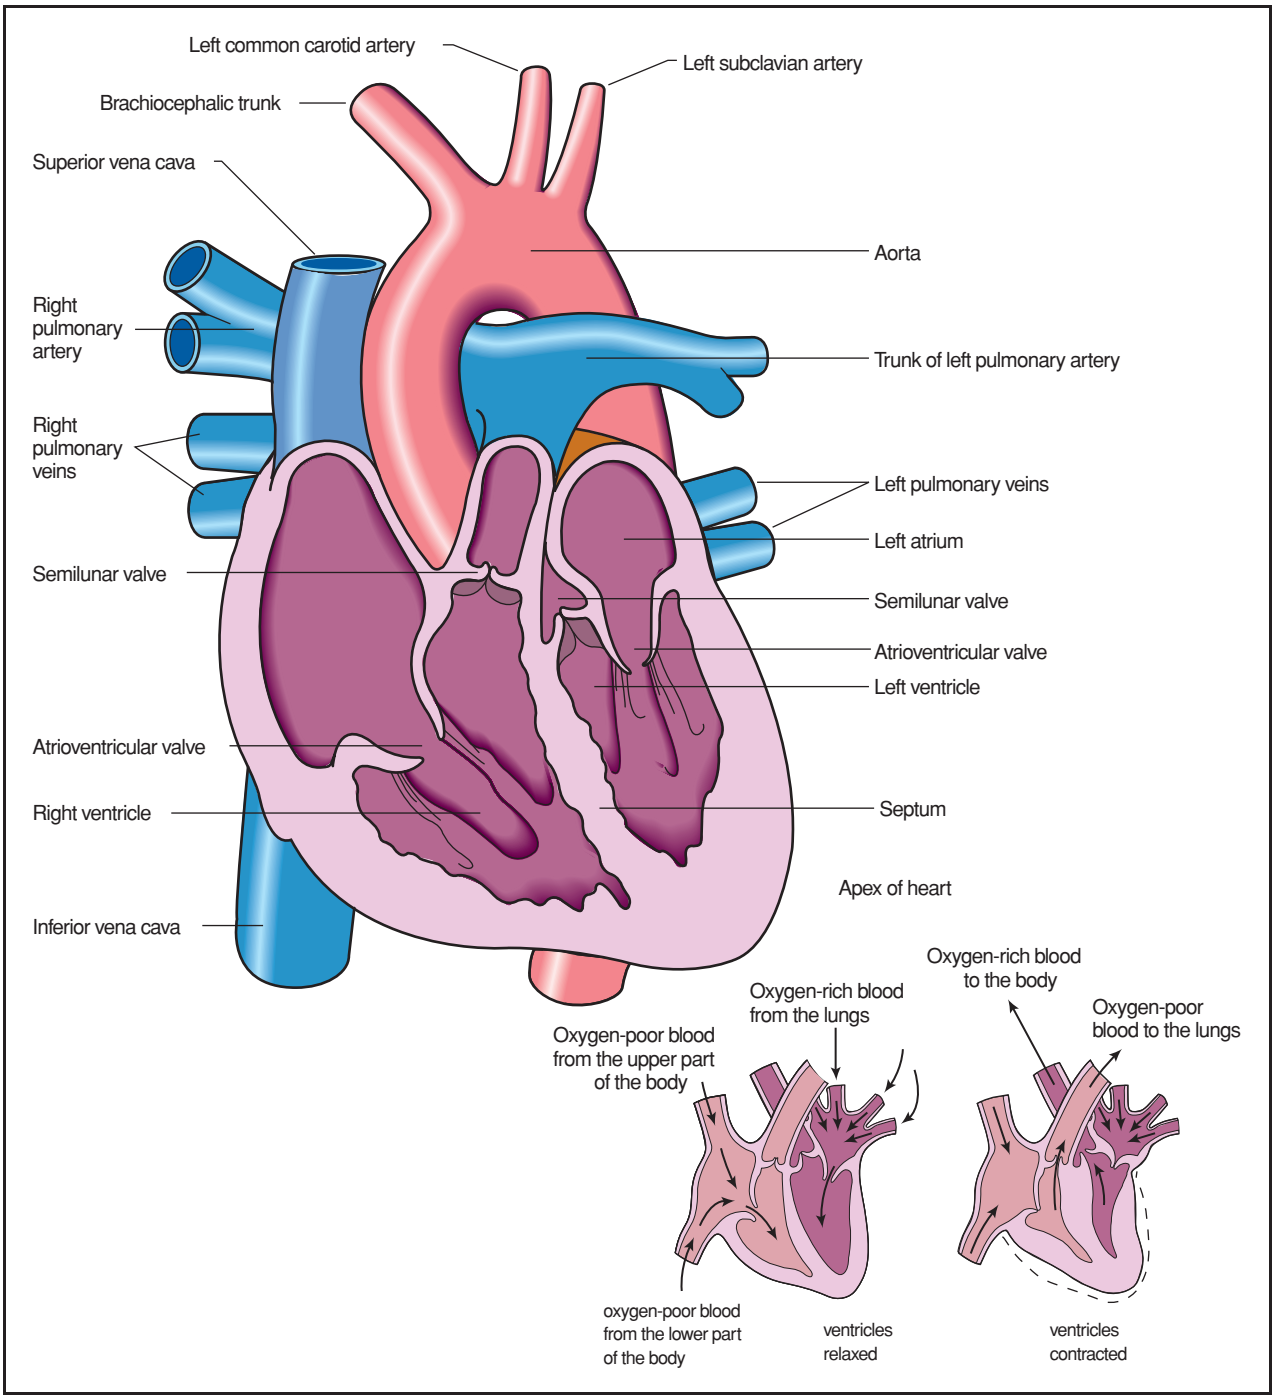
Rheumatic fever is a condition that results from the body's immune response to certain types of streptococcal bacteria. It occurs rarely. When it occurs, it is most often in children who have had **strep throat** that was not completely treated. The symptoms of rheumatic fever include heart inflammation, uncontrolled movement of face and limbs, arthritis that moves from joint to joint, **shortness of breath**, weakness, and either lumps under the skin or raised red patches on the skin. The most common valvular heart diseases to result from rheumatic fever are mitral stenosis, tricuspid stenosis, aortic insufficiency, aortic stenosis, multivalvular involvement, and less commonly, pulmonic stenosis. Chronic rheumatic heart disease can result from one occurrence or from repeated attacks. It is not as common as it once was in the United States, but still occurs frequently in developing countries.

Infective endocarditis

Infective endocarditis is an infection and inflammation of the inner layer, or membrane, of heart tissue (endocardium). Most people with a healthy, normal heart are not at significant risk for contracting infective endocarditis. However, people who have had rheumatic fever, with its resulting scarring, or a congenital cause of heart malformation, may contract this disease when certain bacteria enter the bloodstream and become lodged in the heart. In particular, dental surgery or any surgery involving the mouth, bladder, prostate, or female pelvic organs increases risk for this infection. The disease also may occur in drug addicts who inject their veins using unsterilized needles, even if they have normal heart valves. Symptoms of infective endocarditis include fever, a new or changing heart murmur, and abnormal loss of appetite or **fatigue**.

The use of appetite suppressants

In 1997 the manufacturers of fen-phen, the abbreviation for a combination of the two weight-loss drugs



Anatomy of the human heart. The illustration at the bottom right shows how the right and left ventricles contract and relax when blood is pumped through the heart. *(Illustration by Hans & Cassady, Inc. Reproduced by permission of Gale, a part of Cengage Learning.)*

fenfluramine and phentermine, withdrew the supplements from the market. Preliminary research showed that they caused heart valve problems in some patients. Physicians were concerned that this drug combination could affect the heart valves because the drugs alter the metabolism of serotonin in the body. Serotonin is a natural substance found in the brain and intestines that can affect blood vessels. Until the issue could be studied more, physicians recommended that patients taper off the drugs, finally stopping them

altogether. Eventually, the company reached a $3.75 billion settlement of most lawsuits by former users of the diet drugs.

Other valvular heart disease

The mitral and aortic valves may also be affected by deposits of **calcium** in the heart that occurs with **aging**. This can lead to thickening and leakage of heart valves. Heart attacks also can damage the mitral valve structures. Additionally, certain connective tissue disorders can adversely affect the heart valves, for example, Marfan's syndrome and myxomatous degeneration.

Diagnosis

Specific types of valvular heart disease are diagnosed using **electrocardiography** (EKG), **echocardiography**, certain x-ray studies, and/or **cardiac catheterization**. An EKG provides a record of electrical changes in the heart muscle during the heartbeat. Echocardiography uses sound waves to make images of the heart. These images can show if there are any abnormalities of the heart valves. Cardiac catheterization is a procedure in which a small tube (called a catheter) is inserted into an artery and passed into the heart. It is used to measure pressure in the heart and the amount of blood pumped by the heart.

Rheumatic fever

Rheumatic fever may be suspected when a recent throat infection has occurred and other major or minor symptoms appear, such as joint ache, abnormal EKG, or a blood test indicating heart inflammation. **Heart murmurs** may be detected from routine examination.

Infective endocarditis

A diagnosis of infective endocarditis can be obtained through patient history, EKG, ultrasound, or cardiac catheterization. Patients who have developed the disease rapidly may report fever, fatigue, night sweats, chills, and joint inflammation. Those whose disease has developed more slowly will show signs of rapid heart rate, an enlarged spleen, various skin colors or spots, and heart murmur. The physician may order blood tests to determine what is causing the infection.

Appetite suppressants

People with a history of using appetite suppressants may be sent for EKGs or further testing if any of the symptoms of valvular heart disease, such as swelling, considerable fatigue, or shortness of breath occur.

Treatment

The treatment of specific valvular heart diseases will vary, depending on the valve involved and the extent of damage or malfunction. Some patients will not require treatment and many will be treated with medication. Sometimes, patients need surgery. If multivalvular disease is suspected or involved, different valves may be evaluated during surgery on one of the affected valves. Women with heart valve disease who want to become pregnant should receive a thorough check-up and see a cardiologist regularly throughout their **pregnancy**.

Rheumatic fever

Patients with rheumatic fever will be treated with **antibiotics** to eliminate streptococcal organisms that may still remain in the heart. Patients may receive antibiotics to prevent further infection, and inflammation may be treated with **aspirin** or cortisone-like drugs.

Infective endocarditis

Physicians will use the appropriate antibiotic or some combination of antibiotics to treat infective endocarditis, depending on the type of bacterium that caused the disease. Severe cases of this disease may be corrected by valve replacement surgery.

Appetite suppressants

The role of appetite suppressants (fen-phen) in valvular heart disease has been under study. Many of the people who suffered complications of the diet drugs experienced regurgitation. However, some 2001 studies found that these valve problems often did not worsen or even improved after a period of time after the patients stopped taking fen-phen.

Prognosis

The prognosis for patients with valvular heart disease varies depending on the underlying cause, age and health of the patient, and the degree of valvular damage or involvement.

Rheumatic fever

Patients with rheumatic heart disease face a lifetime of caution over contact with the same bacterium that caused the disease. Since it can cause inflammation of one or more organs or joints, complications

KEY TERMS

Congenital—Used to describe a condition or defect present at birth.

Stenosis—An abnormal valve condition which is characterized by tightening or narrowing of the opening.

Streptococcal (*Streptococcus*)—*Streptococcus* is a bacterium that causes infection in people. Its most commonly known strain causes the infection strep throat.

Throat culture—A test for strep throat that involves swabbing the back of the throat and sending the swab to a laboratory, which will determine whether bacteria is present.

can occur. The inflammation of the heart may subside without side effects. Permanent scarring of one or more heart valves is a possibility and may require surgery to repair or replace damaged valves. In severe cases, rheumatic fever can lead to **death** from **heart failure**.

Infective endocarditis

The prognosis for patients with infective endocarditis depends on the underlying heart disease and resulting complications. If the disease further damages heart valves, symptoms may occur for years after initial treatment. Sometimes, endocarditis can result in heart or renal failure. If untreated, it can be fatal.

Appetite suppressants

Since it is believed that different valves may be affected, treatment for those taking these drugs most likely follows a similar course as that for the specific valvular disease.

Prevention

Certain measures can be taken to prevent some valvular disease. However, once valvular heart disease that results from congenital abnormality occurs, it may not be prevented. Steps can be taken to prevent further complications.

Rheumatic fever

The best prevention for rheumatic fever is prompt and thorough treatment of any suspected streptococcal infection, particularly strep throat in children. A physician should check any **sore throat** with fever that persists for more than 24 hours. The physician will probably order a **throat culture**. Completion of the antibiotic treatment even after symptoms diminish is important to be certain the infection is eliminated.

Infective endocarditis

Anyone who was born with a defective heart valve, those with artificial (prosthetic) valves, or those who have had a valve scarred by rheumatic fever, should use prescribed antibiotics by mouth before and after a dental procedure. These patients also may need to receive injected antibiotics prior to procedures involving the bladder, prostate, and pelvic organs.

Appetite suppressants

The drug associated with valvular heart disease, fen-phen, was removed from the market, so as long as people avoid obtaining this appetite suppression combination, they can prevent its negative effects.

Varicose veins

Definition

Varicose veins are dilated, tortuous, elongated superficial veins that are usually seen in the legs.

Description

Varicose veins, also called varicosities, are seen most often in the legs, although they can be found in other parts of the body. Most often, they appear as lumpy, winding vessels just below the surface of the skin. There are three types of veins, superficial veins that are just beneath the surface of the skin, deep veins that are large blood vessels found deep inside muscles, and perforator veins that connect the superficial veins to the deep veins. The superficial veins are the blood vessels most often affected by varicose veins and are the veins seen by eye when the varicose condition has developed.

The inside wall of veins has valves that open and close in response to the blood flow. When the left ventricle of the heart pushes blood out into the aorta, it produces the high pressure pulse of the heartbeat and pushes blood throughout the body. Between heartbeats, there is a period of low blood pressure. During the low pressure period, blood in the veins is affected by gravity and wants to flow downward. The valves in the veins prevent this from happening.

Varicose veins on a man's leg. *(Custom Medical Stock Photo, Inc. Reproduced by permission.)*

Varicose veins start when one or more valves fail to close. The blood pressure in that section of vein increases, causing additional valves to fail. This allows blood to pool and stretch the veins, further weakening the walls of the veins. The walls of the affected veins lose their elasticity in response to increased blood pressure. As the vessels weaken, more and more valves are unable to close properly. The veins become larger and wider over time and begin to appear as lumpy, winding chains underneath the skin. Varicose veins can develop in the deep veins also. Varicose veins in the superficial veins are called primary varicosities, while varicose veins in the deep veins are called secondary varicosities.

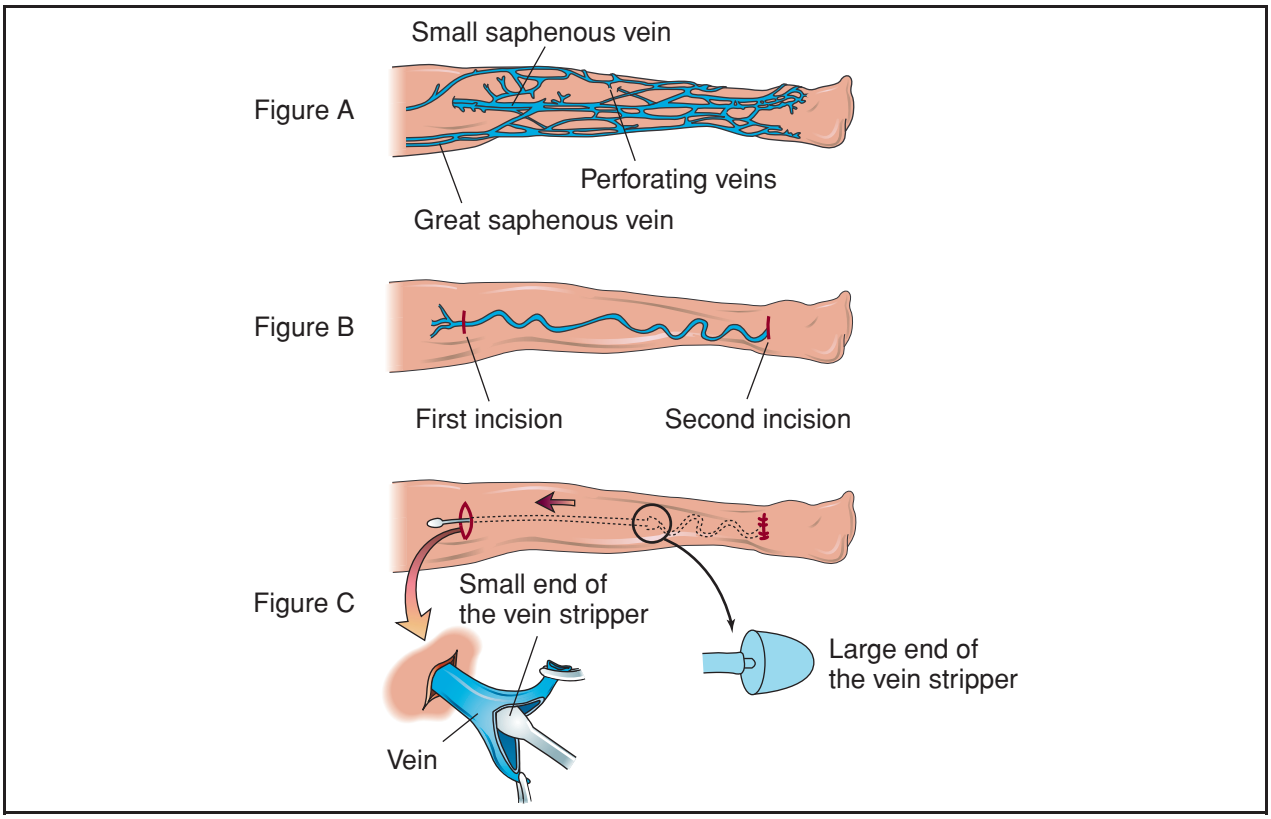
Causes and symptoms

The predisposing causes of varicose veins are multiple, and lifestyle and hormonal factors play a role. Some families seem to have a higher incidence of varicose veins, indicating that there may be a genetic component to this disease. Varicose veins are progressive; as one section of the veins weakens, it causes increased pressure on adjacent sections of veins. These sections often develop varicosities. Varicose veins can appear following **pregnancy**, **thrombophlebitis**, congenital blood vessel weakness, or **obesity**, but is not limited to these conditions. **Edema** of the surrounding tissue, ankles, and calves, is not usually a complication of primary (superficial) varicose veins and, when seen, usually indicates that the deep veins may have varicosities or clots.

Varicose veins are a common problem; approximately 15% of the adult population in the United States have varicose veins. Women have a much higher incidence of this disease than men. The symptoms can include aching, **pain**, itchiness, or burning sensations, especially when standing. In some cases, with chronically bad veins, there may be a brownish discoloration of the skin or ulcers (open sores) near the ankles. A condition that is frequently associated with varicose veins is spider-burst veins. Spider-burst veins are very small veins that are enlarged. They may be caused by back-pressure from varicose veins, but can be caused by other factors. They are frequently associated with pregnancy and there may be hormonal factors associated with their development. They are primarily of cosmetic concern and do not present any medical concerns.

Diagnosis

Varicose veins can usually be seen. In cases where varicose veins are suspected, but can not be seen, a physician may frequently detect them by palpation (pressing with the fingers). X rays or ultrasound tests



Varicose veins may be surgically removed from the body when they are causing pain and when hemorrhaging or recurrent thrombosis appear. Surgery involves making an incision through the skin at both ends of the section of vein being removed (figure B). A flexible wire is inserted through one end and extended to the other. The wire is then withdrawn, pulling the vein out with it (figure C). *(Illustration by Electronic Illustrators Group. Reproduced by permission of Gale, a part of Cengage Learning.)*

can detect varicose veins in the deep and perforator veins and rule out **blood clots** in the deep veins.

Treatment

There is no cure for varicose veins. Treatment falls into two classes; relief of symptoms and removal of the affected veins. Symptom relief includes such measures as wearing support stockings, which compress the veins and hold them in place. This keeps the veins from stretching and limits pain. Other measures are sitting down, using a footstool when sitting, avoiding standing for long periods of time, and raising the legs whenever possible. These measures work by reducing the blood pressure in leg veins. Prolonged standing allows the blood to collect under high pressure in the varicose veins. **Exercise**, such as walking, biking, and swimming, is beneficial. When the legs are active, the leg muscles help pump the blood in the veins. This limits the amount of blood that collects in the varicose veins and reduces some of the symptoms. These measures reduce symptoms, but do not stop the disease.

Surgery is used to remove varicose veins from the body. It is recommended for varicose veins that are causing pain or are very unsightly and when hemorrhaging or recurrent thrombosis appear. Surgery involves making an incision through the skin at both ends of the section of vein being removed. A flexible wire is inserted through one end and extended to the other. The wire is then withdrawn, pulling the vein out with it. This is called "stripping" and is the most common method to remove superficial varicose veins. As long as the deeper veins are still functioning properly, a person can live without some of the superficial veins. Because of this, stripped varicose veins are not replaced.

Injection therapy is an alternate therapy used to seal varicose veins. This prevents blood from entering the sealed sections of the vein. The veins remain in the body, but no longer carry blood. This procedure can be performed on an outpatient basis and does not require anesthesia. It is frequently used if people develop more varicose veins after surgery to remove the larger varicose veins and to seal spider-burst veins

KEY TERMS

Congenital—Existing at or before birth; a condition that developed while the fetus was in utero or as a consequence of the birth process.

Edema—Swelling caused by a collection of fluid in a tissue or body cavity.

Hemorrhage—Bleeding from blood vessels.

Palpation—The process of examining a patient by touch.

for people concerned about cosmetic appearance. Injection therapy is also called sclerotherapy. At one time, a method of injection therapy was used that did not have a good success rate. Veins did not seal properly and blood clots formed. Modern injection therapy is improved and has a much higher success rate.

Prognosis

Untreated varicose veins become increasingly large and more obvious with time. Surgical stripping of varicose veins is successful for most patients. Most do not develop new, large varicose veins following surgery. Surgery does not decrease a person's tendency to develop varicose veins. Varicose veins may develop in other locations after stripping.

Variola *see* **Smallpox**

Vascular disease

Definition

Vascular disease is a general term for disease that occurs in the arteries and veins. There are many specific types of vascular disease.

Demographics

Vascular disease is common, especially in people over age 50. The exact number of people with vascular disease is difficult to estimate, as many vascular diseases show no symptoms until they reach an advanced stage. Estimates suggest that about 37% of Americans (over 80 million individuals) have cardiovascular disease (disease of either the heart or vascular system) and about 795,000 Americans have strokes each year. Vascular disease is more common in men than in women and appears in men at an earlier age. Researchers believe that the female hormone estrogen provides a protective effect until women reach the age of **menopause** at about age 50.

Internationally, vascular disease is highest in regions where people eat a Western diet high in animal fats and calories and low in fiber (e.g., Northern Europe). In cultures in Africa where the diet is low in animal products, low in calories, and high in whole grains, the prevalence of vascular disease is low.

Description

The vascular system is composed of arteries and veins. Arteries carry oxygen-rich blood away from the heart, while veins return oxygen-depleted blood to the heart. Vascular disease can occur in either arteries or veins, although vascular disease in arteries is more common.

Arteriosclerosis and **atherosclerosis** are the most common causes of vascular disease. Arteriosclerosis is commonly called "hardening of the arteries." The large and medium-sized arteries of the body have elastic, muscular walls. Whenever the heart contracts and pushes blood into the arteries, the walls of the artery expand slightly to accommodate the increased pressure of the blood. However, over many years, too much pressure can cause the artery walls to thicken and harden, losing their elasticity. This loss of elasticity is called arteriosclerosis.

Atherosclerosis is the build-up of plaque on the inside of the artery walls. Arterial plaque (different from dental plaque that builds up on teeth) is made up of fats, cholesterol, **calcium**, and bits of dead cells. Plaque can restrict the flow of blood. If blood flow is restricted, the heart must work harder (exert more pressure) to push blood through the artery and blood pressure rises. Plaque also can break off, causing damage to the artery wall. A blood clot may form where this happens. Bits of plaque and **blood clots** that form an **embolism** and travel through the vascular system with the potential to block a smaller artery and restrict or shut off the blood supply flowing through that artery. If blood supply to the heart is shut off, the individual has a **heart attack**. If blood supply is shut off in the internal carotid artery going to the brain or in any of the small vessels in the brain, the individual

has a **stroke**. If the brain blockage is brief and resolves on its own with minimal damage, the incident is called a **transient ischemic attack** (TIA). Blood vessels in other parts of the body also may be blocked, with blockage most common in the blood vessels in the legs. Arteriosclerosis and atherosclerosis most often occur together, and these words commonly are used interchangeably to indicate the presence of vascular disease.

Arteriosclerosis and atherosclerosis can lead to the following types of vascular disease. For greater detail, consult the entries for each specific disease.

- Hypertension (high blood pressure) because the heart must use more force to pump blood through inflexible arteries and past obstructions in the arteries.
- Coronary artery disease (CAD) when the coronary arteries supplying the heart are narrowed.
- Cerebrovascular disease, carotid artery disease, or stroke, when a blood vessel to the brain is narrowed or blocked.
- Peripheral artery disease (PAD) also called peripheral vascular disease (PDV), when blood vessels in other parts of the body, usually the legs, are narrowed or blocked. This is most common in people with diabetes.
- Renovascular disease when arteries to the kidney are narrowed.
- Peripheral aneurysms, which often occur in the abdomen or behind the knee. Aneurysms are weak spots in the wall of an artery that bulge out and can burst. They may form where plaque breaks off the artery wall.

Other types of vascular disease that are not directly related to atherosclerosis or arteriosclerosis include:

- Deep vein thrombosis develops from prolonged periods of inactivity that reduce circulation and allow blood to pool and clots to form in the interior (deep) veins of the legs.
- Pulmonary embolism occurs when a blood clot breaks off and travels to the artery supplying the lungs. Pulmonary embolisms that completely block the artery to the lung are fatal.
- Chronic venous insufficiency occurs when a blood clot prevents enough blood from flowing back to the heart.
- Thoracic outlet syndrome (TOS) can be caused by compression of a vein or artery going to the arm. Venous compression often is caused by repetitive, energetic use of the arm (e.g., baseball pitcher) and artery compression often occurs in individuals who were born with a small extra rib. Nerves can also be compressed in TOS.
- Certain disorders, such as thrombocythemia or polycythemia vera, cause blood to clot too easily, increasing the risk of embolism formation.

Risk factors

Although there are a number of different vascular diseases, most have risk factors in common. An increased risk of developing vascular disease occurs in individuals who:

- are obese
- smoke tobacco
- have high blood pressure
- have high cholesterol and triglyceride levels
- get little exercise
- eat a diet high in saturated fats and low in fiber
- have either type 1 or type 2 diabetes, especially if poorly controlled
- have a family history of heart or vascular disease
- experience prolonged immobility, such as during a hospital stay after surgery

Causes and symptoms

Poor diet resulting in high levels of cholesterol and fats in the blood, lack of **exercise**, **aging**, uncontrolled **hypertension**, and uncontrolled diabetes lead to the development of atherosclerosis and arteriosclerosis. These, in turn, cause other vascular diseases. Some vascular problems are have a hereditary component (e.g., TOS, blood clotting diseases).

Atherosclerosis and arteriosclerosis develop gradually with no symptoms until the artery is so rigid and narrow that not enough blood can flow through it to meet the needs of the tissue it supplies. At this point, **pain** is the most common symptom. Clogged coronary arteries can cause chest pain (**angina**) and complete blockage causes a heart attack (myocardial infarction). Clogged arteries supplying the brain can lead to diminished mental function. Complete blockage of the blood supply can result in sudden **numbness** and weakness in the face, arm, or leg. Speech and coordination may be affected. If these events are brief and there is no lasting damage, the individual is said to have had a transient ischemic attack or TIA, or "warning stroke." If damage is permanent, the individual is said to have had a stroke or cerebrovascular accident (CVA). **Peripheral vascular disease** usually results in pain. If blockage occurs in the legs, the individual will have pain when walking and possible swelling. Sores on the legs and feet will be slow to heal. Blockage of

KEY TERMS

Aneurysm—An abnormal bulge of an artery that can rupture leading to hemorrhage.

Angiogram—An x-ray (radiographic) study of the blood vessels. An angiogram uses a radiopaque substance, or contrast medium, to make the blood vessels visible under x ray.

Angioplasty—A technique used for treating blocked coronary arteries by inserting a catheter with a tiny balloon at the tip into the artery and then inflating it.

Arteriosclerosis—A chronic condition characterized by thickening and hardening of the arteries and the build-up of plaque on the arterial walls. Arteriosclerosis can slow or impair blood circulation.

Atherosclerosis—A chronic condition characterized by of plaque formed by on the arterial walls. Atherosclerosis can slow or impair blood circulation.

Balloon angioplasty—A surgical procedure is done to reopen a partially blocked artery so that blood can flow through it again at a normal rate. A tiny tube (catheter) is threaded through blood vessels to the point of the blockage. The catheter contains a balloon that is then expanded to stretch and open the artery.

Carotid artery—An artery located in the neck. There are two on each side of the neck. The internal carotid artery carries blood to the brain while the external carotid artery carries blood to skin and muscles of the face.

Cholesterol—A waxy substance made by the liver and also acquired through diet. High levels in the blood may increase the risk of cardiovascular disease.

Coronary arteries—These are the first arteries to branch off the aorta (the large artery leaving the heart). The coronary arteries surround the heart like a crown, coming out of the aorta, arching down over the top of the heart, dividing into two branches, and taking oxygen-rich blood to the heart muscle. Blockage of these arteries can cause insufficient blood flow to the heart or a heart attack.

Coronary artery disease (CAD)—Also called atherosclerosis, it is a build-up of fatty matter and debris in the coronary artery wall that causes narrowing of the artery.

Electrocardiogram (ECG, EKG)—A test that records the electrical activity of the heart using small electrode patches attached to the skin on the chest.

Embolism—A blood clot, air bubble, or clot of foreign material that travels and blocks the flow of blood in an artery. When blood supply to a tissue or organ is blocked by an embolism, infarction (death of the tissue the artery feeds) occurs. Without immediate and appropriate treatment, an embolism can be fatal.

Stent—A device made of expandable, metal mesh that is placed (by using a balloon catheter) at the site of a narrowing artery; the stent stays in place to keep the artery open.

Stress test—A test that involves an electrocardiogram during rest and exercise to determine how the heart responds to stress.

Stroke—Irreversible damage to the brain caused by insufficient blood flow to the brain as the result of a blocked artery. Damage can include loss of speech or vision, paralysis, cognitive impairment, and death.

Triglycerides—A type of fat found in the blood. High levels of triglycerides can increase the risk of coronary artery disease.

Type 1 diabetes—A chronic immune system disorder in which the pancreas does not produce sufficient amounts of insulin, a hormone that enables cells to use glucose for energy. Also called juvenile diabetes, it must be treated with insulin injections.

Type 2 diabetes—Formerly called adult-onset diabetes. In this form of diabetes, the pancreas either does not make enough insulin or cells become insulin resistant and do not use insulin efficiently.

Ultrasound—A technique that uses high-frequency sound waves to create a visual image (a sonogram) of soft tissues.

the arteries leading to the penis can cause **erectile dysfunction**.

Diagnosis

Diagnosis of vascular disease may occur during a routine **physical examination** or after the individual complains of symptoms.

Examination

Diagnosis begins with a complete physical examination and medical history. The doctor may notice abnormally high blood pressure or a week pulse below the area of a blockage in an artery. By listening to the arteries in the neck, the doctor may be able to hear an abnormal whooshing sounds (bruits). These

sounds are caused by blood flowing around a blockage. The doctor also will look for signs of poor wound healing in the arms, legs, and feet, especially if the patient has diabetes.

Tests

Blood tests are done as part of a routine physical. Cholesterol, triglyceride, and blood sugar (blood glucose) levels will be checked. A urine test will look for protein in the urine which indicated a problem with kidney function.

If blockage of an artery is suspected, a series of non-invasive tests can be performed to located the blockage and estimate its size. These include:

- Doppler ultrasound. This is the standard diagnostic test for blood clots in the vascular system. An ultrasound wand applied over the area of the suspected blockage uses high-frequency sound waves to measure the speed at which the blood moves through the artery. Movement at an abnormal speed indicates a blockage.
- Ankle-brachial index. This is a test to determine if there is a narrowing of arteries in the legs or feet. First, blood pressure is taken in the normal way in the arm. Next, blood pressure is taken in the ankle. In a healthy person, the systolic pressure (the top number in a blood pressure reading) in both places will be approximately equal. If systolic pressure is lower in the ankle reading, this suggests the individual has PAD in the leg.
- Electrocardiogram (ECG). In this test, electrodes are placed on the chest to measure the electrical activity of the heart. If an ECG is done while walking on a treadmill, it is called a stress test. The results of this test can be used to help determine the health of the arteries supplying blood to the heart.

Procedures

When an artery blockage has been found, the doctor may perform an angiogram to determine its exact size and location. A special dye is injected into the arteries that make them visible on x ray images. From this, the doctor can pinpoint the location and size of the blockage(s). This test often is done before surgery to help guide the surgical procedure.

Treatment

Mild to moderate vascular disease usually is treated with a combination of lifestyle changes and drug therapy. If this fails, or if vascular disease is severe, surgery may be required.

Home remedies and lifestyle changes

An important first-line treatment for mild to moderate vascular disease involves lifestyle changes. These can be very effective. They include:

- losing weight if necessary and maintaining a healthy weight
- stopping smoking
- avoiding alcohol or consuming alcohol in moderation
- exercising moderately but regularly (five days a week)
- eating a diet low in animal fats and sweets and high in fresh fruits, vegetables, and fiber
- controlling high blood pressure through salt (sodium) restriction, exercise, and medications as necessary
- controlling diabetes through exercise, diet, and medication as necessary by monitoring blood glucose levels regularly

Drugs

When lifestyle changes are not enough to control vascular disease, drug therapy may be added to the program. These drugs normally will be taken long term and should not be stopped without consulting a doctor. Drugs may include:

- cholesterol-lowering drugs such as simvastin (Zocor) or atorvastatin (Lipitor)
- anti-platelet drugs such as aspirin or cloplidgrel (Plavix) to reduce the chance of platelets forming clumps in the blood
- anticoagulant drugs such as warfarin (Coumadin)to keep blood from clotting
- drugs to lower blood pressure (antihypertensive drugs)

Surgery

When drugs and lifestyle changes are not adequate or if blood vessel blockage is severe, surgical procedures may be used to open the blood vessel. These include:

- Balloon angioplasty. In this procedure, a thin wire with a deflated balloon at the tip is moved through an artery until it reaches the blockage. The balloon is then inflated so that the obstructing plaque is pressed against the artery wall and the vessel is made wider. Often a short mesh tube called a stent is placed at the site of the blockage to keep the blood vessel open.
- Endartectomy or atherectomy. These are surgical procedures to ream out blood vessels. This is sometimes called "Rotorooter surgery." Endartectomy is often performed on the carotid artery.

- Bypass surgery. A section of blocked vessel is surgically removed and replaced with blood vessel taken from elsewhere in the body.
- Thrombolytic therapy. This uses a drug that breaks up blood clots. The drug is surgically delivered to the spot in the artery where the clot exists.

Prognosis

The progression of vascular disease often is silent and gradual until a dramatic event such as a stroke or heart attack occurs. When recognized early, vascular disease is highly treatable through lifestyle changes and drug therapy. When recognized late, surgery may be required. If unrecognized, vascular disease can be fatal. Cardiovascular disease accounts for about 35% of all deaths in the United States.

Prevention

Prevention is the same as the lifestyle changes listed under home remedies—healthy diet, exercise, avoiding **smoking**, maintaining a healthy weight and controlling blood pressure and diabetes. Prevention needs to begin at as early an age as possible because vascular disease normally shows no symptoms until it is advanced. However, making these changes, even after vascular disease has developed can reverse or slow its progression.

Vascular surgery

Definition

Vascular surgery is the treatment of surgery on diagnosed patients with diseases of the arterial, venous, and lymphatic systems (excluding the intracranial and coronary arteries).

Purpose

Vascular surgery is indicated when a patient has **vascular disease** that cannot be treated by less invasive, non-surgical treatments. The purpose of vascular surgery is to treat vascular diseases, which are diseases of the arteries and veins. Arterial disease is a condition in which **blood clots**, arteriosclerosis, and other vascular conditions occur in the arteries. Venous disease involves problems that occur in the veins. Some vascular conditions occur only in arteries, others occur only in the veins, and some affect both veins and arteries.

Demographics

As people age, vascular diseases are very common. Since they rarely cause symptoms in the early stages, many people do not realize that they suffer from these diseases. A large percentage of the 10 million people in the United States who may have **peripheral vascular disease** (PVD) are males. In the majority of cases, the blockage is caused by one or more blood clots that travel to the lungs from another part of the body. Factors that increase the chances of vascular disease include:

- increasing age (which results in a loss of elasticity in the veins and their valves)
- a family history of heart or vascular disease
- illness or injury
- pregnancy
- prolonged periods of inactivity sitting, standing, or bed rest
- smoking

KEY TERMS

Ankle-brachial index (ABI) test—A means of checking the blood pressure in the arms and ankles using a regular blood pressure cuff and a special ultrasound stethoscope (Doppler). The pressure in the ankle is compared to the pressure in the arm.

Aorta—A large, elastic artery beginning at the upper part of the left ventricle of the heart that becomes the main trunk of the arterial system.

Aortic aneurysms—Occurs when an area in the aorta (the main artery of the heart) is weakened and bulges like a balloon.

Arteriogram—A test to check the blood pressure at several points in the leg by using a blood pressure cuff and a Doppler. The patient is then asked to walk on a treadmill, after which the ankle pressure is taken again to determine if the pressure decreased after walking.

Abdominal aortic aneurysm—Occurs when an area in the aorta (the main artery of the heart) is weakened and bulges like a balloon. The abdominal section of the aorta supplies blood to the lower body.

Aneurysm—A weakening of the artery wall due to atherosclerosis, causing a bulge that can rupture, and lead to thrombosis or embolism.

Angiography or angiogram—An x-ray exam of the arteries and veins (blood vessels) to diagnose blockages and other blood vessel problems.

Atherosclerosis—A form of arteriosclerosis affecting the innermost area of the artery; a series of calcified deposits that can close down the vessel.

Arteriogram—An x-ray picture of an artery achieved by injecting an opaque dye with a needle or tube into the affected artery.

Artery—A blood vessel conveying blood in a direction away from the heart.

Bruit—A roaring sound created by a partially blocked artery.

Capillary—Smallest extremity of the arterial vessel, where oxygen and nutrients are released from the blood into the cells, and cellular waste is collected.

Carotid artery—Major artery leading to the brain, blockages of which can cause temporary or permanent strokes.

Carotid artery disease—A condition in which the arteries in the neck that supply blood to the brain become clogged, causing the danger of a stroke.

Carotid endarterectomy—A surgical technique for removing intra-arterial obstructions of the internal carotid artery.

Cerebral aneurysm—The dilation, bulging, or ballooning out of part of the wall of a vein or artery in the brain.

Cholesterol—An abundant fatty substance in animal tissues. High levels in the diet are a factor in the cause of atherosclerosis.

Claudication—Attacks of lameness or pain chiefly in the calf muscles, brought on by walking because of a lack of oxygen reaching the muscle.

Computed tomography (CT) scan—A special type of x ray that can produce detailed pictures of structures inside the body.

Collaterals—Alternate pathways for arterial blood.

- obesity
- hypertension, diabetes, high cholesterol, or other conditions that affect the health of the cardiovascular system
- lack of exercise

Description

Vascular surgery involves techniques relating to endovascular surgeries, including balloon **angioplasty** and/or stenting, aortic and peripheral vascular endovascular stent/graft placement, thrombolysis, and other adjuncts for vascular reconstruction.

The vascular system is the network of blood vessels that circulate blood to and from the heart and lungs. The circulatory system (made up of the heart, arteries, veins, capillaries, and the circulating blood) provides nourishment to the body's cells and removes their waste. The arteries carry oxygenated blood from the heart to the cells. The veins return the blood from the cells back to the lungs for reoxygenation and recirculation by the heart. The aorta is the largest artery leaving the heart; it then subdivides into smaller arteries going to every part of the body. The arteries, as they narrow, are connected to smaller vessels called capillaries. In these capillaries, oxygen and nutrients are released from the blood into the cells, and cellular wastes are

Coronary—Of or relating to the heart.

Embolism—Obstruction or closure of a vessel by a transported clot of foreign matter.

Endovascular grafting—A procedure that involves the insertion of a delivery catheter through a groin artery into the abdominal aorta under fluoroscopic guidance.

Intracranial—Existing or occurring within the cranium; affecting or involving intracranial structures.

Lower extremity amputation—To cut a limb from the body.

Lymphangiography—Injection of dye into lymphatic vessels followed by x rays of the area. It is a difficult procedure, as it requires surgical isolation of the lymph vessels to be injected.

Lymphoscintigraphy—A technique in which a radioactive substance that concentrates in the lymphatic vessels is injected into the affected tissue and mapped using a gamma camera, which images the location of the radioactive tracer.

Magnetic resonance imaging (MRI)—A noninvasive diagnostic technique that produces computerized images of internal body tissues and is based on nuclear magnetic resonance of atoms within the body induced by the application of radio waves.

Plethysmography—A test in which a patient sits inside a booth called a plethysmograph and breathes through a mouthpiece, while pressure and air flow measurements are collected to measure the total lung volume.

Pulmonary embolism—A blocked artery in the lung.

Renal artery aneurysm—An aneurysm relating to, involving, or located in the region of the kidneys.

Thoracic aortic aneurysm—Occurs when an area in the thoracic section of the aorta (the chest) is weakened and bulges like a balloon. The thoracic section supplies blood to the upper body.

Thrombolysis—A treatment that opens up blood flow and may prevent permanent damage to the blood vessels.

Thrombosis—The formation or presence of a blood clot within a blood vessel.

Thrombus—A blood clot that may form in a blood vessel or in one of the cavities of the heart.

Ulcer—A lesion or rough spot formed on the surface of an artery.

Ultrasound scan—The scan produces images of arteries on a screen and is used to evaluate the blood flow, locate blockages, and measure the size of the artery.

Varicose veins —Twisted, enlarged veins near the surface of the skin, which develop most commonly in the legs and ankles.

Vascular—Relating to the blood vessels.

Vasculogenic erectile dysfunction—The inability to attain or sustain an erection satisfactory for coitus, due to atherosclerotic disease of penile arteries, inadequate impedance of venous outflow (venous leaks), or a combination of both.

Venous stasis disease—A condition in which there is pooling of blood in the lower leg veins that may cause swelling and tissue damage, and lead to painful sores or ulcers.

collected for the return trip. The capillaries then connect to veins, which return the blood back to the heart.

The aorta stems from the heart, arches upward, and then continues down through the chest (thorax) and the abdomen. The iliac arteries, which branch out from the aorta, provide blood to the pelvis and legs. The thoracic section of the aorta supplies blood to the upper body, as it continues through the chest. The abdominal section of the aorta, which supplies blood to the lower body, continues through the abdomen.

Vascular diseases are usually caused by conditions that clog or weaken blood vessels, or damage valves that control the flow of blood in and out of the veins, thus robbing them of vital blood nutrients and oxygen. A few common diseases affecting the arteries are peripheral vascular disease (PVD), carotid artery disease, and aortic aneurysms.

Surgery is used to treat specific diseased arteries, such as **atherosclerosis**, to help prevent strokes or heart attacks, improve or relieve **angina** or **hypertension**, remove aneurysms, improve claudication, and save legs that would otherwise have to be amputated. The choices involve repairing the artery, bypassing it, or replacing it.

As people age, atherosclerosis, commonly called hardening of the arteries, occurs with the constant passage of blood through the arteries. It can take on a

number of forms, of which atherosclerosis (hardening of the innermost portion) is the most common. This occurs when fatty material containing cholesterol or **calcium** (plaque) is deposited on the innermost layer of the artery. This causes a narrowing of the inside diameter of the blood vessel. Eventually, the artery becomes so narrow that a blood clot (thrombus) forms, and blocks blood flow to an entire portion of the body. This condition is called PVD, or peripheral arterial disease. In another form of atherosclerosis, a rough area or ulcer forms in the diseased interior of the artery. Blood clots then tend to develop on this ulcer, break off, and travel further along, forming a blockage where the arteries get narrower. A blockage resulting from a clot formed elsewhere in the body is called an **embolism**.

People who have few areas affected by PVD may be treated with angioplasty by opening up the blood vessel with a balloon placed on the end of a catheter. A stent is often used with angioplasty to help keep the artery open. The type of surgery used to treat PVD is based upon the size and location of the damaged artery. The surgery techniques used for severe PVD include:

- Bypass surgery is preferred for people who have many areas of blockage or a long, continuous blockage.
- Aortobifemoral bypass is used for PVD affecting the major abdominal artery (aorta) and the large arteries that branch off of it.
- In a technique called thromboendarterectomy, the inner diseased layers of the artery are removed, leaving the relatively normal outer coats of the artery.
- Resection involves a technique to remove a diseased artery following an aneurysm; a bypass is created with a synthetic graft.
- In a bypass graft, a vein graft from another part of the body or a graft made from artificial material is used to create a detour around a blocked artery.
- Tibioperoneal bypass is used for PVD affecting the arteries in the lower leg or foot.
- Femoropopliteal (fem-pop) bypass surgery is used for PVD affecting the arteries above and below the knee.
- Embolectomy is a technique in which an embolic clot on the wall of the artery is removed, using an inflatable balloon catheter.
- Thrombectomy is a technique in which a balloon catheter is inserted into the affected artery beyond a blood clot. The balloon is then inflated and pulled back, bringing the clot with it.

An aneurysm occurs when weakened blood vessels bulge like balloons as blood flows through them. Once they have grown to a certain size, there is a risk of rupture and life-threatening bleeding. There are two types of aortic aneurysms: abdominal **aortic aneurysm** (AAA) and thoracic aortic aneurysm. This classification is based on where the aneurysm occurs along the aorta. Aneurysms are more common in the abdominal section of the aorta than the thoracic section.

Most blood clots originate in the legs, but they can also form in the veins of arms, the right side of the heart, or even at the tip of a catheter placed in a vein. Venous disease conditions that usually occur in the veins of the legs include:

- varicose veins
- phlebitis
- venous stasis disease
- deep vein thrombosis (DVT)
- claudication
- blood clots

Carotid artery disease is a condition in which the arteries in the neck that supply blood to the brain become clogged; this condition can cause a **stroke**.

Lymphatic obstruction involves blockage of the lymph vessels, which drain fluid from tissues throughout the body and allow immune cells to travel where they are needed. Some of the causes of lymphatic obstruction (also known as swelling of the lymph passages), include infections such as chronic **cellulitis**, or parasitic infections such as **filariasis**, trauma, tumors, certain surgeries including **mastectomy**, and **radiation therapy**. There are rare forms of congenital **lymphedema** that probably result from abnormalities in the development of the lymphatic vessels. Most patients with lymphedema will not need surgery, as the symptoms are usually managed by other techniques. Surgical therapy for lymphedema includes removal of tissue containing abnormal lymphatics and, less commonly, transplant of tissue from areas with normal lymphatic tissues to areas with abnormal lymphatic drainage. In rare cases, bypass of abnormal lymphatic tissue is attempted, sometimes using vein grafts.

Other examples of vascular surgery include:

- cerebral aneurysm
- acute arterial and graft occlusion
- carotid endarterectomy
- endovascular grafting
- vasculogenic erectile dysfunction
- renal artery aneurysm
- surgery on varicose veins
- lower extremity amputation

Diagnosis/Preparation

In order for a patient to be diagnosed with a vascular disease, he or she must be clinically evaluated

by a vascular surgeon, which includes a history and **physical examination**. A vascular surgeon also treats vascular disorders by non-operative means, including drug therapy and risk factor management.

The symptoms produced by atherosclerosis, thrombosis, embolisms, or aneurysms depend on the particular artery affected. These conditions can sometimes cause **pain**, but often there are no symptoms at all.

A physician has many ways of feeling, hearing, measuring, and even seeing arterial blockages. Many arteries in the body can be felt or palpated. A doctor can feel for a pulse in an area he or she believes afflicted. Usually, the more advanced the arteriosclerosis, the less pulse in a given area.

As the artery becomes blocked, it can cause a noise very much like water roaring over rocky rapids. The physician can listen to this noise (bruit) directly, or can use special amplification systems to hear the noise.

There are other tests that can be done to determine if arterial blood flow is normal, including:

- ankle-brachial index (ABI) test
- arteriogram
- segmental pressure test
- ultrasound scan
- magnetic resonance imaging (MRI)
- computed tomography (CT) scan
- angiography
- lymphangiography
- lymphoscintigraphy
- plethysmography
- duplex ultrasound scanning

There may be no symptoms of vascular disease caused by blood clots until the clot grows large enough to block the flow of blood through the vein. Symptoms that may come on suddenly include:

- pain
- sudden swelling in the affected limb
- reddish blue discoloration
- enlargement of the superficial veins
- skin that is warm to the touch

The physician will probably do an evaluation of all organ systems, including the heart, lungs, circulatory system, kidneys, and the gastrointestinal system. The decision whether to have surgery or not is based on the outcome of these evaluations.

For high-risk patients undergoing vascular surgery, research has shown that taking oral beta-blockers one to two weeks before surgery and continuing for at least two weeks after the operation can significantly reduce the chance of dying or having a **heart attack**. Scientists suspect that the drug improves oxygen balance in the wall of the heart and stabilizes plaques in the arteries.

Aftercare

The length of time in intensive care and hospitalization will vary with each surgery, as will the recovery time, depending on numerous factors. Because surgery for an abdominal aortic aneurysm (AAA) is more serious, the patient can expect to be in intensive care for 24 hours, and in the hospital for 5–10 days, providing the patient was healthy and had a smooth operative and postoperative course. The hospital stay will likely increase if there are complications. It may take as long as six months to fully recover from surgery for an AAA.

Living a heart-healthy lifestyle is the best way of preventing and controlling vascular disease: quit **smoking**; eat nutritious foods low in fat; **exercise**; maintain a healthy weight; and control risk factors such as high blood pressure, high cholesterol, diabetes, hypertension, and other factors that contribute to vascular disease.

Medications that may be used to treat PVD include:

- aspirin and other antiplatelet medications to treat leg pain
- statins to lower cholesterol levels
- medications to control high blood pressure
- medications to control diabetes
- anticoagulants (these are rarely, but not generally, used to treat PVD unless the person is at an increased risk for forming blood clots)

Risks

All surgeries carry some risks. There is a risk of infection whenever incisions are required. Operations in the chest or those that involve major blood vessels carry a higher risk of complications. Patients that have high blood pressure, chronic lung or **kidney disease**, or other illnesses are at greater risk of complications during and after surgery. Other risks of vascular surgery include:

- bleeding
- failed or blocked grafts

- heart attack or stroke
- smoking
- leg swelling if a leg vein is used
- people over 65 years are at greater risk for brain impairment after major surgery
- the more damaged the circulatory system is before surgery, the higher susceptibility to mental decline after vascular surgery
- impotence

The patient should discuss risks with the surgeon after careful review of the patient's medical history and a physical examination.

Normal results

The success rate for vascular surgery varies depending on a number of factors that may influence the decision on whether to have surgery or not, as well as the results.

The chance that an aneurysm will rupture generally increases with the size of the aneurysm; AAAs smaller than 1.6 in (4 cm) in diameter have up to a 2% risk of rupture, while ones larger than 2 in (5 cm) in diameter have a 22% risk of rupture within two years.

Arterial bypass surgery and peripheral bypass surgery have very good success rates. Most of those who undergo AAA surgery recover well, except in the case of a rupture. Most patients who have a ruptured aortic aneurysm die due to excessive, rapid blood loss.

Surgical therapy for lymphedema has met with limited success and requires significant experience and technical expertise.

Morbidity and mortality rates

Peripheral vascular disease affects 10 million people in the United States, including 5% of those over 50. Only a quarter of PVD sufferers are receiving treatment. More than two million people in the United States develop DVT each year. More than 650,000 Americans experience a **pulmonary embolism** every year. Of those, approximately 200,000 people die from the condition.

Alternatives

There a few alternatives to treating vascular disease, although extensive research has not been done. **Acupuncture** is used to aid in hypertension and **chelation therapy** is thought to stabilize the effects of vascular disease. The focus should be on maintaining a proper diet and being aware of a family history of vascular disease so as to catch it as early as possible.

Vasculitis

Definition

Vasculitis refers to a varied group of disorders which all share a common underlying problem of inflammation of a blood vessel or blood vessels. The inflammation may affect any size blood vessel, anywhere in the body. It may affect either arteries and/or veins. The inflammation may be focal, meaning that it affects a single location within a vessel, or it may be widespread, with areas of inflammation scattered throughout a particular organ or tissue, or even affecting more than one organ system in the body.

Description

Inflammation is a process which occurs when the immune system of the body responds to either an injury or a foreign invader (virus, bacteria, or fungi). The immune system response involves sending a variety of cells and chemicals to the area in question. Inflammation causes blood vessels in the area to leak, causing swelling. The inflamed area becomes red, hot to the touch, and tender.

Antibodies are immune cells which recognize and bind to specific markers (called antigens) on other cells (including bacteria and viruses). These antibody-antigen complexes can then stimulate the immune system to send a variety of other cells and chemicals involved in inflammation to their specific location.

Some researchers believe that the damaging process of vasculitis is kicked off by such antibody-antigen complexes. These complexes are deposited along the walls of the blood vessels. The resulting inflow of immune cells and chemicals causes inflammation within the blood vessels.

The type of disease caused by vasculitis varies depending on a number of factors:

- the organ system or tissue in which the vasculitis occurs
- the specific type of inflammatory response provoked
- whether the affected vessels are veins (which bring blood to the heart) or arteries (which carry blood and oxygen from the heart to the organs and tissues)
- the degree to which blood flow within the affected vessel is reduced

This person's legs are afflicted with leukocytoblastic vasculitis, a condition in which a blood or lymph vessel becomes inflamed. *(Custom Medical Stock Photo, Inc. Reproduced by permission.)*

Causes and symptoms

Some types of vasculitis appear to be due to a type of allergic response to a specific substance (for example, a drug). Other types of vasculitis have no identifiable initiating event. Furthermore, researchers have not been able to consistently identify antibody-antigen complexes in all of the types of diseases caused by vasculitis. The types of antigens responsible for the initial immune response have often gone unidentified as well. Furthermore, not all people with such complexes deposited along the blood vessels go on to develop vasculitis. Some researchers believe that, in addition to the presence of immune complexes, an individual must have some other characteristics which make him or her susceptible to vasculitis. Many questions have yet to be answered to totally explain the development these diseases.

Symptoms

Symptoms of vasculitis depend on the severity of the inflammation and the organ system or systems affected. Some types of vasculitis are so mild that the only symptoms noted are small reddish-purple dots (called petechiae) on the skin due to tiny amounts of blood seeping out of leaky blood vessels. In more widespread types of vasculitis, the patient may have general symptoms of illness, including **fever**, achy muscles and joints, decreased appetite, weight loss, and loss of energy. The organ systems affected by vasculitis may include:

- The skin. Rashes, bumps under the skin, petechiae, larger reddish-purple circles (purpura), or bruising (ecchymoses) may appear. Areas of skin totally deprived of blood flow, and therefore of oxygen, may die, resulting in blackened areas of gangrene.
- The joints. In addition to joint pain, the joints themselves may become inflamed, resulting in arthritis.
- Brain and nervous system. Inflammation of the blood vessels in the brain can cause headaches, changes in personality, confusion, and seizures. If an area of the brain becomes totally deprived of oxygen, a stroke occurs. A stroke means that an area of brain tissue is either severely injured or completely dead from lack of oxygen. This may leave the individual with a permanent disability. If the vessels that lead to the eyes are affected, vision may become seriously disturbed. Nerves in the arms and legs may result in painful tingling sensations, loss of feeling, and weakness.
- Gastrointestinal system. Patients may have significant abdominal pain, vomiting, and diarrhea. If blood flow is completely cut off to an area of intestine, that part of the intestine will die off. The liver may be affected.
- Heart. This is an extremely serious type of vasculitis. The arteries of the heart (coronary arteries) may develop weakened areas, called aneurysms. The heart muscle itself may become inflamed and enlarged. With oxygen deprivation of the heart muscle, the individual may suffer a heart attack.
- Lungs. The patient may experience shortness of breath with chest pain, and may cough up blood. There may be wheezing.
- Kidney. Changes in the arteries of the kidney may result in high blood pressure. The kidneys may become increasingly unable to appropriately filter the blood, and kidney failure may occur.

Specific diseases

Multiple types of disease are associated with vasculitis. Many autoimmune diseases have vasculitis as one of their complications. These include **systemic lupus erythematosus**, **rheumatoid arthritis**, **scleroderma**, and **polymyositis**. Other types of diseases which have vasculitis as their major manifestations include:

- Polyarteritis nodosa. This is an extremely serious, systemic (affecting systems throughout the body) form of vasculitis. Small and medium arteries are involved, and the inflammation is so severe that the walls of the arteries may be destroyed. Any organ system, or multiple organ systems, may be affected. The most serious effects include kidney failure, complications involving the heart, gastrointestinal problems, and high blood pressure.
- Kawasaki's disease is an acute disease which primarily strikes young children. Fever and skin manifestations occur in all patients. While most patients recover completely, a few patients suffer from vasculitis in the heart. This is frequently fatal.
- Henoch-Schonlein purpura. While this frequently occurs in children, adults may also be affected. This disease tends to affect the skin, joints, gastrointestinal tract, and kidneys.
- Serum sickness occurs when an individual reacts to a component of a drug, for example penicillin. Symptoms of this are often confined to the skin, although fevers, joint pain, and swelling of lymph nodes may also occur.
- Temporal arteritis (also called giant cell arteritis) tends to involve arteries which branch off the major artery that leads to the head, called the carotid. An artery which feeds tissues in the area of the temple (the temporal artery) is often affected. Severe headaches are the most classic symptom. Other symptoms include fatigue, loss of appetite and then weight, fever, heavy sweating, joint pain, and pain in the muscles of the neck, shoulders, and back. If the vasculitis includes arteries which supply the eye, serious visual disturbance or even blindness may result.
- Takayasu's arteritis affects the aorta (the very large main artery that exits the heart and receives all of the blood to be delivered throughout the body), and arteries which branch off of the aorta. Initial symptoms include fatigue, fever, sweating at night, joint pain, and loss of appetite and weight. Every organ may be affected by this disease. A common sign of

KEY TERMS

Aneurysm—A weakened area in the wall of a blood vessel which causes an outpouching or bulge. Aneurysms may be fatal if these weak areas burst, resulting in uncontrollable bleeding.

Antibody—Specialized cells of the immune system which can recognize organisms that invade the body (such as bacteria, viruses, and fungi). The antibodies are then able to set off a complex chain of events designed to kill these foreign invaders.

Antigen—A special, identifying marker on the outside of cells.

Autoimmune disorder—A disorder in which the body's antibodies mistake the body's own tissues for foreign invaders. The immune system therefore attacks and causes damage to these tissues.

Immune system—The system of specialized organs, lymph nodes, and blood cells throughout the body which work together to prevent foreign invaders (bacteria, viruses, fungi, etc.) from taking hold and growing.

Inflammation—The body's response to tissue damage. Includes hotness, swelling, redness, and pain in the affected part.

Petechia—A tiny, purplish-red spot on the skin. Caused by the leakage of a bit of blood out of a vessel and under the skin.

Purpura—A large, purplish-red circle on the skin. Caused by the leakage of blood out of a vessel and under the skin.

this disease is the inability to feel the pulse in any of the usual locations (the pulse is the regular, rhythmic sensation one can feel with a finger over an artery, for example in the wrist, which represents the beating of the heart and the regular flow of blood).

- Wegener's granulomatosis: This disease exerts its most serious effects on the respiratory tract. The vasculitis produced by this disease includes the formation of fibrous, scarring nodules called granulomas. Symptoms include nose bleeds, ear infections, cough, shortness of breath, and chest pain. There may be bleeding in the lungs, and a patient may cough up blood. The kidneys, eyes, and skin are also frequently involved.

Diagnosis

Diagnosis of any type of vasculitis involves demonstrating the presence of a strong inflammatory process. Tests which reveal inflammation throughout the body include **erythrocyte sedimentation rate**, blood tests which may reveal anemia and increased white blood cells, and tests to demonstrate the presence of immune complexes and/or antibodies circulating in the blood. An x-ray procedure, called **angiography**, involves injecting dye into a major artery, and then taking x-ray pictures to examine the blood vessels, in order to demonstrate the presence of inflammation of the vessel walls. Tissue samples (biopsies) may be taken from affected organs to demonstrate inflammation.

Treatment

Even though there are many different types of vasculitis, with many different symptoms based on the organ system affected, treatments are essentially the same. They all involve trying to decrease the activity of the immune system. Steroid medications (like prednisone) are usually the first types of drugs used. **Steroids** work by interfering with the chemicals involved in the inflammatory process. More potent drugs for severe cases of vasculitis have more serious side effects. These include drugs like cyclophosphamide. Cyclophosphamide works by actually killing cells of the patient's immune system.

Prognosis

The prognosis for vasculitis is quite variable. Some mild forms of vasculitis, such as those brought on by reactions to medications, may resolve totally on their own and not even require treatment. **Temporal arteritis**, **serum sickness**, Henoch-Schonlein purpura, and Kawasaki's disease usually have excellent prognoses, although when Kawasaki's affects the heart, there is a high **death** rate. Other types of vasculitis were always fatal, prior to the availability of prednisone and cyclophosphamide, and continue to have high rates of fatal complications. These include polyarteritis nodosa and **Wegener's granulomatosis**.

Prevention

Because so little is known about what causes a particular individual to develop vasculitis, there are no known ways to prevent it.

Vasectomy

Definition

A vasectomy is a surgical procedure performed on males in which the vas deferens (tubes that carry sperm from the testicles to the seminal vesicles) are cut, tied, cauterized (burned or seared) or otherwise interrupted. The semen no longer contains sperm after the tubes are cut, so conception cannot occur. The testicles continue to produce sperm, but they die and are absorbed by the body.

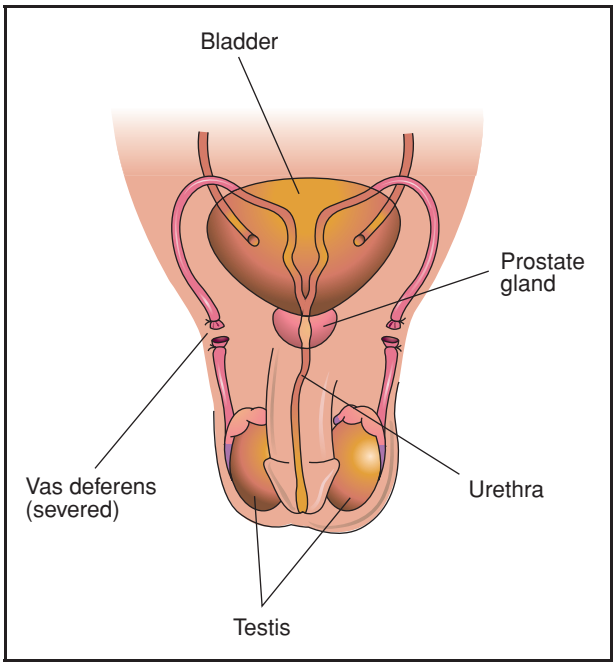
Purpose

The purpose of this operation is to provide reliable **contraception**. Research indicates that the level of effectiveness is 99.6%. Vasectomy is the most reliable method of contraception.

Description

Vasectomies are often performed in the doctor's office using a **local anesthesia**. The patient's scrotum area will be shaved and cleaned with an antiseptic solution to reduce the chance of infection. A small incision is made into the scrotum (the sac containing the testicles that produce the sperm). Each of the vas deferens (one from each testicle) is tied in two places with nonabsorbable (permanent) sutures and the tube is severed between the ties. The ends may be cauterized (burned or seared) to decrease the chance that they will leak or grow back together.

Sterility does not occur immediately after the procedure is finished. Men must use other methods of contraception until two consecutive semen analyses confirm that there are no sperm present in the semen.



Vasectomy is a surgical procedure performed on males in which the vas deferens (tubes that conduct sperm from the testicles to the penis) are cut, tied, cauterized, or otherwise interrupted. Although the testicles still produce sperm, the sperm die and are absorbed by the body. Men who have had vasectomies may continue to ejaculate the same amount of semen as before the procedure. *(Illustration by Electronic Illustrators Group. Reproduced by permission of Gale, a part of Cengage Learning.)*

This will take four to six weeks or 15–20 ejaculations to clear all of the sperm from the tubes.

"No scalpel" vasectomies are gaining popularity. Instead of an incision, a small puncture is made into the scrotum. The vas deferens are cut and sealed in a manner similar to that described above. No stitches are necessary and the patient has less **pain**. Other advantages include less damage to the tissues, less bleeding, less risk of infection, and less discomfort after the procedure.

In some, cases vasectomies may be reversed. However, this procedure should be considered permanent as there is no guarantee of successful reversal.

Preparation

No special physical preparation is required. The physician will first assess the patient's general health in order to identify any potential problems that could occur. The doctor will then explain possible risks and side effects. The patient is asked to sign a consent form which indicates that he understands the information he has received, and gives the doctor permission to perform the operation.

KEY TERMS

Ejaculation—The act of expelling the sperm through the penis during orgasm.

Epididymitis—Inflammation of the small tube that rests on top of the testicle and is part of the system that carries sperm from the testicle to the penis. The condition can be successfully treated with antibiotics if necessary.

Scrotum—The sac which contains the testicles.

Sperm granuloma—A collection of fluid that leaks from an improperly sealed or tied vas deferens. They usually disappear on their own, but can be drained if necessary.

Testicles—The two egg-shaped organs found in the scrotum that produce sperm.

Tubal ligation—A surgical procedure in which the fallopian tubes are tied in two places and cut between. This prevents eggs from moving from the ovary to the uterus.

Aftercare

Following the surgery, ice packs are often applied to scrotum to decrease pain and swelling. A dressing (or athletic supporter) which supports the scrotum can also reduce pain. Mild over-the-counter pain medication such as **aspirin** or **acetaminophen** (Tylenol) should be able to control any discomfort. Activities may be restricted for one or two days and sexual intercourse for three to four days.

Risks

There are very few risks associated with vasectomy other than infection, bruising, **epididymitis** (inflammation of the tube that carries the sperm from the testicle to the penis), and sperm granulomas (collection of fluid that leaks from a poorly sealed or tied vas deferens). These are easily treated if they do occur. Patients do not experience difficulty achieving an erection, maintaining an erection, or ejaculating. There is no decrease in the production of the male hormone (testosterone), and sex drive and ability are not altered. Vasectomy is safer and less expensive than **tubal ligation** (sterilization of a female by cutting the fallopian tube to prevent conception).

Normal results

Normally, vasectomies are 99% successful in preventing conception. As such, it is one of the most effective methods available to consumers.

Vasodilators

Definition

Vasodilators are medicines that act directly on muscles in blood vessel walls to make blood vessels widen (dilate).

Purpose

Vasodilators are used to treat high blood pressure (**hypertension**). By widening the arteries, these drugs allow blood to flow through more easily, reducing blood pressure. Controlling high blood pressure is important because the condition puts a burden on the heart and the arteries, which can lead to permanent damage over time. If untreated, high blood pressure increases the risk of **heart attack**, **heart failure**, **stroke**, or kidney failure. Vasodilators usually are prescribed with other types of blood pressure drugs and rarely are used alone.

Description

Examples of vasodilators are hydralazine (Apresoline) and **minoxidil** (Loniten). The vasodilator hydralazine also may be used to control high blood pressure in pregnant women or to bring down extremely high blood pressure in emergency situations. In the forms used for treating high blood pressure (tablets or injections), these drugs are available only with a physician's prescription. A liquid form of minoxidil, used to promote hair growth in people with certain kinds of baldness and is applied directly to the scalp, and is sold without a prescription.

Recommended dosage

The recommended dosage depends on the type of vasodilator. The physician who prescribed the drug or the pharmacist who filled the prescription can

recommend the correct dosage. This medicine should only be used as directed.

Physicians usually prescribe vasodilators along with other blood pressure medicines. Taking each drug at the correct time is extremely important. Health care providers can offer suggestions on how to remember when to take each drug.

Precautions

Seeing a physician regularly while taking a vasodilator is important, especially during the first few months. The physician will check to make sure the medicine is working as it should and will watch for unwanted side effects. People who have high blood pressure often feel fine. However, even when they feel well, patients should keep seeing their physicians and taking their medicine.

Vasodilators will not cure high blood pressure, but will help control the condition. To avoid the serious health problems that high blood pressure can cause, patients may have to take medicine for the rest of their lives. Furthermore, medicine alone may not be enough. People with high blood pressure also may need to avoid certain foods and keep their weight under control. The health care professional who is treating the condition can offer advice on what measures may be necessary.

Some people feel dizzy or have headaches while using this medicine. These problems are especially likely to occur in older people, who are more sensitive than younger people to the medicine's effects. Anyone who takes these drugs should not drive, use machines, or do anything else that might be dangerous until they know how the drugs affect them.

Special conditions

People who have certain medical conditions or who are taking certain other medicines may have problems if they take vasodilators. In the past, patients with severe aortic stenosis could not use vasodilators because they could cause blood pressure to drop too low and result in severe complications. However, in 2003, a report announced that the vasodilator nitroprusside was safe in these patients and rapidly improved their cardiac function. Before a patient takes vasodilators, he or she should be sure to let the physician know about any of these conditions:

ALLERGIES. Anyone who has had an unusual reaction to a vasodilator in the past should let his or her physician know before taking this type of drug again. The physician also should be told about any **allergies** to foods, dyes, preservatives, or other substances.

PREGNANCY. Several problems—from excess hair growth to blood abnormalities—have been reported in babies whose mothers take certain vasodilators during **pregnancy**. In studies of laboratory animals, hydralazine caused **birth defects** in mice and rabbits, but not in rats. The effects of taking vasodilators during pregnancy have not been specifically studied in humans. Women who are pregnant or who may become pregnant should check with their physicians before using this medicine. Women who become pregnant while taking a vasodilator should tell their physicians right away.

BREASTFEEDING. Women who are **breastfeeding** their babies or who plan to breastfeed should check with their physicians before using this medicine.

OTHER MEDICAL CONDITIONS. Using a vasodilator to lower blood pressure may worsen the problems that result from heart disease, blood vessel disease, or a recent heart attack or stroke. This medicine also may make **angina** (chest **pain**) worse. Vasodilators may make pheochromocytomas (tumors of the adrenal medulla), more active. Before using a vasodilator, people with any of these medical problems should make sure their physicians are aware of their conditions.

People with **kidney disease** also should check with their physicians before using a vasodilator. Side effects may be greater in these people because their kidneys are slow to clear the medicine from the body.

USE OF CERTAIN MEDICINES. Taking vasodilators with certain other drugs may affect the way the drugs work or may increase the chance of side effects. Any other prescription or nonprescription (over-the-counter) medicine should not be taken along with a vasodilator unless it has been discussed with the physician who prescribed the vasodilator.

Side effects

Some side effects of vasodilators go away as the body adjusts to the drug and do not need medical attention unless they continue or interfere with normal activities. These include:

- headache
- nausea or vomiting
- diarrhea
- loss of appetite

In addition, minoxidil may cause a temporary increase in hair growth, especially on the face, arms, and back. Patients who are bothered by this should check with their physicians.

KEY TERMS

Adrenal gland—One of a pair of organs located next to the kidneys. The adrenal glands produce hormones that control many body functions.

Adrenal medulla—The inner part of the adrenal gland. The adrenal medulla produces the hormones epinephrine (adrenaline), which stimulates the heart, tightens blood vessels, and relaxes some smooth muscles, and norepinephrine, which has similar effects.

Arteries—Blood vessels that carry blood away from the heart to the cells, tissues, and organs of the body.

Other side effects of vasodilators should have medical attention. Rapid or irregular heartbeat are reasons to check with a physician immediately. If any of the following problems occur, a physician should be consulted as soon as possible:

- chest pain
- muscle pain
- joint pain
- pain, numbness, tingling, or weakness in the hands or feet
- swollen feet or lower legs
- swollen lymph nodes
- bloating
- fever and sore throat
- general discomfort or feeling of illness
- weakness
- blisters on skin; skin rash or itching; flushing or redness of the skin

Additional side effects are possible. Anyone who has unusual symptoms while taking a vasodilator should get in touch with his or her physician.

Interactions

Vasodilators may interact with other medicines. When this happens, the effects of one or both of the drugs may change or the chance of side effects may be greater. In addition, many prescription and nonprescription (over-the-counter) drugs may affect blood pressure. *No other medication should be taken without the approval of the physician who prescribed the vasodilator*. In particular, avoiding over-the-counter medicines for appetite control, colds, **cough**, sinus problems, **asthma**, hay fever, and other allergies, should be avoided as these may increase blood pressure. At the other extreme, dangerously low blood pressure may result when drugs such as the blood pressure medicine guanethidine (Ismelin) or nitrates, used to treat chest pain, are combined with vasodilators.

Vegetarianism

Definition

Vegetarianism is the voluntary abstinence from eating meat. Vegetarians refrain from eating meat for various reasons, including religious, health, and ethical ones. Lacto-ovo vegetarians supplement their diet with dairy (lactose) products and eggs (ovo). Vegans (pronounced vee-guns) do not eat any animal-derived products at all.

Purpose

Vegetarianism is recommended as a dietary therapy for a variety of conditions, including heart disease, high cholesterol, type 2 diabetes, and **stroke**. Vegetarianism is a major dietary therapy in the alternative treatment of **cancer**. Other conditions treated with a dietary therapy of vegetarianism include **obesity**, **osteoporosis**, arthritis, **allergies**, **asthma**, environmental illness, **hypertension**, **gout**, **gallstones**, **hemorrhoids**, **kidney stones**, ulcers, **colitis**, **premenstrual syndrome**, **anxiety**, and depression. Vegetarians often report higher energy levels, better digestion, and mental clarity. Vegetarianism is an economical and easily implemented preventive practice as well.

DR. JOHN HARVEY KELLOGG (1852–1943)

(AP Images.)

John Harvey Kellogg is known as the father of modern breakfast cereal. He was born in Tyrone Township, Michigan, on February 26, 1852, into a Seventh Day Adventist family. At age 12, he became an apprentice at the Review and Herald Press, a publishing company run by the church. He attended school in Battle Creek, Michigan.

He attended Bellevue Hospital Medical College in New York where he received his medical degree in 1875. In 1876, at the age of 24, Kellogg became an abdominal surgeon and superintendent of the Western Health Reform Institute, which he renamed the Battle Creek Sanitarium. There, he began applying his theories about natural living to his medical practice. As a vegetarian, he first advocated a diet high in whole grains, fruits, nuts, and legumes. He later included all types of vegetables in the diet. His controversial health regimen included morning calisthenics, open-air sleeping, cleansing enemas, chewing food hundreds of times before swallowing, and drinking plenty of water.

In the 1890s, Kellogg established a laboratory at the sanitarium to develop more nutritious foods. His brother, Will Keith Kellogg, joined in his research. In 1895 they developed a breakfast cereal of wheat flakes called Granose. The cereal quickly grew in popularity and was soon sold by mail order. This was followed by rice flakes and corn flakes. The brothers established the Sanitas Food Company. However, philosophical differences led them to split into two companies. Will founded the W. K. Kellogg Company, which retained the rights to the cereal products. John set up the Battle Creek Food Company, which produced coffee substitutes and soymilk. John Kellogg also edited *Good Health Magazine*, which promoted vegetarianism, for 60 years. In 1904, he published a book, *The Miracle of Life*. He continued to promote his version of healthy living and radical techniques until his death in 1943.

Description

The term vegetarian was coined in 1847 by the founders of the Vegetarian Society of Great Britain, but vegetarianism has been around as long as people have created **diets**. Some of the world's oldest cultures advocate a vegetarian diet for health and religious purposes. In India, millions of Hindus are vegetarians because of their religious beliefs. One of the ancient mythological works of Hinduism, the *Mahabharata*, states that, "Those who desire to possess good memory, beauty, long life with perfect health, and physical, moral and spiritual strength, should abstain from animal foods." The **yoga** system of living and health is vegetarian, because its dietary practices are based on the belief that healthy food contains *prana*. Prana is the universal life energy, which yoga experts believe is abundant in fresh fruits, grains, nuts and vegetables, but absent in meat because meat has been killed. Yogis also believe that spiritual health is influenced by the practice of *ahimsa*, or not harming living beings. The principle of *ahimsa* (non-violence) appears in the Upanishads (Vedic literature) from c. 600–300 B.C. Taking of animal life or human life under any circumstances is sinful and results in rebirth as a lower organism. It became a fundamental element of Jainism, another religion of India. Some Buddhists in Japan and China are also vegetarian because of spiritual beliefs. In the Christian tradition, the Trappist Monks of the Catholic Church are vegetarian, and some vegetarians argue that there is evidence that Jesus and his early followers were vegetarian. Other traditional cultures, such as those in the Middle East and the Mediterranean regions, have evolved diets that frequently consist of vegetarian foods. The **Mediterranean diet**, which a Harvard study declared to be one of the world's healthiest, is primarily, although not strictly, vegetarian.

The list of famous vegetarians forms an illustrious group. The ancient Greek philosophers, including Socrates, Plato, and Pythagoras, advocated vegetarianism.

In modern times, the word to describe someone who likes to feast on food and wine is "epicure," but it is little known that Epicurus, the ancient philosopher, was himself a diligent vegetarian. Other famous vegetarians include Leonardo da Vinci, Sir Isaac Newton, Leo Tolstoy, Ralph Waldo Emerson, and Henry Thoreau. The twentieth century's celebrated vegetarians include Gandhi, the physician Albert Schweitzer, writer George Bernard Shaw, musician Paul McCartney, and champion triathlete Dave Scott. Albert Einstein, although not a strict vegetarian himself, stated that a vegetarian diet would be an evolutionary step for the human race.

Vegetarianism in the United States received a lot of interest during the last half of the nineteenth century and the beginning of the twentieth century, during periods of experimentation with diets and health practices. Vegetarianism has also been a religious practice for some Americans, including the Seventh-day Adventists, whose lacto-ovo vegetarian diets have been studied for their health benefits. Vegetarianism has been steadily gaining acceptance as an alternative to the meat-and-potatoes bias of the traditional U.S. diet. In 2009, Vegetarian Resource Group performed a poll that showed that 3% of the adult U.S. population identified themselves as vegetarians.

Several factors contribute to the interest in vegetarianism in the United States. Outbreaks of **food poisoning** from meat products, as well as increased concern over the additives in meat such as hormones and **antibiotics**, have led some people and professionals to question meat's safety. There is also an increased awareness of the questionable treatment of farm animals in factory farming. However, the growing health consciousness of Americans is probably the major reason for the surge in interest in vegetarianism. **Nutrition** experts have built up convincing evidence that there are major problems with the conventional U.S. diet, which is centered around meat products that are high in cholesterol and saturated fat and low in fiber. Heart disease, cancer, and diabetes, which cause 68% of all deaths in the United States, are all believed to be influenced by this diet. Nutritionists have repeatedly shown in studies that a healthy diet consists of plenty of fresh vegetables and fruits, complex carbohydrates, such as whole grains, and foods that are high in fiber and low in cholesterol and saturated fat. Vegetarianism, a diet that fulfills all these criteria, has become part of many healthy lifestyles. In alternative medicine, vegetarianism is a cornerstone dietary therapy, used in **Ayurvedic medicine**, **detoxification** treatments, macrobiotics, the Ornish diet for heart disease, and in therapies for many chronic conditions.

Preparations

Some people, particularly those with severe or chronic conditions such as heart disease or cancer, may be advised by a health practitioner to become vegetarian suddenly. For most people, nutritionists recommend that a vegetarian diet be adopted gradually to allow people's bodies and lifestyles time to adjust to new eating habits and food intake.

Some nutritionists have designed transition diets to help people become vegetarian in stages. Many Americans eat meat products at nearly every meal, and the first stage of a transition diet is to substitute just a few meals a week with wholly vegetarian foods. Then particular meat products can be slowly reduced and eliminated from the diet and replaced with vegetarian foods. Red meat can be reduced and then eliminated, followed by pork, poultry, and fish. For those wishing to become pure vegetarians or vegans, the final step would be to substitute eggs and dairy products with other nutrient-rich foods. Individuals should be willing to experiment with transition diets, and should have patience when learning how combine vegetarianism with social activities such as dining out.

The transition to vegetarianism can be smoother for those who make informed choices with dietary practices. Sound nutritional guidelines include decreasing the intake of fat, increasing fiber, and emphasizing fresh fruits, vegetables, legumes, and whole grains in the diet while avoiding processed foods and sugar. Everyone can improve their health by becoming familiar with recommended dietary and nutritional practices, such as reading labels and understanding basic nutritional concepts such as daily requirements for calories, protein, fat, and nutrients. Would-be vegetarians can experiment with meat substitutes, foods that are high in protein and essential nutrients. Thanks to the growing interest in vegetarianism, many meat substitutes are now readily available. Tofu and tempeh are products made from soybeans that are high in protein, **calcium**, and other nutrients. There are "veggie-burgers" that can be grilled like hamburgers, and vegetarian substitutes for turkey and sausage with surprisingly authentic textures and taste. There are many vegetarian cookbooks on the market as well.

A set of guidelines for North American vegetarian diets, updated for 2004, is available from the American Dietetic Association and the Dietitians of Canada. The new guidelines are intended to promote variety within vegetarian diets and to meet the needs of different stages in the life cycle as well as incorporate the most recent findings of medical research.

One remaining drawback to the widespread practice of vegetarianism is the unpleasant taste or smell of many vegetables. A number of phytonutrients have a bitter, astringent, or acrid taste that they impart to products made from vegetables that contain them. Some experts think that people tend to reject such strong-smelling or bitter-tasting vegetables as turnips, cabbage, brussels sprouts, or broccoli because humans have been programmed in the course of evolution to associate bitter taste with poisonous plants. It is increasingly recognized that the major barrier to dietary change for the sake of health is taste. One recommendation for improving the taste appeal of vegetarian diets is more frequent use of spices. In addition to pleasing the human palate, spices derived from plants have been shown to have chemoprotective effects, boosting the immune system, reducing inflammation, and fighting harmful bacteria and viruses.

Precautions

In general, a well-planned vegetarian diet is healthful and safe; in the summer of 2003, a position paper endorsed by the American Dietetic Association and the Dietitians of Canada referred to vegetarian diets as "healthful, nutritionally adequate, and [able to] provide health benefits in the prevention and treatment of certain diseases." However, vegetarians, and particularly vegans who eat no animal products, need to be aware of particular nutrients that may be lacking in non-animal diets. These are amino acids, vitamin B_{12}, vitamin D, calcium, iron, zinc, and essential fatty acids. Furthermore, pregnant women, growing children, and those with health conditions have higher requirements for these nutrients.

Vegetarians should be aware of getting *complete protein* in their diets. A complete protein contains all of the essential amino acids, which are the building blocks for protein essential to the diet because the body cannot make them. Meat and dairy products generally contain complete proteins, but most vegetarian foods such as grains and legumes contain incomplete proteins, lacking one or more of the essential amino acids. However, vegetarians can easily overcome this by combining particular foods in order to create complete proteins. For instance, beans are high in the amino acid lysine but low in tryptophan and methionine, but rice is low in lysine and high in tryptophan and methionine. Thus, combining rice and beans makes a complete protein. In general, combining legumes such as soy, lentils, beans, and peas with grains like rice, wheat, or oats forms complete proteins. Eating dairy products or nuts with grains also makes proteins complete. Oatmeal with milk on it is complete, as is peanut butter on whole wheat bread. Proteins do not necessarily need to be combined in the same meal, but generally within four hours.

Getting enough vitamin B_{12} may be an issue for some vegetarians, particularly vegans, because meat and dairy products are the main sources. Vitamin supplements that contain vitamin B_{12} are recommended. Spirulina, a nutritional supplement made from algae, is also a vegetarian source, as are fortified soy products and nutritional yeast.

Vitamin D can be obtained by **vitamins**, fortified foods, and sunshine. Calcium can be obtained in enriched tofu, seeds, nuts, legumes, dairy products, and dark green vegetables including broccoli, kale, spinach, and collard greens. Iron is found in raisins, figs, legumes, tofu, whole grains (particularly whole wheat), potatoes, and dark green leafy vegetables. Iron is absorbed more efficiently by the body when iron-containing foods are eaten with foods that contain vitamin C, such as fruits, tomatoes, and green vegetables. Zinc is abundant in nuts, pumpkin seeds, legumes, whole grains, and tofu. For vegetarians who do not eat fish, getting enough omega-3 essential fatty acids may be an issue, and supplements such as flaxseed oil should be considered, as well as eating walnuts and canola oil.

Vegetarians do not necessarily have healthier diets. Some studies have shown that some vegetarians consume large amounts of cholesterol and saturated fat. Eggs and dairy products contain cholesterol and saturated fat, while nuts, oils, and avocados are vegetable sources of saturated fat. To reap the full benefits of a vegetarian diet, vegetarians should be conscious of cholesterol and saturated fat intake. Vegetarians may also consider buying organic foods, which are grown without the use of synthetic chemicals, as another health precaution.

Research and general acceptance

A vegetarian diet has many well-documented health benefits. It has been shown that vegetarians have a higher life expectancy, as much as several years, than those who eat a meat-centered diet. The U.S. Food and Drug Administration (FDA) has stated that data has shown vegetarians to have a strong or significant probability against contracting obesity, heart disease, lung cancer, **colon cancer**, **alcoholism**, hypertension, diabetes, gallstones, gout, kidney stones, and ulcers. However, the FDA also points out that vegetarians tend to have healthy lifestyle habits, so other factors may contribute to their increased health besides diet alone.

KEY TERMS

Cholesterol—A steroid fat found in animal foods that is also produced in the body from saturated fat for several important functions. Excess cholesterol intake is linked to many diseases.

Complex carbohydrates—Complex carbohydrates are broken down by the body into simple sugars for energy, are found in grains, fruits and vegetables. They are generally recommended in the diet over refined sugar and honey, because they are a more steady source of energy and often contain fiber and nutrients as well.

Legume—Group of plant foods including beans, peas, and lentils, which are high in protein, fiber, and other nutrients.

Organic food—Food grown without the use of synthetic pesticides and fertilizers.

Saturated fat—Fat that is usually solid at room temperature, found mainly in meat and dairy products but also in vegetable sources such as some nuts, seeds, and avocados.

Tempeh—A fermented cake of soybeans and other grains; it is a staple food in Indonesia.

Tofu—A soft cheeselike food made from curdled soybean milk.

Unsaturated fat—Fat found in plant foods that is typically liquid (oil) at room temperature. They can be monounsaturated or polyunsaturated, depending on the chemical structure. Unsaturated fats are the most recommended dietary fats.

A vegetarian diet, as prescribed by Dr. Dean Ornish, has been shown to improve heart disease and reverse the effects of **atherosclerosis**, or hardening of the arteries. It should be noted that Dr. Ornish's diet was used in conjunction with **exercise**, **stress reduction**, and other holistic methods. The Ornish diet is lacto-ovo vegetarian, because it allows the use of egg whites and non-fat dairy products.

Vegetarians have a resource of statistics in their favor when it comes to presenting persuasive arguments in favor of their eating habits. Vegetarians claim that a vegetarian diet is a major step in improving the health of citizens and the environment. Americans eat over 200 lbs (91 kg) of meat per person per year. The incidence of heart disease, cancer diabetes, and other diseases has increased along with a dramatic increase in meat consumption during the past century. Many statistics show significantly smaller risks for vegetarians contracting certain conditions. The risks of women getting **breast cancer** and men contracting prostrate cancer are nearly four times as high for frequent meat eaters as for those who eat meat sparingly or not at all. For heart attacks, American men have a 50% risk of having one, but the risk drops down to 15% for lacto-ovo vegetarians and to only 4% for vegans. For cancer, studies of populations around the world have implied that plant-based diets have lower associated risks for certain types of cancer.

Vegetarians claim other reasons for adopting a meat-free diet. One major concern is the amount of pesticides and synthetic additives such as hormones that show up in meat products. Chemicals tend to accumulate in the tissue of animals that are higher in the food chain, a process called *bioaccumulation*. Vegetarians, by not eating meat, can avoid the exposure to these accumulated toxins, many of which are known to influence the development of cancer. One study showed that DDT, a cancer-causing pesticide, was present in significant levels in mother's milk for 99% of American women, but only 8% of vegetarian women had significant levels of the pesticide. Women who eat meat had 35 times higher levels of particular pesticides than vegetarian women. The synthetic hormones and antibiotics added to U.S. cattle has led some European countries to ban U.S. beef altogether. The widespread use of antibiotics in livestock has made many infectious agents more resistant to them, making some diseases harder to treat.

Vegetarians resort to ethical and environmental arguments as well when supporting their food choices. Much of U.S. agriculture is dedicated to producing meat, which is an expensive and resource-depleting practice. It has been estimated that 1.3 billion people could be fed with the grain that the United States uses to feed livestock, and **starvation** is a major problem in world health. Producing meat places a heavy burden on natural resources, as compared to growing grain and vegetables. One acre of land can grow approximately 40,000 lbs (18,000 kg) of potatoes or 250 lbs (113 kg) of beef, and it takes 50,000 gal (200,000 l) of water to produce 1 lb (0.45 kg) of California beef but only 25 gal (100 l) of water to produce 1 lb (0.45 kg) of

wheat. Half of all water used in the United States is for livestock production. Vegetarians argue that the consumption of beef in the United States may also be contributing to global warming, by the large amounts of fossil fuels used in its production. The South American rainforest is being cleared to support U.S. beef consumption, as the United States yearly imports 300 million lbs (136 million kg) of meat from Central and South America. The production of meat has been estimated as causing up to 85% of the loss of topsoil of U.S. farmlands. A German researcher in the field of nutrition ecology has summarized the environmental benefits of vegetarian diets, saying, "Research shows that vegetarian diets are well suited to protect the environment, to reduce pollution, and to minimize global climate changes."

Despite the favorable statistics, vegetarianism does have its opponents. The meat industry in the United States is a powerful organization that has spent millions of dollars over decades advertising the benefits of eating meat. Vegetarians point out that life-long eating habits are difficult to change for many people, despite research showing that vegetarian diets can provide the same nutrients as meat-centered diets.

Vegetative state

Definition

A coma-like state characterized by open eyes and the appearance of wakefulness is defined as vegetative.

Description

The vegetative state is a chronic or long-term condition. This condition differs from a persistent vegetative state (PVS, a state of **coma** that lacks both awareness and wakefulness) since patients have awakened from coma, but still have not regained awareness. In the vegetative state patients can open their eyelids occasionally and demonstrate sleep-wake cycles. They also completely lack cognitive function. The vegetative state is also called coma vigil.

Causes and symptoms

The vegetative state can be caused by:

- cardiac arrest
- prolonged and profound hypoglycemia (an abnormal and severe decrease in blood sugar)

- carbon monoxide poisoning
- head injury
- brain hemorrhage
- compression of the brainstem
- tumors
- bilateral hemispheric demyelination (a loss of nerve cells)
- injury of the brain following infections (meningitis or encephalitis)
- neurodegenerative diseases
- anencephaly (an abnormality of the brain and skull)
- diffuse nerve cell injury

Patients in a vegetative state apparently have functioning of a special area in the brain called the reticular activating system (RAS) responsible for sleep-wake cycles. The connections that integrate more complex abilities such as awareness are interrupted. Patients in the vegetative state can open and close eyes spontaneously. They may appear to track or follow objects with their eyes. Patients may chew and swallow food placed in the mouth. The vegetative patient does not respond to sound, hunger, or **pain**. Patients cannot obey verbal commands and lack local motor responses. Additionally, these patients cannot talk in comprehendible terms and they may become noisy, restless, and hypermobile. These patients are in a state of arousal but completely lack awareness.

Diagnosis

Diagnosis of vegetative state depends on the primary cause of brain dysfunction. A comprehensive history and neurological examination, neuroimaging studies, and chemical analysis of the blood are essential. Additionally, special tests such as cerebrospinal fluid (CSF, the fluid that bathes and nourishes the brain and spinal cord) analysis and **electroencephalography** (EEG analyzes the electrical activity within the brain) may be indicated to establish a diagnosis.

Treatment

Treatment is directed to presenting symptoms and patient needs. Patients require constant monitoring and assistance with feeding, hydration hygiene, assisted movement (to help prevent ulcers and **blood clots** in the legs), and elimination of waste products.

Alternative treatment

There is no known alternative treatment for vegetative patients.

KEY TERMS

Cognitive—The ability (or lack of) to think, learn, and memorize.

Hypermobility—Increased movement of joints.

Prognosis

The prognosis is generally poor and the condition can persist chronically.

Prevention

There is no known prevention since this state can occur as a result of unavoidable situations such as an accident, tumor, and bleeding or genetic abnormality.

Velopharyngeal insufficiency

Definition

Velopharyngeal insufficiency is the improper closing of the velopharyngeal sphincter (soft palate muscle) during speech characterized by an acute nasal quality of the voice.

Description

At the back of the mouth is a circle of structures that include the tonsils, the tongue, and the palate. During speech, this apparatus must close off the nose for proper articulation of the explosive consonants "p," "b," "g," "t," and "d." If it does not close, there is a snort sound produced through the nose. Improper function of this structure also produces a nasal tone to the voice.

KEY TERMS

Adenoids—Lymph glands just above the tonsils and the palate.

Cleft palate—Congenital defect marked by a split in the roof of the mouth.

Nasopharyngoscopy—A diagnostic procedure that examines the nasal passageways and pharynx with an instrument outfitted with an optical system.

Pharynx—A canal located between the mouth cavity and the esophagus.

Tonsillectomy—Surgical removal of the tonsils.

Tonsils—Lymph glands in the throat, just behind the back teeth.

Causes and symptoms

There are three main causes for this defect:

- Cleft palate is a congenital condition, producing a defect in the palate that allows air to escape upward during speech.
- If tonsil and adenoid surgery is done improperly, velopharyngeal insufficiency may result. The occurrence rate is approximately one in every 2,000–3,000 tonsillectomies.
- Nerve or muscle disease may paralyze the muscles that operate the velopharyngeal sphincter.

The primary symptom is the speech impediment. Some people develop a change in their speaking pattern or a series of facial grimaces to try to overcome the difficulty. If the condition is acute, regurgitation through the nose may occur.

Diagnosis

Examination of the velopharyngeal sphincter through ultrasound scans, fiber-optic nasopharyngoscopy, and videofluoroscopy will reveal the extent of velopharyngeal insufficiency. Speech and velopharyngeal sphincter movement are compared to make the diagnosis.

Treatment

Velopharyngeal insufficiency is treated with a combination of surgery and **speech therapy**. There are several surgical procedures that can be performed to correct the physical malfunction. They include:

- Pharyngeal flap procedure that moves the skin flap from the pharynx to the soft palate.
- Palatal push-back that separates the hard and soft palate in order to lengthen the soft palate.
- Pharyngoplasty that lengthens the soft palate by turning the pharyngeal skin flaps.
- Augmentation pharyngoplasty that inserts an implant into the pharyngeal wall to enlarge it, thus narrowing the velopharyngeal opening.
- Velopharyngeal sphincter reconstruction.

Prognosis

The combination of surgery to correct the insufficiency and speech therapy to retrain the voice successfully alleviate velopharyngeal insufficiency.

Vena cava filter

Definition

A vena cava filter is a device inserted into a major vein to prevent a blood clot from entering the lungs.

Purpose

The purpose of a vena cava filter is to prevent a blood clot from potentially traveling to the lungs. A thrombus clot traveling to the lungs is called a **pulmonary embolism** (PE). A thrombus in the deep venous system (the part of the circulation that brings blood back to the heart) represents a disorder of normal hemostasis (the normal clotting of blood).

Insertion of a vena cava filter is indicated for patients who:

- cannot receive medications that can dissolve the clot (anticoagulation therapy)
- have a thrombus in a deeply situated vein
- experiance complication of anticoagulation therapy such as bleeding

- experiance failure of anticoagulation therapy to prevent pulmonary embolism
- have an embolus in the lungs (pulmonary embolectomy) removed
- have a recurrent embolism while receiving adequate medications
- have significant bleeding complications during anticoagulation

Precautions

There are no significant precautions concerning insertion of a vena cava filter. The devices are usually effective and short-term complications are unusual.

Description

Vena cava filters are usually inserted in to prevent PE caused by a thrombosis in a deep vein (DVT). Approximately 60% of patients who die in a hospital have evidence of PE during **autopsy**. The incidence (number of new cases) of DVT is highest for patients undergoing surgical repair of a fractured hip. However, DVT is common in both surgical and medical patients. DVT is found in 29–33% of patients in medical intensive care units (MICU) and in 27–40% of patients with a **heart attack** (myocardial infarction). Vena cava filters are placed to prevent thrombi from entering the lungs. There is currently a new type of filter called the Kim-Ray-Greenfield filter.

Preparation

Insertion of a vena cava filter is an invasive procedure. The patient is prepared for this procedure using standard surgical protocols. The VCF is commonly implanted in the jugular vein in the neck or the femoral vein in the groin. The procedure is generally well tolerated.

Aftercare

This depends on the patient's health status and recommendations for continued care.

Risks

Many patients have died from PE even with a vena cava implantation. Use of a VCF is primarily indicated if there are contraindications for anticoagulation therapy. VCF can increase a patient's susceptibility for developing recurrent DVT.

Normal results

The patient progresses well and prevention of large emboli that can cause a PE is successful.

KEY TERMS

Embolus—An embolus (or emboli the plural form) is a blood clot that has detached from its site of origin and travels to the lungs (pulmonary artery), where it can rupture the artery, causing death.

Pulmonary embolism—A traveling thrombus that has lodged in the pulmonary artery.

Thrombus—A thrombus (or thrombi the plural form) is a blood clot that can form in a deeply situated vein.

Abnormal results

The desired effect is not accomplished and the patient develops a PE resulting in **death**.

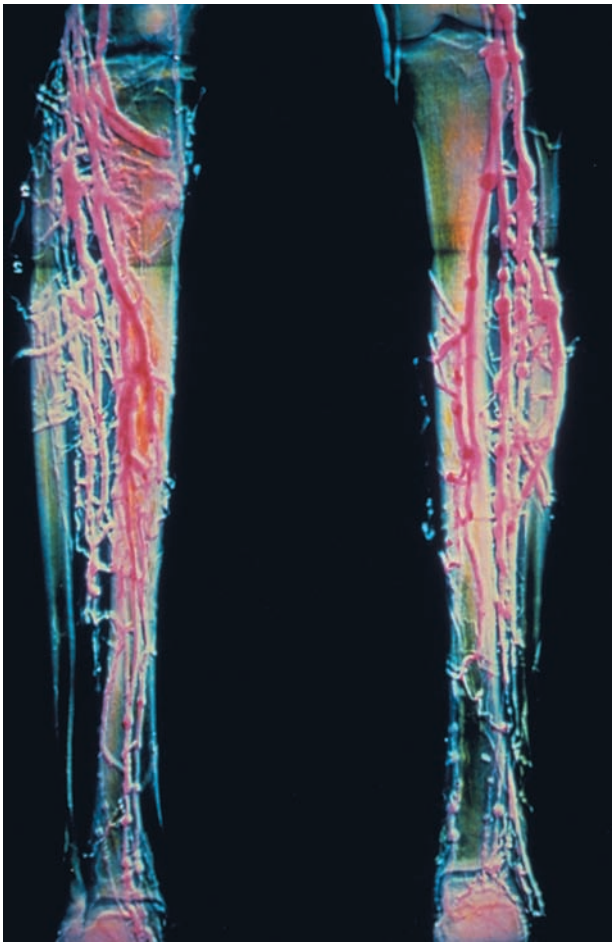
Venography

Definition

Venography is an x-ray test that provides an image of the leg veins after a contrast dye is injected into a vein in the patient's foot.

Purpose

Venography is primarily performed to diagnose **deep vein thrombosis** (a condition that can lead to **pulmonary embolism**). It is the standard procedure used to detect this type of disorder. Venography also can be used to distinguish **blood clots** from obstructions in the veins, to evaluate congenital vein problems, to see how the deep leg vein valves are working, and to identify a vein for arterial bypass grafting.



A venographic image of a patient's legs with varicose veins. *(Custom Medical Stock Photo, Inc. Reproduced by permission.)*

Precautions

Venography usually is not performed in patients with kidney (renal) problems.

Description

Venography (also called phlebography, ascending contrast phlebography, or contrast venography) is an invasive diagnostic test that provides a constant image of leg veins on a fluoroscope screen. Venography identifies the location, extent, and degree of attachment of the blood clots and enables the condition of the deep leg veins to be assessed. It is especially useful when there is a strong suspicion of deep vein thrombosis but non-invasive tests have failed to identify the disease.

Venography is the most accurate test for detecting deep vein thrombosis. It is nearly 100% sensitive and specific in making this diagnosis (pulmonary **embolism** is diagnosed in other ways). Accuracy is crucial since deep vein thrombosis can lead to pulmonary embolism, a condition that can be fatal.

Venography is not used often, however, because it is painful, expensive, exposes the patient to a fairly high dose of radiation, and can cause complications. In about 5% of cases, there are technical problems in conducting the test. In addition, the test is less accurate in diagnosing problems below the knee. Venography takes between 30–45 minutes and can be done in a physician's office, outpatient center, or a hospital.

In 2003, a report said that computed tomography (CT) scanning could be used to diagnose pulmonary embolism and deep veinous thrombosis in one examination. By combining CT **angiography** and CT venography, researchers could look for both conditions in one procedure with high-speed CT scanners. The procedure was quick and delivered a reduced radiation dose. However, it has not become accepted as a replacement for traditional venography and is only preferred if the patient is clinically stable and requires immediate diagnosis and treatment.

During the procedure, the patient lies on a tilting x-ray table. The area where the catheter will be inserted will be shaved, if necessary, and cleaned. Sometimes a local anesthetic is injected to numb the skin at the site of the insertion. A small incision may be required to make a point for insertion. The catheter is inserted and the contrast solution (or dye) is slowly injected. Injection of the dye causes a warm, flushing feeling in the leg that may spread through the body. The contrast solution also may cause slight **nausea**. About 18% of patients experience discomfort from the contrast solution.

KEY TERMS

Contrast solution—A liquid dye injected into the body that allows veins to be seen by x rays. Without the dye, the veins could not be seen on x rays.

Deep vein thrombosis—The development or presence of a blood clot in a vein deep within the leg. Deep vein thrombosis can lead to pulmonary embolism.

Invasive—A diagnostic test that invades healthy tissue; in the case of venography, through an incision in a healthy vein.

Pulmonary embolism—An obstruction of a blood vessel in the lungs, usually due to a blood clot, that blocks a pulmonary artery. Pulmonary embolism can be very serious and in some cases is fatal.

In order to fill the deep venous system with dye, a tight band (or tourniquet) may be tied around the ankle of the foot the dye is injected into or the lower extremities may be tilted. The patient is asked to keep the leg still. The doctor also observes the movement of the solution through the vein with a fluoroscope. At the same time, a series of x rays are taken. When the test is finished, fluid is injected to clear the dye from the veins, the catheter is removed, and a bandage is applied over the site of the injection.

Preparation

Fasting or drinking only clear liquids is necessary for four hours before the test. However, sometimes the test is done in an emergency even if the patient has eaten. The contrast solution contains iodine, to which some people are allergic. Patients who have **allergies** or hay fever, or have had a bad reaction to a contrast solution, should tell the doctor. A sedative, such as diazepam (Valium), may be prescribed to help the patient relax.

Aftercare

Patients should drink large amounts of fluids to flush the remaining contrast solution from their bodies. The area around the incision will be sore for a few days. If there is swelling, redness, **pain**, or fever, the doctor should be notified. Pain medication may be needed. In most cases, the patient can resume normal activities the next day.

Risks

Venography also can cause complications such as phlebitis, tissue damage, and the formation of deep vein thrombosis in a healthy leg. A rare side effect in up to 8% of cases is a severe allergic reaction to the dye. This usually happens within 30 minutes after injection of the dye and requires medical attention.

Normal results

Normal venography results show proper blood flow through the leg veins.

Abnormal results

Abnormal venography results show well-defined filling defects in veins. Findings include:

- blood clots
- consistent filling defects
- an abrupt end of a test dye column
- major deep veins that are unfilled
- dye flow that is diverted

These results confirm a diagnosis of deep vein thrombosis.

Lori De Milto
Teresa G. Odle

Venous access

Definition

Venous access introduces a needle or catheter into a vein. The venous access can then be used to withdraw blood, administer fluids or blood products, infuse parenteral **nutrition**, and/or administer medications.

Purpose

Venous access is necessary for fluid administration, medication administration, and obtaining blood

for chemical analysis. Sites for access include veins located in the peripheral arms or legs, scalp, neck, and bone. Large central veins such as the subclavian vein may also be used to initiate venous access.

Venous access in children may pose special problems since finding appropriate veins and **immobilization** during the procedure may be difficult but essential. For complicated procedures **sedation** may be indicated. Venous access can be performed during emergency situations, and can be performed for outpatients, inpatients, and those who require long term administration of blood products or medication such as **chemotherapy**.

KEY TERMS

Cannula—Insertion of a tube.

Catheterization—The process of inserting a tubular instrument into a body cavity to permit passage of fluid.

Phlebitis— Inflammation of a vein.

Pneumothorax—The presence of air in the cavity that surrounds the lungs.

Description

For peripheral venipuncture the common site is usually a vein in the arm (the anticubital fossa located on the opposite side of the elbow) or on the flat bony area of the hand (dorsum of the hand). Scalp veins are accessible in infants under one year of age. The selected vein should be long and straight for needle accommodation. It should be identified by straightness, lack of pulsation (characteristic of an artery), and filling with blood from above (arteries fill from below). Internal jugular catheterization is performed in the neck using special bone and muscle landmarks. The external jugular vein can be cannulized by immobilizing, tilting and rotating the head. The subclavian approach is a complicated procedure and emergency access can be performed if attempts to access a vein in other areas have failed. Intraosseous venous access is usually accomplished through a leg bone. Catheters and subcutaneously implanted ports placed in the front of the chest (anterior chest wall) and other anatomic locations can accomplish long-term venous access as can peripherally inserted central catheters (PICC lines).

Precautions

There are no major precautions for access during emergency procedures. The main concern during an emergency is to secure a portal of entry to infuse potentially life-saving medications and fluids. For all methods of access the main precautionary measures include attention to accurate procedures. Proper procedures are necessary to minimize the possibility of infection, **embolism**, phlebitis, or destruction of neighboring tissue.

Preparation

For peripheral vein access in the arm, a tourniquet is applied a few inches over the puncture site. The skin over the puncture site is cleansed with an alcohol pad or similar cleansing product. The needle is inserted and either blood is drawn and the needle is removed or a catheter is inserted to place an intravenous line. Internal jugular vein catheterization is accomplished by extending the patient's head over the edge of a bed, table or cart and rotating the head away from the intended puncture site. Immobilizing the head and extending it 15–20 degrees over the edge of a bed or cart and rotating away from the puncture site can cannulize the external jugular vein. The subclavian vein access is a complicated procedure and may require sedation and special positioning (Trendelenburg). A towel should be place in the back of the area. The skin should be cleansed and the puncture site anesthetized. For the femoral approach the leg is externally rotated. The artery should be felt and along with specific anatomical landmarks the vein can be localized. The skin should be cleaned and anesthetized. During venous cutdown a large vein near the anklebone is careful dissected away from underlying tissues. The area must be properly cleaned and anesthetized prior to making an incision. A catheter is inserted and secured in place with sutures.

Aftercare

For simple procedures such as peripheral venous access, applying simple pressure (to stop bleeding) once the catheter is removed and then a bandage may be sufficient. Aftercare of more complicated venous access procedures varies depending on the type of device placed and the location of the device.

Risks

For access into a peripheral vein, care must be taken not to puncture both sides of the vein. After removal of the needle or catheter, pressure should be applied over the puncture site to prevent unwanted bleeding. Access utilizing a scalp vein should be performed with care by experienced clinicians only to avoid hematoma formation (localized blood clot),

accidental puncture of an artery, or infection. Access into the internal jugular vein in the neck can cause laceration of an artery or nerve. This procedure can also cause hematoma (blood clot) formation, damage to local nerves within the area, **pneumothorax**, or misplaced catheterization. Venous access into the external jugular vein can cause hematoma or placement of a venous access device outside the thorax. Subclavian vein access can cause air to enter a vein (resulting in an air embolus) or pneumothorax. Cannulation of the femoral vein in the groin area can cause infection or **thrombophlebitis**. Intraosseous venous access, commonly performed in a leg bone, can cause hematomas, infection, or damage to bone marrow. This procedure should not be performed if the attempts in one leg are unsuccessful, the skin over the legs is diseased (from a burn or infection), or there is a broken leg bone or bone disease. Venous cutdown can cause infection, loss of the catheter in the vein, phlebitis, or nerve damage.

Venous insufficiency

Definition

Venous insufficiency is described as abnormal blood flow through veins that can cause local damage, damage to affected legs, or **death**.

Description

Syndromes related to venous insufficiency are caused by valve incompetence. Venous insufficiency is a chronic (long term) condition. The number of new and existing cases is dependent on age and gender. Some patients may have a positive family history. Usually older persons and females are more commonly affected. Deep situated and superficial veins can be affected. **Cancer** obstructing veins in the pelvis area can cause superficial venous insufficiency. Deep venous insufficiency is commonly caused by **thrombophlebitis**, causing obstruction of valves that regulate blood flow in veins. Small veins that have been occluded by a thrombosis may re-canalize (opening up new channels to re-direct blood flow). These re-canalized veins are inadequate and cannot correct the impairment of flow. However, larger veins may still remain occluded. When a thrombosis occurs the valves that regulate venous blood flow become thickened and incompetent, rendering them incapable of regulating back flow of blood. This valvular incompetence will cause an increase in the presence within veins (venous **hypertension**). Venous hypertension is responsible for most of the symptoms associated with venous disease. Superficial veins can become dilated causing **varicose veins** (veins that bulge and seem tortuous). Leg ulcers can be severe and are responsible for 100,000 cases of disability in the United States alone.

Causes and symptoms

The symptoms of chronic venous insufficiency can be subjective and objective. Subjective symptoms include throbbing, cramping, burning sensations, and leg **fatigue**. Patients can also develop chronic leg ulcers that may not heal. Varicose veins in the legs can bleed (since veins are delicate structures with thin walls) and cause death. Patients often develop fluid retention (**edema**) in the affected limb. Skin changes can occur and affected areas can become thin, shiny, discolored (blue-purple), and atrophic. The skin usually becomes thick and tough.

Diagnosis

There are several techniques used to diagnose venous disease. Electrical impedance plethysmography (IPG) provides a functional evaluation for outflow obstruction ultrasound (a machine that transmits sound waves) studies can visualize the venous system in certain areas. Another technique called duplex scanning can measure velocity within a vein.

KEY TERMS

Atrophic—A wasting of cells and tissues.

Thrombophlebitis—Venous inflammation with formation of a thrombus.

Thrombus—A clot in the cardiovascular system (the system that circulates blood throughout the body).

Treatment

Periodic elevation of legs and bed rest can help with leg swelling. Patients are advised to avoid prolonged periods of standing or sitting. Wearing compression stockings can also reduce swelling of the leg. Mild skin infections can be treated with compresses, **steroids**, and, if infection is present, with **antibiotics**. Ulcerations can be treated with compresses, possible surgery, special ointments, and a semi-rigid boot that helps improve blood flow. Varicose veins can be treated with elastic stockings. About 15–20% of patients require surgery, but only after careful evaluation and specialized testing confirms a beneficial value.

Prognosis

The prognosis is variable and depends on the progression of disease, extent of damage, and the presence of other diseases, which may affect the cardiovascular system.

Prevention

Persons who have a strong family history, evidence of disease, and/or those who stand on their legs many hours daily should discuss the option of elastic stocking with their primary clinician.

Ventricular aneurysm

Definition

Ventricular aneurysm is a complication of a **heart attack** (myocardial infarction). It is a ballooning of a section of a blood vessel in the heart that first appears several days or weeks after an acute myocardial infarction.

Description

A myocardial infarction occurs when a section of the heart wall is deprived of blood and dies (undergoes necrosis, or tissue **death**, and scarring). The heart wall is mainly muscle. It has two ventricles, the right and left ventricles, which pump blood to and from the lungs, and to the body. When part of the heart muscle dies, pumping power from that part of the wall is lost. After a myocardial infarction, the part of the heart wall that did not die must continue pumping blood and compensate for the dead muscle.

Ventricular aneurysm is one of the complications that follow a myocardial infarction.

An aneurysm is the outward swelling, or ballooning, of a blood vessel at a weak spot in the wall of the blood vessel. In the case of ventricular aneurysm, the aneurysm occurs in the wall of the heart at the spot where the myocardial infarction occurred. A scar usually forms in the area of the dead muscle tissue, and may eventually calcify. Ventricular aneurysms generally do not rupture. The left ventricle is involved in most cases of ventricular aneurysm.

Causes and symptoms

The principle symptom of a ventricular aneurysm is cardiac insufficiency, a condition in which not enough blood is being pumped to the body. Ventricular aneurysm is usually found after a large infarction in the muscle wall of a ventricle. Ventricular aneurysm is seldom seen immediately after a myocardial infarction. It takes several days or weeks to several months to develop. Frequently, recurrent ventricular irregular heartbeats (**arrhythmias**) and low cardiac output result from the presence of a ventricular aneurysm. **Blood clots** (thrombi) may form on the inside wall of the aneurysm and produce systemic blood clots that get stuck in a blood vessel (embolisms), which could lead to **stroke** or an ischemic leg (a usually painful condition in which lack of blood circulation leads to reduced function).

KEY TERMS

Arrhythmia—A disturbance in the beating pattern of the heart.

Myocardial infarction—Commonly known as a heart attack, a myocardial infarction occurs when a part of the heart muscle is deprived of blood and dies.

Diagnosis

A number of signs may indicate ventricular aneurysm, including an abnormal precordial impulse in the heartbeat, persistent elevation of the S-T segment of an electrocardiogram, and a characteristic bulge seen on the heart when x rayed. The bulge is typically seen when the heart contracts, driving blood to the aorta, in the systolic phase of the heartbeat. Echolocation (**echocardiography** or ultrasound) can confirm the presence of an aneurysm. **Cardiac catheterization** may be performed to determine the extent of the aneurysm and the status of the coronary arteries. Stethoscopic examination reveals abnormal heart sounds, especially those associated with a backflow of blood from the left ventricle to the left atrium in systole or contraction beat (mitral regurgitation). This heart murmur is caused by the heart muscles no longer being able to properly operate the mitral valve.

Treatment

Most cases of ventricular aneurysm are treated by close medical follow-up and limiting patient activity. Surgical removal of the aneurysm is an option when persistent left ventricular failure or arrhythmia occurs, and the aneurysm is large. **Vasodilators**, **diuretics**, and **digoxin** are used to treat **heart failure**. **Anticoagulant drugs** are used to prevent the formation of blood clots. **Antiarrhythmic drugs** are used to treat heart arrhythmias.

Prognosis

Ventricular aneurysm occurs more frequently than is commonly thought. Based on postmortem examination, ventricular aneurysm occurs in as many as 15% of myocardial infarction cases. Patients with a large ventricular aneurysm in the left ventricle have a reduced survival rate. Many patients have mild symptoms which are not life-threatening. The survival rate is dependent on the function of the left ventricle.

Ventricular assist device

Definition

A ventricular assist device (VAD) is a mechanical pump used for temporary blood circulation support. It decreases the workload of the heart while maintaining adequate flow and blood pressure.

Purpose

A VAD is a temporary life-sustaining device. VADs can replace the left ventricle (LVAD), the right ventricle (RVAD), or both ventricles (BIVAD). They are used when the heart muscle is damaged and needs to rest in order to heal or when blood flow from the heart is inadequate. VADs can also be used as a bridge in patients awaiting **heart transplantation** or in patients who have rejected a transplanted heart.

Examples of patients who might be candidates for a VAD are those who:

- have suffered a massive heart attack
- cannot be weaned from heart-lung bypass after treatment with intravenous fluids, medications, and insertion of a balloon pump in the aorta
- have an infection in the heart wall that does not respond to conventional treatment
- are awaiting a heart transplant and are unresponsive to drug therapy and intravenous fluids
- are undergoing high-risk procedures to clear the blockages in a coronary artery

Although one in five people suffer left side ventricular failure, only a minority are candidates for VADs. To be considered for a VAD, patients must meet specific criteria concerning blood flow, blood pressure, and general health.

Precautions

Poor candidates for a VAD include those with:

- irreversible renal failure
- severe disease of the vascular system of the brain
- cancer that has spread (metastasized)

- severe liver disease
- blood clotting disorders
- severe lung disease
- infections that do not respond to antibiotics
- extreme youth or age

Description

There are four types of VADs, each appropriate for a different condition. Surgery to install a VAD is performed under **general anesthesia** in a hospital operating room. An incision is made in the chest, then catheters are inserted into the heart and the correct artery. The surgeon sutures the catheters in place, then attaches tubing to connect the catheters to the pump. The pump stays outside the body. Once it is turned on, blood flows out of the diseased ventricle and into the pump, then is returned to the correct blood vessel leaving the heart.

Preparation

Before the operation the patient meets with an anesthesiologist to determine any special conditions that will affect the administration of anesthesia. Standard preoperative blood and urine studies are performed, and the heart is monitored both before and during the operation with an electrocardiograph.

Aftercare

The patient is monitored in intensive care, with follow-up blood, urine, and neurological studies. Blood thinning medications are given to prevent blood clotting.

Except for those patients awaiting a heart transplant, patients are slowly and gradually weaned from the VAD. Even when patients no longer need the VAD, they will require supportive drug therapy and/or a balloon pump inserted in the aorta.

Risks

VAD insertion carries risks of severe complications. Bleeding from surgery is common and occurs in as many as 30–50% of patients. Other complications include the development of **blood clots**, partial **paralysis** of the diaphragm, **respiratory failure**, kidney failure, failure of the VAD, damage to the coronary blood vessels, **stroke**, and infection.

Sometimes when the left ventricle is supported, the right ventricle begins to need assistance. If VADs are inserted in both ventricles, the heart may become so dependent on their support that they cannot be removed.

KEY TERMS

Coronary blood vessels—The arteries and veins that supply blood to the heart muscle.

Diaphragm—The muscle that separates the chest cavity from the abdominal cavity.

Ventricle—The heart has four chambers. The right and left ventricles are at the bottom of the heart and act as the body's main pumps.

Normal results

Because conditions for which VADs are used vary widely and because of the high risks associated with VAD insertion, the outcome of surgery cannot be predicted.

Ventricular ectopic beats

Definition

A ventricular ectopic beat (VEB) is an extra heartbeat originating in the lower chamber of the heart. This beat, also called a premature ventricular contraction (PVC), occurs before the beat triggered by the heart's normal function.

Description

Ventricular ectopic beats are common and do not indicate a problem in people without heart disease. However, if a person has aortic stenosis, **heart failure**, or a previous **heart attack**, VEBs may be followed by **ventricular tachycardia** and fibrillation, which can lead to sudden **death**.

KEY TERMS

Angioplasty—A surgical procedure which dilates a narrowed or blocked part of an artery.

Aortic stenosis—A stiffening of the artery which carries blood from the heart to the body.

Beta-blockers—A class of medication used to block the cellular response to chemicals normally present in the body.

Coronary artery—The vessel which brings blood to the muscle of the heart.

Fibrillation—Rapid, uncoordinated quivering of the heart.

Heart failure—A term used when the heart is unable to pump enough blood to supply the needs of the body.

Causes and symptoms

Although the origin of a VEB is well documented, the exact cause or causes are not well understood. Some physicians believe the beat is caused by a trigger of specific origin, while other physicians believe the beat is random. Occasional ventricular ectopic beats occur in healthy people. If there is no evidence of heart disease, there is little or no danger to the individual.

A single ventricular ectopic beat has very little effect on the pumping ability of the heart and usually does not cause any symptoms. If a symptom is felt, it is the feeling of a strong or skipped beat, often described as a thump, kick, or flip-flop. Sometimes, the sensation is referred to as a fullness in the neck.

Diagnosis

Ventricular ectopic beats are easily seen on an electrocardiogram.

Treatment

If a person is otherwise healthy, the only treatment needed is to decrease **stress** and limit the use of alcohol and **caffeine**. Cold medicines, available without prescription, sometimes contain drugs (e.g., **decongestants**) that stimulate the heart and should be used with caution.

If symptoms are uncomfortable, or the pattern of VEBs indicates a problem, the physician may prescribe drug therapy. Beta-blockers are quite safe and are usually tried first.

A person who has a history of heart attack or heart disease, and is experiencing frequent or complex VEBs, is at greater risk of sudden death. Drug therapy with beta-blockers will be recommended. In addition, **angioplasty** or coronary artery bypass surgery may relieve any underlying coronary artery blockage and reduce the danger of sudden death.

Treatment with **antiarrhythmic drugs** can suppress VEBs, but they can also increase the risk of a fatal abnormal rhythm. Often, extensive electrophysiologic testing and risk evaluation will be done before this method of treatment is prescribed.

Prognosis

In healthy people, VEBs are inconsequential. If a person with heart disease is able to find an effective means of controlling ventricular ectopic beats, the outlook is good.

Prevention

Occasional ventricular ectopic beats in healthy people do not need to be prevented. People with a history of heart disease can usually control VEBs with medication.

Ventricular failure *see* **Heart failure**

Ventricular fibrillation

Definition

Ventricular fibrillation is a very rapid, uncoordinated, ineffective series of contractions throughout the lower chambers of the heart. Unless stopped, these chaotic impulses are fatal.

KEY TERMS

Atrial fibrillation—A condition in which the upper chambers of the heart quiver instead of contracting effectively.

Cardiopulmonary resuscitation (CPR)—Using rescue breathing and chest compressions to help a person whose breathing and heartbeat have stopped.

Cardioversion—An electrical shock delivered to the heart to restore a normal rhythm.

Electrocardiogram—A visual representation of the heart beat.

Heart failure—A term used when the heart is unable to pump enough blood to supply the needs of the body.

Hypoxia—Insufficient oxygen in the cells of the body.

Ischemic—Insufficient blood reaching the tissues.

Description

When the ventricles begin to quiver and do not employ coordinated contractions, the heart is said to be fibrillating. In this condition the ventricles cannot pump blood from the heart. Ventricular fibrillation (V-fib) is the worst kind of abnormal heart rhythm, and is a form of cardiac arrest. It involves the pumping of the lower chambers of the heart, while **atrial fibrillation** involves the upper chambers.

Causes and symptoms

Ventricular fibrillation often is associated with acute ischemic events (**ischemia** involves the deprivation of oxygenated blood to an area of tissue), and with chronic ischemic heart disease. It is frequently seen immediately following a **heart attack**. It also may develop during hypoxia, atrial fibrillation, or improper grounding of electrical devices. An extremely low level of potassium in the blood also can cause ventricular fibrillation.

The first, and usually the only, symptom of V-fib is sudden unconsciousness.

Diagnosis

When an individual suddenly collapses, the possibility of ventricular fibrillation should be considered immediately. A quick assessment usually shows no pulse or heartbeat. The diagnosis of ventricular fibrillation is confirmed with an electrocardiogram.

Treatment

Basic **life support** with standard **cardiopulmonary resuscitation** (CPR) must be started within a few minutes, followed as soon as possible with **cardioversion**. Cardioversion is an electric shock delivered to the heart to stop the fibrillating. Early **defibrillation** is the key to survival. If left untreated, irreversible brain damage, due to lack of oxygen to the brain, occurs after about five minutes. After the heart resumes its normal rhythm, medications are given to help maintain the rhythm.

Research continues into methods to deliver defibrillation as soon as possible to those experiencing ventricular fibrillation. One of the studies addressed in 2003 researched various clinical trials that implanted defibrillators into patients to prevent **sudden cardiac death**. The devices worked in many instances but more proof of their success was needed for widespread use.

Prognosis

Early and effective CPR may provide the time necessary for medical personnel to arrive with a defibrillator. If a defibrillator is able to promptly restore a normal rhythm, up to 25% of victims are able to leave the hospital without evidence of brain damage.

If ventricular fibrillation occurs in the hospital in conjunction with a heart attack, defibrillation has a 95% success rate. If shock and **heart failure** are present at the time, even with immediate defibrillation, only about 30% of those stricken are successfully restored to a normal heart rate.

Prevention

A healthy lifestyle to reduce the risk of heart diseases which lead to ventricular fibrillation is the best prevention. For people who have experienced an episode of V-fib, an internal cardioverter-defibrillator may prevent further episodes.

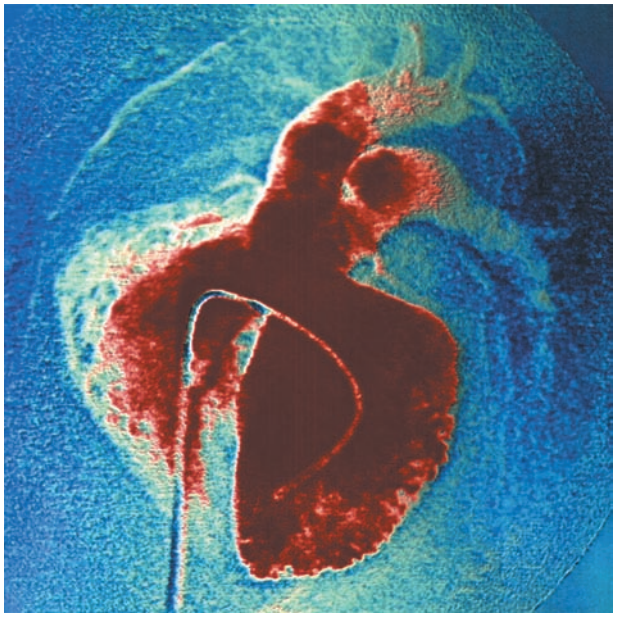
Ventricular septal defect

Definition

A ventricular septal defect is a hole in the wall of the heart (septum) that separates the left lower chamber (left ventricle) from the right lower chamber (right ventricle). The hole allows blood to flow from the left ventricle to the right ventricle instead of entering the aorta for distribution throughout the body. Ventricular septal defect is one of a group of heart problems found in newborn babies that are collectively called **congenital heart disease**.



An angiogram of a ventricular septal defect. This is a hole in the ventricular septum causing blood to flow from the left ventricle (right of image) to the right ventricle and to the lungs. The bent catheter at the center, which is used to take the angiogram, passes through the hole between the ventricles. *(Simon Fraser/SPL/Photo Researchers, Inc.)*

Description

The heart has four chambers. The two lower chambers are called ventricles and are responsible for pumping blood. The right ventricle pumps blood to the lungs and the left ventricle pumps blood throughout the body. If there is a hole in the septum that separates the two ventricles, blood from the left ventricle can enter the right ventricle. This blood recycles through the lungs before returning to the left ventricle. This results in less oxygenated blood reaching the body. If the hole is sufficiently large, the lack of oxygen being delivered to the body can cause severe problems, including **heart failure** and breathlessness. Approximately 0.7% of all babies have a congenital heart defect. Of these, 20% have a ventricular septal defect.

Causes and symptoms

Congenital heart defects are errors in the development of the heart structure. They occur early in the life of the embryo. There is no known cause of congenital heart defects. They can be associated with several diseases, such as German **measles** (rubella)and **Down syndrome**. Genetics does not seem to play a role in ventricular septal defect. People with a heart defect do not have an increased chance of passing it on to their children.

Symptoms result from a reduced amount of oxygen going to the body. Symptoms are proportional to the size of the defect. They may appear at any time in the life of the child. In cases where the hole in the septum is very small, few or no symptoms may appear and the child may develop normally. In cases where the ventricular septal defect is large, the newborn will shows signs of heavy breathing, sweating, and feeding difficulties. Children with this defect tire easily. Ventricular septal defect can also result in stunted growth resulting from insufficient oxygen being delivered to the growing body. Children with ventricular septal defect tend to suffer more frequent colds and **pneumonia**, and have a higher rate of inflammation and infection of the heart (**endocarditis**).

Diagnosis

The condition is first suspected based on observation of the child. The physician will listen to the heart with a stethoscope (auscultation) to detect a heart murmur. X rays, electrocardiogram (ECG), and **echocardiography** can all be used to evaluate ventricular septal defect.

KEY TERMS

Echocardiogram—An image of the heart produced by an instrument that uses sound waves to create image the heart.

Electrocardiogram—A graph of the heart's beating action.

Endocarditis—An inflammation of the interior lining of the heart that is frequently caused by infectious agents.

Treatment

Most small holes close without treatment. Often, as the child grows, the hole closes or becomes smaller. If the hole is large or fails to close, the child is usually treated with drugs. Holes that persist and are causing problems in development are corrected by open heart surgery. Usually, surgery is performed after one year of age, but before the child enters school. This allows time for a trial of drug therapy, which could potentially eliminate the need for surgery. The operation is generally safe.

Prognosis

Children with small septal defects tend to develop normally and without any effect on their ability to participate in physical activities. Surgery allows children with larger defects to live nearly normal lives.

Ventricular shunt

Definition

Ventricular shunt is a surgical procedure in which a tube is placed in one of the fluid-filled chambers inside the brain (ventricles). The fluid around the brain and the spinal column is called the cerebrospinal fluid. When infection or disease causes an excess of this cerebrospinal fluid in the ventricles, the shunt is placed to drain it and thereby relieve excess pressure.

Purpose

Ventricular shunt relieves **hydrocephalus**, a condition in which the ventricles are enlarged. In hydrocephalus, pressure from the cerebrospinal fluid usually increases. It may be caused by tumor of the brain or of the membranes covering the brain (meninges), infection of or bleeding into the cerebrospinal fluid, or inborn malformations of the brain. Symptoms of hydrocephalus may include **headache**, personality disturbances and loss of intellectual abilities (**dementia**), problems in walking, irritability, **vomiting**, abnormal eye movements, or a low level of consciousness.

Normal pressure hydrocephalus is associated with progressive dementia, problems in walking, and loss of bladder control (**urinary incontinence**). Even though the cerebrospinal fluid is not thought to be under increased pressure in this condition, it may also be treated by ventricular shunting.

Precautions

As with any surgical procedure, the surgeon must know about any medications or health problems that may increase the patient's risk. Because infections are both common and serious complications, **antibiotics** are often given before and after surgery.

Description

The ventricular shunt tube is placed to drain fluid from the ventricular system in the brain to the cavity of the abdomen or to the large vein in the neck (jugular vein). Therefore, surgical procedures must be done both in the brain and at the drainage site. The tubing contains valves to insure that fluid can only flow out of the brain and not back into it. The valve can be set at a desired pressure to allow cerebrospinal fluid to escape whenever the pressure level is exceeded.

A small reservoir may be attached to the tubing and placed under the scalp. This reservoir allows samples of cerebrospinal fluid to be removed with a syringe to check the pressure. Fluid from the reservoir can also be examined for bacteria, **cancer** cells, blood, or protein, depending on the cause of hydrocephalus. The reservoir may also be used to inject antibiotics for cerebrospinal fluid infection or **chemotherapy** medication for meningeal tumors.

Preparation

The diagnosis of hydrocephalus should be confirmed by diagnostic techniques that make images of the brain, such as computed tomography scan (CT scan) or **magnetic resonance imaging** (MRI), before

KEY TERMS

Cerebrospinal fluid—Fluid bathing the brain and spinal cord.

Computed tomography (CT) scan—An imaging technique in which cross-sectional x rays of the body are compiled to create a three-dimensional image of the body's internal structures.

Dementia—Progressive loss of mental abilities.

Magnetic resonance imaging (MRI)—An imaging technique that uses a large circular magnet and radio waves to generate signals from atoms in the body. These signals are used to construct images of internal structures.

the shunting procedure is performed. These techniques will also show any associated brain abnormalities. Cerebrospinal fluid should be examined if infection or tumor of the meninges is suspected. Patients with dementia or **mental retardation** should undergo neuropsychological testing to establish a baseline psychological profile before the shunting procedure.

Patients with normal pressure hydrocephalus may experience a temporary improvement in walking and mental abilities upon removal of a moderate amount of cerebrospinal fluid. This improvement may be an indication that shunting will improve their condition. However, patients who do not improve after temporary cerebrospinal fluid drainage may still benefit from ventricular shunt. When a case is in doubt, continuous monitoring of cerebrospinal fluid pressure (which in itself requires a surgical procedure) may indicate whether shunting is likely to be helpful.

Aftercare

To avoid infections at the shunt site, the area should be kept clean. Cerebrospinal fluid should be checked periodically by the doctor to be sure there is no infection or bleeding into the shunt. Cerebrospinal fluid pressure should be checked to be sure the shunt is operating properly. The eyes should be examined regularly because shunt failure may damage the nerve to the eyes (optic nerve). If not treated promptly, damage to the optic nerve causes irreversible loss of vision. Patients or caregivers should understand the life-threatening nature of shunt problems. All symptoms and signs of potential shunt failure or infection must be taken seriously.

Risks

Complications of shunting occur in 30% of cases, but only 5% are serious. Serious and long-term complications are bleeding under the outermost covering of the brain (**subdural hematoma**), infection, **stroke**, and shunt failure. Infection at the shunt site may cause a loss of intelligence. When shunts drain to the abdomen (ventriculoperitoneal shunts), fluid may accumulate in the abdomen or abdominal organs may be injured. If cerebrospinal fluid pressure is lowered too much, patients may have severe headaches, often with **nausea and vomiting**, whenever they sit up or stand.

Normal results

Of patients with normal pressure hydrocephalus who are treated with shunting, 25–80% experience long-term improvement. Normal pressure hydrocephalus is more likely to improve when it is caused by infection of or bleeding into the cerebrospinal fluid than when it occurs without an underlying cause. Walking difficulties and bladder control are more likely to improve than dementia is.

After shunting, the ventricles get smaller within three or four days. This shrinkage occurs even when hydrocephalus has been present for a year or more. Clinically detectable signs of improvement occur within a few weeks. The cause of hydrocephalus, duration of hydrocephalus before shunting, and associated brain abnormalities affect the outcome.

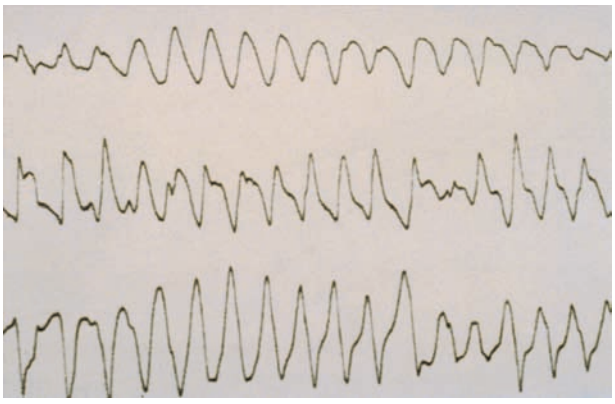
Laurie Barclay, MD

Ventricular tachycardia

Definition

Ventricular tachycardia (V-tach) is a rapid heart beat that originates in one of the lower chambers (the ventricles) of the heart. To be classified as tachycardia, the heart rate is usually at least 100 beats per minute.



An electrocardiographic image indicating a rapid heart beat. *(Custom Medical Stock Photo, Inc. Reproduced by permission.)*

KEY TERMS

Atrial—Having to do with the upper chambers of the heart.

Cardiomyopathy—A disease of the heart muscle.

Cardioversion—A electrical shock delivered to the heart to restore a normal rhythm.

Coronary artery—The artery that supplies blood to the heart muscle itself.

Electrocardiogram—A visual representation of the heart beat.

Fibrillation—Rapid, uncoordinated, quivering of the heart.

Palpitations—Uncomfortable feeling of the heart beat in the chest.

Valvular—Having to do with the valves inside the heart.

Description

A rapid heart rate can originate in either the left or right ventricle. Ventricular tachycardia which lasts more than 30 seconds is referred to as sustained ventricular tachycardia. A period of three to five rapid beats is called a salvo, and six beats or more lasting less than 30 seconds is called nonsustained ventricular tachycardia. Rapid ventricular rhythms are more serious than rapid atrial rhythms because they make the heart extremely inefficient. They also tend to cause more severe symptoms, and have a much greater tendency to result in **death**.

Although generally considered to be among the life-threatening abnormal rhythms, harmless forms of sustained V-tach do exist. These occur in people without any structural heart disease.

Causes and symptoms

Most ventricular tachycardias are associated with serious heart disease such as coronary artery blockage, **cardiomyopathy**, or **valvular heart disease**. V-tach is often triggered by an extra beat originating in either the right or left ventricle. It also occurs frequently in connection with a **heart attack**. V-tach commonly occurs within 24 hours of the start of the attack. It must be treated quickly to prevent fibrillation. After 48–72 hours of the heart attack, the risk of ventricular tachycardia is small. However, people who have suffered severe damage to the larger anterior wall of the heart have a second danger period, because V-tach often occurs during convalescence from this type of heart attack.

Sustained ventricular tachycardia prevents the ventricles from filling adequately so the heart can not pump normally. This results in loss of blood pressure, and can lead to a loss of consciousness and to **heart failure**.

The individual with V-tach almost always experiences palpitation, though some episodes cause no symptoms at all.

Diagnosis

Diagnosis is easily made with an electrocardiogram.

Treatment

Any episode of ventricular tachycardia that causes symptoms needs to be treated. An episode that lasts more than 30 seconds, even without symptoms, also needs to be treated. Drug therapy can be given intravenously to suppress episodes of V-tach. If blood pressure falls below normal, a person will need electric **cardioversion** ("shock") immediately.

Prognosis

With appropriate drug or surgical treatment, ventricular tachycardia can be controlled in most people.

Prevention

A person susceptible to sustained ventricular tachycardia often has a small abnormal area in the ventricles that is the source of the trigger event. This area can sometimes be surgically removed. If surgery is not an option, and drug therapy is not effective, a

device called an automatic cardioverter-defibrillator may be implanted.

Vesicoureteral reflux

Definition

Vesicoureteral reflux (VUR) refers to a condition in which urine flows from the bladder, back up the ureter, and into the kidneys.

Demographics

VUR is most often diagnosed in children. No large studies have been done to determine the incidence of VUR. Small studies suggest that the condition occurs in less than 1% of healthy children, although some experts believe this is an underestimate. The condition is 10 times more common in white children than in African-American children and is especially common (for unknown reasons) in children with red hair.

Description

The normal flow of urine begins in the collecting system of each kidney. Urine then flows out of each kidney and into a tube called the ureter. Each ureter leads into the bladder where the urine collects until it is passed out of the body. Normally, urine should flow only in this direction. In vesicoureteral reflux, however, urine that has already collected in the bladder is able to flow backwards from the bladder, up the ureter, and back into the collecting system of the kidney. VUR may be present in either one or both ureters.

Vesicoureteral reflux causes damage to the kidneys in two ways. The kidney is not designed to withstand very much pressure. When VUR is present, backpressure of the urine on the kidney is significant. This can damage the kidney. In addition, the kidney usually is sterile, meaning that no bacteria are normally present within it. In VUR, bacteria that enter through the urinary tract may be carried back up the ureter with the urine. These bacteria can enter the kidney, causing severe infection.

Causes and symptoms

Most cases of VUR are due to a defect in the way the ureter is implanted into the bladder. The angle may be wrong, or the valve that should allow urine only one-way entrance into the bladder may be weak. Structural defects of the urinary system also may cause VUR. These include a situation in which two ureters leave a kidney, instead of the usual one (duplicated ureters), and in which the ureter is greatly enlarged at the end leading into the bladder (ureterocele).

VUR alone does not usually cause symptoms. Symptoms develop when an infection has set in. The usual symptoms of infection include frequent need to urinate, **pain** or burning with urination, and blood or pus in the urine. Occasionally, VUR is suspected when a child has a difficult time becoming toilet trained. In these cases, the bladder may become irritable and spasm because it is never totally empty of urine. When the kidneys have been damaged, high blood pressure may develop.

Diagnosis

VUR is most often diagnosed in infancy or childhood because of frequent urinary tract infections (UTIs).

Tests

VUR is diagnosed by taking a series of x-ray pictures (called a voiding cystourethrogram). These are taken after putting a small tube (catheter) into the bladder. The bladder is then filled with a dye solution that lights up on the x-ray picture. Pictures are taken immediately, followed by x rays taken while the patient is urinating. This will allow reflux to be demonstrated, and will reveal whether the level of reflux increases when pressure increases during urination. Reflux is then graded based on the height and effects of the VUR:

- Grade I. VUR enters just the portion of the ureter closest to the bladder. The ureter appears normal in size.
- Grade II. VUR enters the entire ureter and goes up into the collecting system of the kidney. The ureter and the collecting system appear normal in size and structure.
- Grade III. VUR enters the entire ureter and kidney collecting system. Either the ureter or the collecting system are abnormal in size or shape.

KEY TERMS

Bladder—The muscular sac which receives urine from the kidneys, stores it, and ultimately works to remove it from the body during urination.

Electrolyte—Salts and minerals that ionize in body fluids. The major human electrolytes are sodium (Na+), potassium (K+), calcium (Ca 2+), magnesium (Mg2+), chloride (Cl-), phosphate (HPO4 2-), bicarbonate (HCO3-), and sulfate (SO4 2-). Electrolytes control the fluid balance of the body and are important in muscle contraction, energy generation, and almost all major biochemical reactions in the body.

Reflux—A condition in which flow is backwards from normal.

Ureter—A muscular tube leading from the kidney to the bladder, down which the urine flows.

- Grade IV. Similar to Grade III, but the ureter is greatly enlarged.
- Grade V. Similar to Grade IV, but the ureter is also abnormally twisted/curved, and the collecting system is greatly enlarged, with absence of the usual structural details.

Other tests that may be performed include a **urinalysis**, kidney and bladder ultrasound, intravenous pyelogram, or a nuclear scan of the kidney and bladder.

Treatment

Treatment depends on the grade of reflux that is diagnosed.

Drugs and monitoring

In grades I and II, the usual treatment involves long-term use of a small daily dose of **antibiotics** to prevent the development of infections. The urine is tested regularly to make sure that no infection occurs. The kidneys are evaluated regularly to make sure that they are growing normally and that no new scarring has occurred. Grade III VUR can be treated with antibiotics and careful monitoring. New infections, scarring, or stunting of kidney growth may result in a need for surgery. Grades IV and V are extremely likely to require surgery.

Surgery

Surgery for VUR consists of re-implanting the ureters into the bladder at a more normal angle. This usually improves the functioning of the valve leading into the bladder. When structural defects of the urinary system are present, surgery will almost always be required to repair these defects.

Prognosis

Prognosis is dependent on the grade of VUR. About 80% of children with grades I and II VUR simply grow out of the problem. As they grow, the ureter lengthens, changing its angle of entry into the bladder. About 50% of children with grade III VUR will require surgery. Nearly all children with grades IV and grade V VUR will require surgery. In these cases, it is usually best to perform surgery at a relatively young age in order to avoid damage and scarring to the kidneys.

Prevention

While there is no known method of preventing VUR, it is important to note that a high number of the siblings of children with VUR will also have VUR. Many of these siblings (about 36%) will have no symptoms, but will be discovered through routine examinations prompted by their brother's or sister's problems. It is important to identify these children, so that antibiotic treatment can be used to prevent the development of infection and kidney damage.

Vibriosis

Definition

Vibriosis is a disease caused by an infection with bacteria of the *Vibrio* genus, most commonly *Vibrio parahemolyticus* or *Vibrio vulnificus*. *Vibrio* bacteria cause **diarrhea**, skin infections, and/or blood infections. The diarrhea-causing *Vibrio parahemolyticus* is a relatively harmless infection, but *Vibrio vulnificus* infection, although rare, can lead to blood poisoning and **death** in many cases.

Description

Vibriosis is a general term referring to an infection by any member of the large group of *Vibrio* bacteria. The bacteria that causes **cholera** is in this group. Alternate names include non-cholera *Vibrio* infection, *Vibrio parahemolyticus* infection, and *Vibrio vulnificus* infection.

Vibrio parahemolyticus and *Vibrio vulnificus* are found in salt water. Infection with either of these two bacteria primarily occurs through eating contaminated raw seafood. Raw oysters are the usual source, although other seafood can carry the bacteria.

Vibrio parahemolyticus causes severe diarrhea. *Vibrio vulnificus* may cause diarrhea, but in persons with an underlying disease it may cause severe blood infections (septicemia or blood poisoning). Contact of a wound with seawater or contaminated seafood can lead to a *Vibrio vulnificus* skin infection.

Vibriosis is not very common in the United States. Most cases occur in coastal states between June and October. Between 1988 and 1991, there were only 21 reported cases of *Vibrio parahemolyticus* infection in the United States. Between 1988 and 1995, there were over 300 reports of *Vibrio vulnificus* infection in the United States.

Causes and symptoms

Vibriosis is caused by eating seafood contaminated with *Vibrio parahemolyticus* or *Vibrio vulnificus*. These bacteria damage the inner wall of the intestine, which causes diarrhea and related symptoms. *Vibrio vulnificus* can get through the intestinal wall and into the bloodstream.

Persons at risk for severe, often fatal vibriosis include those with **liver disease** (**cirrhosis**), excess iron (**hemochromatosis**), **thalassemia** (a blood disorder), **AIDS**, diabetes, or those who are immunosuppressed.

Symptoms of intestinal infection occur within two days of eating contaminated seafood. Symptoms last for 2 to 10 days and include watery diarrhea, abdominal cramps, **nausea**, **vomiting**, **headache**, and possibly **fever**. Symptoms of a blood infection develop one to two days after eating contaminated seafood, and include fever, chills, low blood pressure, and large fluid-filled blisters on the arms or legs. Similar blisters can also be produced by a *Vibrio vulnificus* skin infection.

Diagnosis

Vibriosis can be diagnosed and treated by an **infectious disease** specialist. It is diagnosed when *Vibrio* bacteria are grown from samples of stool, blood, or blister fluid. The symptoms and a recent history of eating raw seafood are very important clues for diagnosis.

Treatment

To counteract the fluid loss resulting from diarrhea, the patient will receive fluids either by mouth or intravenously. **Antibiotics** are not helpful in treating *Vibrio parahemolyticus* diarrhea.

However, *Vibrio vulnificus* infections are treated with antibiotics such as tetracycline (Sumycin, Achromycin V), or doxycycline (Monodox) plus ceftazidime (Ceftaz, Fortraz, Tazicef). One out of five patients with vibriosis requires hospitalization.

Prognosis

Most healthy persons completely recover from diarrhea caused by *Vibrio* bacteria. *Vibrio vulnificus* blood infection affects persons with underlying illness and is fatal in half of those cases. *Vibrio vulnificus* wound infections are fatal in one quarter of the cases.

Prevention

Contamination with *Vibrio* bacteria does not change the look, smell, or taste of the seafood. Vibriosis can be prevented by avoiding raw or undercooked shellfish, keeping raw shellfish and its juices away from cooked foods, and avoiding contact of wounded skin with seawater or raw seafood.

Vision training

Definition

Vision training, also known as vision therapy or orthoptics, consists of a variety of programs to enhance visual performance. It includes treatments for focusing, binocularity, and eye movement problems. Vision training is generally provided by an optometrist (O.D.).

Purpose

While visual acuity refers to how clearly each eye can see, vision training addresses how well the two eyes work together as a team. When looking at an object, the eyes must focus on the object (e.g., focusing for near or far objects). This involves the lens system of the eyes. The eyes must also work as a team and point at the same object so that the person does not see double. Aiming precisely at the same object will aid in depth perception (stereopsis) and seeing objects in three-dimensions (3D).

Although crossed eyes (**strabismus**) is an obvious condition, many defects in the coordination of eye movement are far less apparent. Even so, they can cause problems in reading, driving vehicles, and other complex tasks that require the integrated function of eyes and body. It is the goal of vision therapy to improve these subtle interactions using carefully devised exercises and devices.

The discipline, called "behavioral optometry," involves a careful evaluation of visual function, concentrating on complex skills such as rapid reading, distance perception, peripheral field awareness, accommodative facility, and the coordinated movement of each eye in relationship to the other. From that assessment the doctor goes on to design a course of exercises to correct the problems discovered. Like any other type of training, success requires practice and persistence until habits and reflexes can be retrained.

There are a number of different techniques and instruments used in vision therapy; the field is evolving rapidly in many directions. Some computerized exercises are being developed that promise better patient motivation. A device called the Dynavision apparatus has produced positive results in retraining **stroke** victims to operate motor vehicles. In addition, traditional forms of vision therapy have increased reading efficiency in an older age group (62–75 years).

Because the goal of vision training is to improve visual efficiency and visual processing, people having problems reading should consider a vision training evaluation. Children rubbing their eyes while reading, avoiding reading, or getting headaches while reading should be evaluated. Problems with sustaining focusing (accommodative insufficiency) or problems keeping words single (convergence or divergence problems) may be present. A full eye-health evaluation and vision training workup may reveal a problem. Vision training is also appropriate for people learning how to coordinate the eyes after surgery for strabismus. Vision training can also be used in lazy eye (**amblyopia**) and includes patching the eye and doing various exercises.

Dyslexia is a problem with following the flow of words when reading. Often the order of letters or words is reversed. It is a complex problem involving the way the brain processes the stream of information coming in from the eyes. While vision therapy is not a treatment for dyslexia or learning disabilities, there may be an underlying visual processing problem that may be present. Vision therapy can be part of a multidisciplinary approach to treating learning disabilities.

Sports vision deals with visual performance in sport-related activities. Protective eyewear is also a large consideration when participating in sports. Basketball, baseball, racquetball, and swimming (and other sports as well) can all cause injury to the eyes. Batting helmets with face shields, protective goggles with polycarbonate lenses, or something as simple as ultraviolet (UV) coatings on glasses to protect the eyes from the sun in outdoor sports such as golf can protect the eyes. Hitting a baseball or throwing a basketball into a hoop requires accurate fixation. Golfers need to see clearly and judge distance. Bifocals may need to be adjusted to allow for putting, driving, and reading the score card. While many of these issues (e.g., UV coatings) can be addressed at a regular eye exam, sports vision may be able to help with more specific, individual problems.

Precautions

Behavioral optometry is a relatively new field of study. Results are mixed. Newer techniques, more refined evaluation methods, and newer pieces of apparatus are continuously being appraised. More study results are needed to define the scope and benefits of this discipline.

Description

Vision therapy is individually tailored to the subject and the discovered problems. It can be a lengthy process with many variations that requires repetition

KEY TERMS

Accommodation—The focusing of the lens of the eye.

Binocular—Both eyes accurately pointing to the same object.

Stereopsis—The visual perception of depth, or the ability to see three-dimensionally. For this to occur, the person must be binocular.

until eye muscles, coordination, reflexes, habits, and the way the brain handles visual input are all retrained. Each program will be individualized. The patient should be aware of the time involved for treatment. Treatment can be from several weeks to several months depending upon the condition. Some insurance plans may cover vision training.

Preparation

If vision therapy is recommended, the optometrist will discuss thoroughly what is expected and necessary for success. The patient must be prepared to perform some eye exercises at home.

Aftercare

Even after the treatment is successful, it may be necessary to continue the exercises to maintain the benefits. It may be necessary to repeat treatment in the future.

Risks

No risk is involved. The treatment is safe.

Normal results

A carefully and individually tailored program of vision therapy should result in a gradual improvement in whatever complex visual function is being addressed. This progress ought to be measurable by using the same tests that were used to diagnose it. If the patient had symptoms, such as headaches or double vision while reading, it should be alleviated.

Abnormal results

Because the treatment is safe, the only abnormal result is failure. At the start of treatment, the optometrist should provide a reasonable estimate of what improvement to expect and how long it will take. Should this prove incorrect, either the treatment needs to be modified or the problem deemed untreatable by that method.

Visual impairment

Definition

Total blindness is the inability to tell light from dark, or the total inability to see. Visual impairment or low vision is a severe reduction in vision that cannot be corrected with standard glasses or **contact lenses** and reduces a person's ability to function at certain or all tasks. Legal blindness (which is actually a severe visual impairment) refers to a best-corrected central vision of 20/200 or worse in the better eye or a visual acuity of better than 20/200 but with a visual field no greater than 20° (e.g., side vision that is so reduced that it appears as if the person is looking through a tunnel).

Description

Vision is normally measured using a Snellen chart. A Snellen chart has letters of different sizes that are read, one eye at a time, from a distance of 20 ft. People with normal vision are able to read the 20 ft line at 20 ft–20/20 vision, or the 40 ft line at 40 ft, the 100 ft line at 100 ft, and so forth. If at 20 ft the smallest readable letter is larger, vision is designated as the distance from the chart over the size of the smallest letter that can be read.

Eye care professionals measure vision in many ways. Clarity (sharpness) of vision indicates how well a person's central visual status is. The diopter is the unit of measure for refractive errors such as nearsightedness, farsightedness, and **astigmatism** and indicates the strength of corrective lenses needed. People do not just see straight ahead; the entire area of vision is called the visual field. Some people have good vision (e.g., see clearly) but have areas of reduced or no vision (blind

spots) in parts of their visual field. Others have good vision in the center but poor vision around the edges (peripheral visual field). People with very poor vision may be able only to count fingers at a given distance from their eyes. This distance becomes the measure of their ability to see.

The World Health Organization (WHO) defines impaired vision in five categories:

- Low vision 1 is a best corrected visual acuity of 20/70.
- Low vision 2 starts at 20/200.
- Blindness 3 is below 20/400.
- Blindness 4 is worse than 5/300
- Blindness 5 is no light perception at all.
- A visual field between 5° and 10° (compared with a normal visual field of about 120°) goes into category 3; less than 5° into category 4, even if the tiny spot of central vision is perfect.

Color blindness is the reduced ability to perceive certain colors, usually red and green. It is a hereditary defect and affects very few tasks. Contrast sensitivity describes the ability to distinguish one object from another. A person with reduced contrast sensitivity may have problems seeing things in the fog because of the decrease in contrast between the object and the fog.

According to the WHO there are over 40 million people worldwide whose vision is category 3 or worse, 80% of whom live in developing countries. Half of the blind population in the United States is over 65 years of age.

Causes and symptoms

The leading causes of blindness include:

- macular degeneration
- glaucoma
- cataracts
- diabetes mellitus

Other possible causes include infections, injury, or **nutrition**.

Infections

Most infectious eye diseases have been eliminated in the industrialized nations by sanitation, medication, and public health measures. Viral infections are the main exception to this statement. Some infections that may lead to visual impairment include:

- Herpes simplex keratitis. A viral infection of the cornea. Repeated occurrences may lead to corneal scarring.
- Trachoma. This disease is responsible for six to nine million cases of blindness around the world, of the third of a billion who have the disease. Trachoma is caused by an incomplete bacterium, *Chlamydia trachomatis*, that is easily treated with standard antibiotics. It is transmitted directly from eye to eye, mostly by flies. The chlamydia gradually destroy the cornea.
- Leprosy (Hansen's disease). This is another bacterial disease that has a high affinity for the eyes. It, too, can be effectively treated with medicines.
- River blindness. Much of the tropics of the Eastern Hemisphere are infested with *Onchocerca volvulus*, a worm that causes "river blindness." This worm is transmitted by fly bites and can be treated with a drug called ivermectin. Nevertheless, 28 million people have the disease, and 40% of them are blind from it.

Other causes

Exposure of a pregnant woman to certain diseases (e.g., **rubella** or **toxoplasmosis**) can cause congenital eye problems. Injuries to the eyes can result in blindness. Very little blindness is due to disease in the brain or the optic nerves. **Multiple sclerosis** and similar nervous system diseases, brain tumors, diseases of the eye sockets, and head injuries are rare causes of blindness.

Nutrition

Vitamin A deficiency is a widespread cause of corneal degeneration in children in developing nations. As many as five million children develop xerophthalmia from this deficiency each year. Five percent end up blind.

Diagnosis

A low vision exam is slightly different from a general exam. While a case history, visual status, and eye health evaluation are common to both exams, some things do differ. Eye charts other than a Snellen eye chart will be used. Testing distance will vary. A trial frame worn by the patient is usually used instead of the instrument containing the lenses the patient sits behind (phoropter). Because the low vision exam is slightly more goal oriented than a general exam, for example, what specifically is the patient having trouble with (reading, seeing street signs, etc.) different optical and nonoptical aids will generally be tried. Eye health is the last thing to be checked so that the lights necessary to examine the eyes will not interfere with the rest of the testing.

Treatment

There are many options for patients with visual impairment. There are optical and nonoptical aids. Optical aids include:

- Telescopes. May be used to read street signs.
- Hand magnifiers. May be used to read labels on things at the store.
- Stand magnifiers. May be used to read.
- Prisms. May be used to move the image onto a healthy part of the retina in some eye diseases.
- Closed circuit television (CCTV). For large magnification (e.g., for reading).

Nonoptical aids can include large print books and magazines, check-writing guides, large print dials on the telephone, and more.

For those who are blind, there are enormous resources available to improve the quality of life. For the legally blind, financial assistance for help may be possible. Braille and audio books are increasingly available. Guide dogs provide well-trained eyes and independence. Orientation and mobility training is available. There are special schools for blind children and access to disability support through Social Security and private institutions.

Prognosis

The prognosis generally relates to the severity of the impairment and the ability of the aids to correct it. A good low vision exam is important to be aware of the latest low vision aids.

Prevention

Regular eye exams are important to detect silent eye problems (e.g., glaucoma). Left untreated, glaucoma can result in blindness.

Corneal infections can be treated with effective **antibiotics**. When a cornea has become opaque beyond recovery it must be transplanted. Good hygiene (e.g., washing hands frequently) to prevent infection, proper use of contact lenses, and not sharing makeup are just some ways to guard against corneal infections.

Cataracts should be removed when they interfere with a person's quality of life.

Primary prevention addresses the causes before they ever begin. Fly control can be accomplished by simple sanitation methods. Public health measures can reduce the incidence of many infectious diseases. Vitamin A supplementation (when appropriate) will eliminate xerophthalmia completely. It is possible that protecting the eyes against ultraviolet (UV) light will reduce the incidence of cataracts, **macular degeneration**, and some other eye diseases. UV coatings can be placed on regular glasses, sunglasses, and ski goggles. Patients should ask their eye care professional about UV coatings. Protective goggles should also be worn in certain situations (e.g., certain jobs, sports, even mowing the lawn).

Secondary prevention addresses treating established diseases before they cause irreversible eye damage. Having general physical checkups can also detect systemic diseases such as diabetes or high blood pressure. Control of diabetes is very important in preserving sight.

KEY TERMS

Cornea—The clear dome-shaped structure that is part of the front of the eye. It lies in front of the colored part of the eye (iris).

Diabetic retinopathy—Retinal disease caused by the damage diabetes does to small blood vessels.

Phoropter—The instrument used to measure refractive status of the eyes. It contains many lenses which are then changed in front of the eyes while the patient is looking at an eye chart. This is when the doctor usually asks, "Which is better, one or two?"

Xerophthalmia—A drying of the cornea and conjunctiva.

Visualization *see* **Guided imagery**

Vitamin A deficiency

Definition

Vitamin A deficiency exists when the chronic failure to eat sufficient amounts of vitamin A or beta-carotene results in levels of blood-serum vitamin A that are below a defined range. Beta-carotene is a form of pre-vitamin A, which is readily converted to vitamin A in the body. Night blindness is the first symptom of vitamin A deficiency. Prolonged and severe vitamin A deficiency can produce total and irreversible blindness.

Description

Vitamin A (called retinol in mammals) is a fat-soluble vitamin. The recommended dietary allowance (RDA) for vitamin A is 1.0 mg/day for an adult man and 0.8 mg/day for an adult woman. Since beta-carotene is converted to vitamin A in the body, the body's requirement for vitamin A can be supplied entirely by beta-carotene. Six mg of beta-carotene are considered to be the equivalent of 1 mg of vitamin A. The best sources of vitamin A are eggs, milk, butter, liver, and fish, such as herring, sardines, and tuna. Beef is a poor source of vitamin A. Plants do not contain vitamin A, but they do contain beta-carotene and other carotenoids. The best sources of beta-carotene are dark-green, orange, and yellow vegetables; spinach, carrots, oranges, and sweet potatoes are excellent examples. Cereals are poor sources of beta-carotene.

Vitamin A is used for two functions in the body. Used in the eye, it is a component of the eye's light-sensitive parts, containing rods and cones, that allow night-vision or seeing in dim-light circumstances. Vitamin A (retinol) occurs in the rods. Another form of Vitamin A, retinoic acid, is used in the body for regulating the development of various tissues, such as the cells of the skin, and the lining of the lungs and intestines. Vitamin A is important during embryological development, since without vitamin A, the fertilized egg cannot develop into a fetus.

Causes and symptoms

Vitamin A deficiency occurs with the chronic consumption of **diets** that are deficient in both vitamin A and beta-carotene. When vitamin A deficiency exists in the developed world, it tends to happen in alcoholics or in people with diseases that affect the intestine's ability to absorb fat. Examples of such diseases are **celiac disease** (chronic nutritional disorder), **cystic fibrosis**, and **cholestasis** (bile-flow failure or interference). Vitamin A deficiency occurred in infants during the early 1900s in Denmark. The deficiency resulted when milk fat was made into butter for export, leaving the by-product (skimmed milk) for infant feeding. Vitamin A deficiency has taken place in infants in impoverished populations in India, where the only foods fed to the infants were low in beta-carotene. Vitamin A deficiency is also common in areas like Southeast Asia, where polished rice, which lacks the vitamin, is a major part of the diet.

The earliest symptom of vitamin A deficiency is night blindness. Prolonged deficiency results in drying of the conjunctiva (the mucous membrane that lines the inner surface of the eyelids and extends over the forepart of the eyeball). With continued vitamin A deficiency, the drying extends to the cornea (xerophthalamia). The cornea eventually shrivels up and becomes ulcerated (keratinomalacia). Superficial, foamy gray triangular spots may appear in the white of the eye (Bitot's spots). Finally, inflammation and infection occur in the interior of the eye, resulting in total and irreversible blindness.

Diagnosis

Vitamin A status is measured by tests for retinol. Blood-serum retinol concentrations of 30–60 mg/dL are considered in the normal range. Levels that fall below this range indicate vitamin A deficiency. Night blindness is measured by a technique called electroretinography. Xerophthalamia, keratinomalacia, and Bitot's spots are diagnosed visually by trained medical personnel.

Treatment

Vitamin A deficiency can be prevented or treated by taking vitamin supplements or by getting injections of the vitamin. The specific doses given are oral retinyl palmitate (110 mg), retinyl acetate (66 mg), or injected retinyl palmitate (55 mg) administered on each of two

KEY TERMS

Bitot's spots—Bitot's spots are superficial, foamy gray, triangular spots on the white of the eyeball.

Carotenoids—Carotenoids are yellow to deep-red pigments.

Conjunctiva—The conjunctiva is a clear layer of cells that covers the eye and directly contacts the atmosphere. The conjunctiva is about 5 cells thick.

Cornea—The cornea is a clear layer of cells that covers the eye, just under the conjunctiva. The cornea is about 50 cells thick.

Fat-soluble vitamin—Fat-soluble vitamins can be dissolved in oil or in melted fat. Water-soluble vitamins can be dissolved in water or juice.

Keratomalacia—Keratomalacia is ulceration of the cornea.

Recommended Dietary Allowance (RDA)—The Recommended Dietary Allowances are quantities of nutrients in the diet that are required to maintain good health in people. RDAs are established by the Food and Nutrition Board of the National Academy of Sciences, and may be revised every few years. A separate RDA value exists for each nutrient. The RDA values refer to the amount of nutrient expected to maintain good health in people. The actual amounts of each nutrient required to maintain good health in specific individuals differ from person to person.

Xerophthalmia—Xerophthalmia is a dry, thickened, lusterless condition of the eyeball resulting from vitamin A deficiency.

successive days, and once a few weeks later if symptoms are not relieved.

Prognosis

The prognosis for correcting night blindness is excellent. Xerophthalamia can be corrected with vitamin A therapy. Ulcerations, tissue **death**, and total blindness, caused by severe vitamin A deficiency, cannot be treated with vitamin A.

Prevention

Vitamin A deficiency can be prevented by including foods rich in vitamin A or beta-carotene as a regular component of the diet; liver, meat, eggs, milk, and dairy products are examples. Foods rich in beta-carotene include red peppers, carrots, pumpkins, as well as those just mentioned. Margarine is rich in beta-carotene, because this chemical is used as a coloring agent in margarine production. In Africa, Indonesia, and the Philippines, vitamin A deficiency is prevented by public health programs that supply children with injections of the vitamin.

Vitamin B_2 deficiency *see* **Riboflavin deficiency**

Vitamin B_6 deficiency

Definition

Vitamin B_6 is used by the body as a catalyst in reactions that involve amino acids. Vitamin B_6 deficiency is rare, since most foods eaten contain the vitamin.

Description

Vitamin B_6 is a water-soluble vitamin. The recommended dietary allowance (RDA) for vitamin B_6 is 2.0 mg/day for the adult man and 1.6 mg/day for the adult woman. Vitamin B_6 in the diet generally occurs as a form called pyridoxal phosphate. In this form, it cannot be absorbed by the body. During the process of digestion, the phosphate group is removed, and pyridoxal is produced. However, the body readily absorbs pyridoxal, and converts it back to the active form of the vitamin (pyridoxal phosphate).

Poultry, fish, liver, and eggs are good sources of vitamin B_6, consisting of about 3–4 mg vitamin/kg food; meat and milk contain lesser amounts of the vitamin. The vitamin also occurs, at about half this level, in a variety of plant foods, including beans, broccoli, cabbage, and peas. Vitamin B_6 tends to be destroyed with prolonged cooking, with storage, or with exposure to light.

KEY TERMS

Amino acid—Amino acids are small molecules that are used as building blocks for all proteins. Some amino acids are also used in the body for the manufacture of hormones. There are about 20 nutritionally important amino acids, including glutamic acid, glycine, methionine, lysine, tryptophan, serine, and glycine.

Fat-soluble vitamins—Fat-soluble vitamins can be dissolved in oil or in melted fat.

Recommended Dietary Allowance (RDA)—The Recommended Dietary Allowances (RDAs) are quantities of nutrients in the diet that are required to maintain good health in people. RDAs are established by the Food and Nutrition Board of the National Academy of Sciences, and may be revised every few years. A separate RDA value exists for each nutrient. The RDA values refer to the amount of nutrient expected to maintain good health in people. The actual amounts of each nutrient required to maintain good health in specific individuals differ from person to person.

Water-soluble vitamins—Water-soluble vitamins can be dissolved in water or juice.

As mentioned, vitamin B_6 takes various forms. One of these forms, called pyridoxine, is relatively stable. For this reason, pyridoxine is the form of vitamin B_6 that is used in vitamin supplements, or when foods are fortified. Apples and other fruits are poor sources of the vitamin, containing only 0.2–0.6 mg vitamin/kg food.

Vitamin B_6, used mainly in the body for the processing of amino acids, performs this task along with certain enzymes. The enzyme that participates in this type of complex is aminotransferase. Several types of aminotransferase exist. With vitamin B_6 deficiency, while aminotransferase continues to occur in the various organs of the body, there is an abnormally low level of the active vitamin B_6/aminotransferase complex present. Thus, this vitamin deficiency results in the impairment of a variety of activities in the body. With supplement correction of the vitamin B_6 deficiency, the aminotransferase then readily forms the active complex, and normal metabolism is restored.

Vitamin B_6 converts certain amino acids (glutamic acid, aspartic acid, glycine) to energy. This allows the body to process all dietary protein, even when the dietary protein is in excess of the body's needs. Vitamin B_6 also allows the body to synthesize certain amino acids. For example, if the diet is deficient or low in certain amino acids, such as glycine or serine, vitamin B_6 enables the body to make them from sugar. Vitamin B_6 is used also for the synthesis of certain hormones, such as adrenaline.

Causes and symptoms

Vitamin B_6 deficiency occurs rarely. When it does, it is usually associated with poor absorption of nutrients in the gastrointestinal tract (as in **alcoholism**, or with chronic **diarrhea**), the taking of certain drugs (as isoniazid, hydrolazine, penicillamine) that inactivate the vitamin, with genetic disorders that inhibit metabolism of the vitamin, or in cases of **starvation**.

The symptoms of vitamin B_6 deficiency in adults are only vaguely defined. These include nervousness, irritability, **insomnia**, muscle weakness, and difficulty in walking. Vitamin B_6 deficiency may produce fissures and cracking at the corners of the mouth. The deficiency occurred in infants fed early versions of commercial canned infant formula, when the vitamin had been inadvertently omitted from the formula. This error resulted in infants failing to grow, in irritability, and in seizures.

Diagnosis

Vitamin B_6 status is measured by the transaminase stimulation test. This test requires extraction of red blood cells, and placement of the cells in two test tubes. Special chemicals (reagents) are added to both test tubes to allow for measurement of aminotransferase. This enzyme requires pyridoxal phosphate. A known quantity of pure pyridoxal phosphate is added to one of the test tubes. The activity level of the enzyme is measured, and compared, in both test tubes. If the added pyridoxal phosphate did not stimulate activity, the patient is considered not to be deficient in vitamin B_6. Neither is the patient considered deficient if only slight stimulation occurred. But if a stimulation of four-fold or more occurred, a vitamin B_6 deficiency is present.

Treatment

Vitamin B_6 deficiency can be prevented or treated with consumption of the recommended dietary allowance, as supplied by food or by vitamin supplements.

Prognosis

The prognosis for correcting vitamin B_6 deficiency is excellent.

Prevention

Vitamin B_6 deficiency is not a major concern for most people. The deficiency can be prevented with consumption of a mixed diet that includes poultry, fish, eggs, meat, vegetables, and grains.

Vitamin D deficiency

Definition

Vitamin D deficiency exists when the concentration of 25-hydroxy-vitamin D (25-OH-D) in the blood serum occurs at 12 ng/mL (nanograms/milliliter), or less. The normal concentration 25-hydroxy-vitamin D in the blood serum is 25–50 ng/mL. When vitamin D deficiency continues for many months in growing children, the disease commonly referred to as **rickets** will occur. A prolonged deficiency of the vitamin in adults results in osteomalacia. Both diseases involve defects in bones.

Demographics

One group of researchers at Oxford University estimated in 2010 that over three billion people in the world have vitamin D levels lower than are necessary to influence optimum health, and that one billion people have a deficiency of vitamin D. The Oxford group also linked vitamin D deficiency to increased susceptibility to some autoimmune diseases including **multiple sclerosis** (MS), Type-1 diabetes, and **rheumatoid arthritis**, as well as certain cancers. Severe vitamin D deficiency is less common in the United States and other industrialized countries because of the wide availability of vitamin D-fortified infant formulas and milks. However, in northern latitudes where there is less sunshine, vitamin D deficiencies are more common. Vitamin D deficiency is also slightly more common in inner city areas, because environmental factors such as smog can block the necessary ultraviolet (UV) component of sunlight. Children with darkly pigmented skin are more likely to be vitamin D deficient than light skinned children. Children who are exclusively breast-fed without vitamin D supplementation, particularly if they are not exposed to sunlight, are at higher risk of vitamin D deficiency.

Description

Vitamin D is a fat-soluble vitamin, meaning it dissolves in fat. While some vitamin D is supplied by the diet, most of it is made in the body. To make vitamin D, cholesterol, a sterol that is widely distributed in animal tissues and occurs in the yolk of eggs, as well as in various oils and fats, is necessary. Once cholesterol is available in the body, a slight alteration in the cholesterol molecule occurs, with one change that takes place in the skin. This alteration requires the energy of sunlight (or ultraviolet light). Vitamin D deficiency, as well as rickets and osteomalacia, tends to occur in persons who do not get enough sunlight and who fail to eat foods that are rich in vitamin D.

Once consumed, or made in the body, vitamin D is further altered to produce a hormone called 1,25-dihydroxy-vitamin D (1,25-diOH-D). The conversion of vitamin D to 1,25-diOH-D does not occur in the

skin, but in the liver and kidney. First, vitamin D is converted to 25-OH-D in the liver; it then enters the bloodstream, where it is taken–up by the kidneys. At this point, it is converted to 1,25-diOH-D. Therefore, the manufacture of 1,25-diOH-D requires the participation of various organs of the body—the liver, kidney, and skin.

The purpose of 1,25-diOH-D in the body is to keep the concentration of **calcium** at a constant level in the bloodstream. The maintenance of calcium at a constant level is absolutely required for human life to exist, since dissolved calcium is required for nerves and muscles to work. One of the ways in which 1,25-diOH-D accomplishes this mission is by stimulating the absorption of dietary calcium by the intestines.

The sequence of events that can lead to vitamin D deficiency, then to bone disease, is as follows: a lack of vitamin D in the body creates an inability to manufacture 1,25-diOH-D, which results in decreased absorption of dietary calcium and increased loss of calcium in the feces. When this happens, the bones are affected. Vitamin D deficiency results in a lack of bone mineralization (calcification) in growing persons, or in an increased demineralization (decalcification) of bone in adults.

Causes and symptoms

Vitamin D deficiency can be caused by conditions that result in little exposure to sunlight. These conditions include: living in northern countries; having dark skin; being elderly or an infant, and having little chance to go outside; and covering one's face and body, such as for religious reasons. Many Arab women cover the entire body with black cloth, and wear a veil and black gloves when they go outside. These women may acquire vitamin D deficiency, even though they live in a sunny climate.

Most foods contain little or no vitamin D. As a result, sunshine is often a deciding factor in whether vitamin D deficiency occurs. Although fortified milk and fortified infant formula contain high levels of vitamin D, human breast milk is rather low in the vitamin. The term fortified means that **vitamins** are added to the food by the manufacturer.

To say that a food is high or low in vitamin D means how much of that food needs to be eaten in order to prevent vitamin deficiency and maintain good health. An exact meaning can be provided by comparing the Recommended Dietary Allowance of vitamin D with the amount of vitamin D supplied by a particular food per day. The Recommended Dietary Allowance, also referred to as RDA, is a recommendation based on data derived from different population groups and ages. The RDA for vitamin D for adults is 200 International Units (IU) per day, and can be supplied by eating approximately about three pounds (1.5 kg) of beef, five pounds (2.0 kg) of corn oil, or 200 pounds (100 kg) of cabbage. Few people, however, would want to eat three pounds of beef in one day, and no human being is capable of eating 200 pounds of cabbage in a day; therefore, these foods are poor sources of vitamin D. However, saltwater fish such as salmon, herring, and sardines are rich in vitamin D, supplied from the oils produced by these fish. The RDA can also be supplied by eating roughly two ounces (50 g) of salmon or less than a tenth of an ounce (2 g) of cod liver oil. Since fortified milk contains 400 IU per quart, half a quart of milk provides the RDA. For comparison, human breast milk contains only 4–60 IU per quart.

No harm is likely to result from vitamin D deficiency that occurs for only a few days a year. If the deficiency occurs for a period of many months or years, however, rickets or osteomalacia may develop. The symptoms of rickets include bowed legs and bowed arms. The bowed appearance is due to the softening of bones, and their bending if the bones are weight bearing. Bone growth occurs through the creation of new cartilage, a soft substance at the ends of bones. When the mineral calcium phosphate is deposited onto the cartilage, a hard structure is created. In vitamin D deficiency, though, calcium is not available to create hardened bone, and the result is soft bone. Other symptoms of rickets include particular bony bumps on the ribs called rachitic rosary (beadlike prominences at the junction of the ribs with their cartilages) and knock-knees. Seizures may also occasionally occur in a child with rickets, because of reduced levels of dissolved calcium in the bloodstream.

Although osteomalacia is rare in the United States, symptoms of this disease include reduced bone strength, an increase in bone **fractures**, and sometimes bone **pain**, muscle weakness, and a waddling walk.

Diagnosis

Vitamin D deficiency is diagnosed by measuring the level of 25-hydroxy-vitamin in blood serum. The normal level or concentration of this form of the vitamin ranges from 25–50 ng/mL. Deficiency occurs when this level decreases to about 12 ng/mL or less. As mentioned previously, 25-OH-D is not the active form of the vitamin. It must be converted to 1,25-diOH-D in order to cause responses in various organs of the body. However, the levels of vitamin D, or of 1,25-dihydroxy-vitamin D in the blood, do not give a reliable picture of whether a person is deficient in the

KEY TERMS

25-hydroxy-vitamin—The form of vitamin D that is measured in order to assess vitamin D deficiency.

Cholesterol—A fat-soluble steroid alcohol (sterol) found in animal fats and oils, and in egg yolks. The human body needs cholesterol to produce vitamin D.

Fat–soluble vitamin—A vitamin that dissolves easily in fat or oil, but not in water. The fat–soluble vitamins are vitamins D, E, A, and K.

International unit (IU)—A measurement of biological activity in which one IU is equal to one mg (milligram).

Osteomalacia—Osteomalacia is a bone disease that occurs in adults and is caused by a prolonged period of vitamin D deficiency.

Rachitic rosary—Beadlike bumps present at the junction of the ribs with their cartilages; often seen in children with rickets.

Recommended Dietary Allowance (RDA)—The amount of nutrients, including vitamins, that should be supplied by foods on a daily basis to maintain normal health. Recommendations are based on data obtained from different population groups and ages.

Rickets—A bone disease that occurs in infants and growing children and is caused by a prolonged period of vitamin D deficiency.

vitamin. For this reason, they are not measured when testing for vitamin D deficiency.

Rickets is diagnosed by x–ray examination of leg bones. A distinct pattern of irregularities, abnormalities, and a coarse appearance can be clearly seen with rickets. Osteomalacia is also diagnosed with x–ray examination. Measurements of blood plasma 25-OH-D, blood plasma calcium, and blood plasma parathyroid hormone must also be obtained for the diagnosis of these diseases. Parathyroid hormone and 1,25-diOH-D work together in the body to regulate the levels of calcium in the blood.

Treatment

Rickets heals promptly with 4,000 IU of oral vitamin D per day administered for approximately one month. During this treatment, the doctor should monitor the levels of 25-OH-D in plasma to make certain they are raised to a normal value. Bone abnormalities (visible by x ray) generally disappear gradually over a period of three to nine months. Parents are instructed to take their infants outdoors for approximately 20 minutes per day with their faces exposed. Children should also be encouraged to play outside. Foods that are good sources of vitamin D include cod liver oil, egg yolks, butter, and oily fish. Some foods, including milk and breakfast cereals, are also fortified with synthetic vitamin D.

Osteomalacia is treated by injesting 2,500 IU per day of vitamin D for about three months. Measurements of 25-OH-D, calcium, and parathyroid hormone should be obtained after the treatment period to make sure the therapy did, in fact, result in normal blood values. In post-menopausal women with bone loss, or persons with parathyroid disease, vitamin D deficiency is often treated with therapeutic supplements of 50,000 IU taken once or more per week for a select short period of time, usually about eight weeks.

Care must be taken in treating vitamin D deficiency, since high doses of vitamin D are toxic and can result in the permanent deposit of **minerals** in the heart, lungs, and kidneys. Symptoms of toxicity are **nausea**, **vomiting**, pain in joints, and decreased appetite. In adults, vitamin D toxicity can occur with ingesting 50,000 IU or more per day. In infants, toxicity occurs with 1,000 IU per day. The continued intake of toxic doses results in **death**.

Rickets and osteomalacia are almost always treated with oral supplements of vitamin D, with the recommendation to acquire daily exposure to direct sunlight. An alternative to sunlight is the use of an ultraviolet (UV) lamp. When using UV lamps, the eyes must be covered to protect them against damage. Many types of sunglasses allow UV light to pass through, so only those that are opaque to UV light should be used. Attempts to acquire sunlight through glass windows fail to help the body make vitamin D. The reasons is that UV light does not pass through window glass.

Rickets may also occur with calcium deficiency, even when a child is regularly exposed to sunshine. This type of rickets has been found in various parts of Africa. The bone deformities are similar to, or are the same as, those that occur in typical rickets; however,

calcium deficiency rickets is treated by increasing the amount of calcium in the diet. No amount of vitamin D can cure the rickets of a child with a diet that is extremely low in calcium. For this reason, specialists recommend that calcium be given in conjunction with vitamin D supplementation.

Prognosis

The prognoses for correcting vitamin D deficiency, rickets, and osteomalacia are excellent. Vitamin D treatment results in the return of bone mineralization to a normal rate, the correction of low plasma calcium levels, the prevention of seizures, and a recovery from bone pain. On the other hand, deformities such as bowed legs and the rachitic rosary persist throughout adult life.

Prevention

Food fortification has almost completely eliminated rickets in the United States. Vitamin D deficiency can be prevented by acquiring the RDA through drinking fortified milk and eating fortified cereals. For those who cannot drink milk, supplements of pills might be considered. In some older people, a 400 IU supplement may not be enough to result in the normal absorption of calcium; therefore, daily doses of 10,000 IU per day may be needed. For infants who are fed only breast milk (and rarely exposed to sunshine), a daily supplement of 200–300 IU is often recommended.

Rickets continues to be a problem in Africans and Asian Indians who migrate to Canada or Great Britain, especially where these immigrants do not drink fortified milk. Prevention of rickets in these populations is attempted through educational programs sponsored by the government.

Vitamin E deficiency

Definition

Vitamin E deficiency is a very rare problem that results in damage to nerves. When vitamin E deficiency does occur, it strikes people with diseases that prevent the absorption of dietary fats and fat-soluble nutrients. Since vitamin E is a fat-soluble vitamin, it has some of the properties of fat.

Description

The recommended dietary allowance (RDA) for vitamin E is 10 mg/day for an adult man, 10 mg/day for an adult woman, and 3 mg/day for an infant. Vitamin E occurs in foods in a variety of related forms. The most potent and useful form of vitamin E is called alpha-tocopherol. The best sources of vitamin E are vegetable oils, such as corn oil, soy oil, and peanut oil. Animal fats, such as butter and lard, contain lower levels of the vitamin. Corn oil contains about 16 mg of alpha-tocopherol per 100 g oil. Wheat-germ oil contains 120 mg alpha-tocopherol per 100 g oil. Fish, eggs, and beef contain relatively low levels of the vitamin, with about 1 mg per 100 g food.

Vitamin E seems to have only one function in the body: the prevention of the natural and continual process of deterioration of all body tissues. This deterioration is provoked by a number of causes; one of these is toxic oxygen. During the body's metabolism of atmospheric oxygen, toxic oxygen is produced continuously in the body by the formation of by-products. These toxic by-products include hydrogen peroxide, superoxide, and hypochlorite.

Hypochlorite is a natural product, produced by cells of the immune system. It is also the active component of bleach. Once formed, toxic oxygen can damage

KEY TERMS

Fat-soluble vitamin—Fat-soluble vitamins can be dissolved in oil or in melted fat.

Recommended dietary allowance (RDA)—The quantity of a given nutrient in the diet that is required to maintain good health in people. RDAs are established by the Food and Nutrition Board of the National Academy of Sciences and may be revised every few years. A separate RDA value exists for each nutrient. The RDA values refer to the amount of nutrient expected to maintain good health in people. The actual amounts of each nutrient required to maintain good health in specific individuals differ from person to person.

Toxic oxygen—Oxygen is required for life, as it is needed for energy production. When oxygen is used by the body, most of it is converted to water. However, a small fraction of the oxygen breathed is converted to toxic oxygen. The body uses several different processes for preventing and repairing toxic-oxygen damage. One of these processes involves vitamin E.

Water-soluble vitamins—Water-soluble vitamins can be dissolved in water or juice.

various parts of the body, such as the membranes which form the boundaries of every cell. Vitamin E serves the body in protecting membranes from toxic oxygen damage. In contrast, vitamin C serves to protect the aqueous, or watery, regions of the cell from toxic oxygen damage. The membranes that are most sensitive to toxic oxygen damage are the membranes of nerves; therefore, the main symptom of vitamin E deficiency is damage to the nervous system.

Causes and symptoms

As mentioned, when vitamin E deficiency occurs, it strikes people with diseases that prevent the absorption of dietary fats and fat-soluble nutrients. These diseases include **cystic fibrosis**, **pancreatitis**, and **cholestasis** (bile-flow obstruction). Bile salts, produced in the liver, are required for the absorption of fats. Cholestasis causes a decrease in the formation of bile salts and the consequent failure of the body to absorb dietary fats. For this reason, this disease may result in vitamin E deficiency. Premature infants may be at risk for vitamin E deficiency because they may be born with low tissue levels of the vitamin, and because they have a poorly developed capacity for absorbing dietary fats. Infants suffering from fat-malabsorption diseases can develop symptoms of vitamin E deficiency by age two. In adults, the onset of a fat-malabsorption disease can provoke vitamin E deficiency after a longer period, as an example, 10 years.

Patients with colorectal **cancer** caused by the so-called Ki-ras mutation have also been shown to absorb less vitamin E from their diet than either normal control subjects or cancer patients without the mutation. The relationship between genetic mutations and dietary factors requires more intensive study.

Vitamin E deficiency in humans results in ataxia (poor muscle coordination with shaky movements), decreased sensation to vibration, lack of reflexes, and **paralysis** of eye muscles. One particularly severe symptom of vitamin E deficiency is the inability to walk.

Another symptom of early vitamin E deficiency in children with cystic fibrosis is a decline in cognitive function, which results in difficulty with reading and falling behind in other intellectual skills during the elementary school years. Researchers have urged the introduction of neonatal screening in order to offset the potential effects of early vitamin E deficiency.

More recently, the suggestion has been made that vitamin E deficiency may be involved in the development of partial open-angle glaucoma (POAG), an eye disorder whose causes are not fully understood as of the early 2000s. The possibility that POAG is a vitamin-deficiency disorder, however, needs further research.

Diagnosis

Vitamin E status is measured by assessment of the content of alpha-tocopherol in the blood plasma, using a method called high-pressure liquid chromatography. Blood plasma levels of alpha-tocopherol that are 5.0 mg/l, or above, indicate normal vitamin E status; levels below 5.0 mg/l indicate vitamin E deficiency.

Treatment

Vitamin E deficiency that occurs with cholestatic **liver disease** or other malabsorption syndromes can be treated with weekly injections of 100 mg alpha-tocopherol that may continue for six months. Vitamin E deficiency in premature infants may require treatment for only a few weeks.

Prognosis

The prognosis for correcting the neurological symptoms of vitamin E deficiency is fair to excellent.

Prevention

The prevention of vitamin E deficiency should not be a concern for most people, since the vitamin is found in a wide variety of foods. Attention has been given to the theory that vitamin E serves to protect against cancer and **atherosclerosis**. The evidence that normal levels of vitamin E protect against atherosclerosis is fairly convincing. However, there is little or no proof that vitamin E intake, above and beyond the recommended daily allowance (RDA), can prevent cancer or atherosclerosis.

Vitamin K deficiency

Definition

Vitamin K deficiency exists when chronic failure to eat sufficient amounts of vitamin K results in a tendency for spontaneous bleeding or in prolonged and excessive bleeding with trauma or injury. Vitamin K deficiency occurs also in newborn infants, as well as in people treated with certain **antibiotics**. The protein in the body most affected by vitamin K deficiency is a blood-clotting protein called prothrombin.

Description

Vitamin K is a fat-soluble vitamin. The recommended dietary allowance (RDA) for vitamin K is 80 mg/day for an adult man, 65 mg/day for an adult woman, and 5 mg/day for a newborn infant. The vitamin K present in plant foods is called phylloquinone; while the form of the vitamin present in animal foods is called menaquinone. Both of these **vitamins** are absorbed from the diet and converted to an active form called dihydrovitamin K.

Spinach, lettuce, broccoli, brussels sprouts, and cabbage are good sources of vitamin K, containing about 8 mg vitamin K/kg food. Cow milk is also a good source of the vitamin.

A portion of the body's vitamin K is supplied by bacteria living in the intestine rather than by dietary sources.

Vitamin K plays an important role in blood clotting. Without the vitamin, even a small cut would cause continuous bleeding in the body, and **death**. Blood clotting is a process that begins automatically when any injury produces a tear in a blood vessel. The process of blood clotting involves a collection of molecules, which circulate continuously through the bloodstream. When an injury occurs, these molecules rapidly assemble and form the blood clot. The clotting factors are proteins, and include proteins called Factor II, Factor VII, Factor IX, and Factor X. Factor II is also called prothrombin. These proteins require vitamin K for their synthesis in the body. The blood-clotting process also requires a dozen other proteins that do not need vitamin K for their synthesis.

Causes and symptoms

Newborns are especially prone to vitamin K deficiency. A nursing-mother's milk is low in the vitamin; breast milk can supply only about 20% of the infant's requirement. Infants are born with low levels of vitamin K in their body; they do not have any vitamin K-producing bacteria in their intestines. Their digestive tracts are sterile. As a result, a form of vitamin K deficiency, called hemorrhagic disease of the newborn, may develop. This disease involves spontaneous bleeding beneath the skin or elsewhere in the infant's body, and occurs in about 1% of all infants. In rare cases, it causes death due to spontaneous bleeding in the brain.

Vitamin K deficiency in adults is rare. When it occurs, it is found in people with diseases that prevent the absorption of fat. These diseases include **cystic fibrosis**, **celiac disease**, and **cholestasis**. Vitamin K deficiency can exist in adults treated with antibiotics

KEY TERMS

Fat-soluble vitamin—Fat-soluble vitamins can be dissolved in oil or in melted fat.

Hemorrhage—Bleeding that continues for an abnormally long period of time.

Phylloquinone—An alternate name for vitamin K_1.

Prothrombin—Prothrombin is a blood-clotting protein. Injury to a blood vessel produces a signal which triggers the conversion of prothrombin to thrombin. Thrombin is a protein which plays a central role in provoking the assembly of other proteins to form the blood clot.

Recommended Dietary Allowance (RDA)—The Recommended Dietary Allowances (RDAs) are quantities of nutrients in the diet that are required to maintain good health in people. RDAs are established by the Food and Nutrition Board of the National Academy of Sciences and may be revised every few years. A separate RDA value exists for each nutrient. The RDA values refer to the amount of nutrient expected to maintain good health in people. The actual amounts of each nutrient required to maintain good health in specific individuals differ from person to person.

Water-soluble vitamins—Water-soluble vitamins can be dissolved in water or juice.

that kill the bacteria that normally live in the digestive tract. As mentioned, the intestine-bacteria supply part of our daily requirement of vitamin K. Vitamin K deficiency can result in bleeding gums, and in skin that is easily bruised.

Others who may benefit from supplemental vitamin K include those taking medications that interact with it or deplete the supply. It also appears to have some effectiveness in preventing **osteoporosis**, but some studies done involved patients using a high dietary intake of the vitamin rather than supplements. In 2003, however, a group of Japanese researchers reported that supplemental doses of vitamin K_2 given together with vitamin D_3 appeared to reduce bone turnover and sustain bone density in postmenopausal women with mild osteoporosis.

Chronically low levels of vitamin K are correlated with higher risk of hip fracture in older men and women. A study done in 2003 reported that the current recommended dietary intake for vitamin K in adults may not be adequate for older women.

Diagnosis

Vitamin K status is measured by the **prothrombin time** test. The normal prothrombin time is about 13 seconds. With vitamin K deficiency, the prothrombin time can be several minutes. The test involves taking a sample of blood, placing it in a machine called a fibrometer, and measuring the time it takes for blood-clot formation. Blood-clotting problems can also be caused by a rare genetic disease called **hemophilia**. Hemophilia is not related to vitamin K deficiency. Once vitamin K deficiency is suspected, further tests must be used to distinguish it from possible hemophilia. Where a bleeding disorder can be corrected by vitamin K treatment, the diagnosis of vitamin K deficiency is proven to be correct.

Treatment

Vitamin K deficiency in newborn infants is treated and prevented with a single injection of phylloquinone (5 mg). Adults with vitamin K deficiency are treated with daily oral doses of 10 mg phylloquinone for one week.

Prognosis

The prognosis for correcting vitamin K deficiency, and associated blood-clotting problems, is excellent.

Prevention

Aside from newborns and young infants, vitamin K deficiency is not a concern for the general population. Vitamin K deficiency can be prevented by assuring that the diet contains such foods as spinach, cabbage, brussels sprouts, and eggs. Soybean oil, canola oil, and olive oil are good sources of the vitamin, while corn oil and peanut oil are very poor sources. Elderly people, especially those living alone, should be checked for adequate intake of the vitamin.

Vitamin poisoning *see* **Vitamin toxicity**

Vitamin tests

Definition

Vitamin tests measure the levels of certain **vitamins** in an individual's blood. They are generally used to aid in the diagnosis of vitamin deficiencies or in detecting toxic amounts of a vitamin in a patient's system.

Purpose

Vitamins are components of food that are needed for growth, reproduction, and maintaining good health. The vitamins include vitamin D, vitamin E, vitamin A, and vitamin K, which are the fat-soluble vitamins, and folate, vitamin B_{12}, biotin, vitamin B_6, niacin, thiamin, riboflavin, pantothenic acid, and ascorbic acid, which are the water-soluble vitamins. Vitamins are required in the diet in only tiny amounts, in contrast to the energy components of the diet, such as sugars, starches, and fats. However, not receiving sufficient quantities of a certain vitamin can be devastating, resulting in vitamin deficiency diseases such as **scurvy**, **pellagra**, or **rickets**. Conversely, consuming too much of a certain vitamin can be toxic to a person's system. Vitamin tests are used to assess the level of certain vitamins in an individual's blood so that doctors can more accurately diagnose vitamin deficiency diseases or vitamin overdoses and devise effective therapy. The vitamins that are most commonly measured by doctors are folate, vitamin B_{12}, vitamin K, vitamin D, and vitamin A.

Description

Most of the vitamin tests are conducted by acquiring a sample of blood, and then preparing plasma or serum from the blood sample. Each vitamin occurs at extremely small concentrations when compared to levels of most other molecules in the blood. Blood contains a great number of chemicals and molecules, and many of these tend to interfere with the vitamin tests. For this reason, a procedure that separates the vitamin from contaminating substances is usually performed immediately prior to conducting the actual test. Most laboratories use high pressure liquid chromatography (HPLC), also called high performance liquid chromatography, as this purification step. In HPLC, the sample is pumped at high pressure through a tube lined with an absorbent material, to which the different molecules cling at different rates. Following separation or purification by HPLC, the vitamin is detected by a color reaction or fluorescence reaction. In these reactions, the amount of color or fluorescence that is formed is proportional to the amount of vitamin in the sample, allowing the analyst to calculate the amount of vitamin present in the original sample. In the case of some vitamins, the purified vitamin is reacted with a special chemical (reagent) prior to detection.

Levels of some vitamins may be measured indirectly by a biological test that mimics the actual function of the vitamin in the body. Riboflavin status is often measured by a test in which the rate by which a certain enzyme converts one molecule into another indicates how much Vitamin B_2 is present in a person's blood. Vitamin K is often measured by a test that times how long it takes for a spontaneous blood clot to form in a prepared sample. Vitamin E status is often measured by placing the red blood cells in a test tube, adding hydrogen peroxide, and assessing the resulting breakdown of the red blood cells. When a **vitamin E deficiency** exists, the red blood cells have a greater tendency to break.

Preparation

Most vitamin tests require no preparation; however, some may require that the patient fast for at least eight hours before giving a blood sample, or stop using some medications.

Normal results

The values that are considered to be normal for each vitamin can vary slightly. This variability can arise from different testing machines or from different

types of chemistry that are used in conducting the vitamin assays. In interpreting data on plasma vitamin levels, it should also be noted that different normal ranges may exist for different age groups and genders. For example, the normal range for plasma vitamin B_6 is 7–52 nanograms per milliliter (ng/mL) for males and 2–26 ng/mL for females.

The normal ranges for levels of certain vitamins are as follows. Please note that, by convention, the units referring to the levels of each of the vitamins may differ from each other. The units picogram/milliliter (pg/mL), nanogram/milliliter (ng/mL), and micrograms per deciliter (micrograms/dL) refer to the weight of vitamin in the specified volume. The units nanomoles/liter (nmol/L) and micromoles/liter (M/L) refer to the concentration of vitamin in the specified volume.

- folate (folic acid): 3.1–18.0 ng/mL
- vitamin B_{12}: 200–1100 pg/mL
- thiamin: 9–44 nmol/L
- riboflavin: 6.2–39 nmol/L
- vitamin B_6: 7–52 ng/mL
- vitamin C (asorbic acid): 28–84 M/L
- vitamin A: 28–94 micrograms/dL
- vitamin D (25-hydroxy-vitamin D): 25–50 ng/mL
- vitamin K: 80–1160 pg/mL

Abnormal results

In all cases, abnormal results fall below or above the normal concentration range. However, values that are considered to be borderline or severely abnormal can differ according to the discretion of the medical laboratory or physician.

Vitamin toxicity

Definition

Vitamin toxicity is a condition in which a person develops symptoms as side effects from taking massive doses of **vitamins**. Vitamins vary in the amounts that are required to cause toxicity and in the specific symptoms that result. Vitamin toxicity, which is also called hypervitaminosis or vitamin **poisoning**, is becoming more common in developed countries because of the popularity of vitamin supplements. Many people treat themselves for minor illnesses with large doses (megadoses) of vitamins.

Description

Overview

Vitamins are organic molecules in food that are needed in small amounts for growth, reproduction, and the maintenance of good health. Some vitamins can be dissolved in oil or melted fat. These fat-soluble vitamins include vitamin D, vitamin E, vitamin A (retinol), and vitamin K. Other vitamins can be dissolved in water. These water-soluble vitamins include folate (**folic acid**), vitamin B_{12}, biotin, vitamin B_6, niacin, thiamin, riboflavin, pantothenic acid, and vitamin C (ascorbic acid). Taking too much of any vitamin can produce a toxic effect. Vitamin A and vitamin D are the most likely to produce hypervitaminosis in large doses, while riboflavin, pantothenic acid, biotin, and vitamin C appear to be the least likely to cause problems.

Vitamins in medical treatment

Vitamin supplements are used for the treatment of various diseases or for reducing the risk of certain diseases. For example, moderate supplements of folic acid appear to reduce the risk for certain **birth defects** (neural tube defects) and possibly reduce the risk of **cancer**. Therapy for diseases brings with it the risk for irreversible vitamin toxicity only in the case of vitamin D. This vitamin is toxic at levels which are only moderately greater than the recommended dietary allowance (RDA). Niacin is commonly used as a drug for the treatment of heart disease. Niacin is far less toxic than vitamin D. Vitamin toxicity is not a risk with medically supervised therapy using any of the other vitamins.

Vitamin megadoses

With the exception of folic acid supplements, the practice of taking vitamin supplements by healthy individuals has little or no relation to good health. Most adults in the United States can obtain enough vitamins by eating a well-balanced diet. It has, however, become increasingly common for people to take vitamins at levels far greater than the RDA. These high levels are sometimes called vitamin megadoses. Megadoses are harmless for most vitamins. But in the cases of a few of the vitamins—specifically vitamin D, vitamin A, and vitamin B_6—megadoses can be harmful or fatal. Researchers have also started to look more closely at

megadoses of vitamin C and of vitamin E, since indirect evidence suggests that these two vitamins may reduce the risks of cancer, heart disease, and **aging**. It is not yet clear whether megadoses of either of these vitamins have any influence on health. Some experts think that megadoses of vitamin C may protect people from cancer. On the other hand, other researchers have gathered indirect evidence that vitamin C megadoses may cause cancer.

Causes and symptoms

Fat-soluble vitamins

VITAMIN D. Vitamin D and vitamin A are the most toxic of the fat-soluble vitamins. The symptoms of vitamin D toxicity are **nausea**, **vomiting**, **pain** in the joints, and loss of appetite. The patient may experience **constipation** alternating with **diarrhea**, or have **tingling** sensations in the mouth. The toxic dose of vitamin D depends on its frequency. In infants, a single dose of 15 mg or greater may be toxic, but it is also the case that daily doses of 1.0 mg over a prolonged period may be toxic. In adults, a daily dose of 1.0–2.0 mg of vitamin D is toxic when consumed for a prolonged period. A single dose of about 50 mg or greater is toxic for adults. The immediate effect of an overdose of vitamin D is abdominal cramps, **nausea and vomiting**. Toxic doses of vitamin D taken over a prolonged period of time result in irreversible deposits of **calcium** crystals in the soft tissues of the body that may damage the heart, lungs, and kidneys.

VITAMIN A. Vitamin A toxicity can occur with long-term consumption of 20 mg of retinol or more per day. The symptoms of vitamin A overdosing include accumulation of water in the brain (**hydrocephalus**), **vomiting**, tiredness, constipation, bone pain, and severe headaches. The skin may acquire a rough and dry appearance, with hair loss and brittle nails. Vitamin A toxicity is a special issue during **pregnancy**. Expectant mothers who take 10 mg vitamin A or more on a daily basis may have an infant with birth defects. These birth defects include abnormalities of the face, nervous system, heart, and thymus gland. It is possible to take in toxic levels of vitamin A by eating large quantities of certain foods. For example, about 30 grams of beef liver, 500 grams of eggs, or 2,500 grams of mackerel would supply 10 mg of retinol. The livers of polar bears and other arctic animals may contain especially high levels of vitamin A.

VITAMIN E. Megadoses of vitamin E may produce headaches, tiredness, double vision, and diarrhea in humans. Studies with animals fed large doses of vitamin E have revealed that this vitamin may interfere with the absorption of other fat-soluble vitamins. The term absorption means the transfer of the vitamin from the gut into the bloodstream. Thus, large doses of vitamin E consumed over many weeks or months might result in deficiencies of vitamin D, vitamin A, and vitamin K.

VITAMIN K. Prolonged consumption of megadoses of vitamin K (menadione) results in anemia, which is a reduced level of red blood cells in the bloodstream. When large doses of menadione are given to infants, they result in the deposit of pigments in the brain, nerve damage, the destruction of red blood cells (hemolysis), and **death**. A daily injection of 10 mg of menadione into an infant for three days can kill the child. This tragic fact was discovered during the early days of vitamin research, when newborn infants were injected with menadione to prevent a disease known as hemorrhagic disease of the newborn. Today a different form of vitamin K is used to protect infants against this disease.

Water-soluble vitamins

FOLATE. Folate occurs in various forms in food. There are over a dozen related forms of folate. The folate in oral vitamin supplements occurs in only one form, however—folic acid. Large doses of folic acid (20 grams/day) can result in eventual kidney damage. Folate is considered, however, to be relatively nontoxic, except in cases where folate supplementation can lead to **pernicious anemia**.

VITAMIN B_{12}. Vitamin B_{12} is important in the treatment of pernicious anemia. Pernicious anemia is more common among middle-aged and older adults; it is usually detected in patients between the ages of 40 and 80. The disease affects about 0.1% of all persons in the general population in the United States, and about 3% of the elderly population. Pernicious anemia is treated with large doses of vitamin B_{12}. Typically, 0.1 mg of the vitamin is injected each week until the symptoms of pernicious anemia disappear. The patient then takes oral doses of vitamin B_{12} for the rest of his or her life. Although vitamin B_{12} toxicity is not an issue for patients being treated for pernicious anemia, treatment of these patients with folic acid may cause problems. Specifically, pernicious anemia is often first detected because the patient feels weak or tired. If the anemia is not treated, the patient may suffer irreversible nerve damage. The problem with folic acid supplements is that the folic acid treatment prevents the anemia from developing, but allows the eventual nerve damage to occur.

KEY TERMS

Absorption—The transfer of a vitamin from the digestive tract to the bloodstream.

Ascorbic acid—Another name for vitamin C.

Hypercalcemia—Hypercalcemia is a condition marked by abnormally high levels of calcium in the blood. It is an issue during vitamin D toxicity.

Hypervitaminosis—Another name for vitamin toxicity.

Megadose—A very large dose of a vitamin, taken by some people as a form of self-medication.

Menadione—A synthetic form of vitamin K. It is sometimes called vitamin K_3.

Recommended Dietary Allowance (RDA)—The recommended dietary allowances (RDAs) are the quantities of nutrients in the diet that are needed for good health. RDAs are established by the Food and Nutrition Board of the National Academy of Sciences and may be revised every few years.

Retinol—Another name for vitamin A.

VITAMIN B_6. Vitamin B_6 is clearly toxic at doses about 1,000 times the RDA. Daily doses of 2–5 grams of one specific form of this vitamin can produce difficulty in walking and tingling sensations in the legs and soles of the feet. Continued megadoses of vitamin B_6 result in further unsteadiness, difficulty in handling small objects, and **numbness** in the hands. When the high doses are stopped, recovery begins after two months. Complete recovery may take two to three years.

VITAMIN C. The RDA for vitamin C in adults is 60 mg per day. Large doses of vitamin C are considered to be toxic in persons with a family history of or tendency to form **kidney stones** or gallbladder stones. Kidney and gallbladder stones usually consist of calcium oxalate. Oxalate occurs in high concentrations in foods such as cocoa, chocolate, rhubarb, and spinach. A fraction of the vitamin C in the body is normally broken down in the body to produce oxalate. A daily supplement of 3.0 grams of vitamin C has been found to double the level of oxalate that passes through the kidneys and is excreted into the urine.

NIACIN. The RDA for niacin is 15–19 mg per day in adults. Niacin comes in two forms, nicotinic acid and nicotinamide. Either form can satisfy the adult requirement for this vitamin. Nicotinic acid, however, is toxic at levels of 100 times the RDA. It can cause flushing of the skin, nausea, diarrhea, and liver damage. Flushing is an increase in blood passing through the veins in the skin, due to the dilation of arteries passing through deeper parts of the face or other parts of the body. In spite of the side effects, however, large doses of nicotinic acid are often used to lower blood cholesterol in order to prevent heart disease. Nicotinic acid results in a lowering of LDL-cholesterol ("bad cholesterol"), an increase in HDL-cholesterol ("good cholesterol"), and a decrease in plasma **triglycerides**. Treatment involves daily doses of 1.5–4.0 grams of nicotinic acid per day. Flushing of the skin occurs as a side effect when nicotinic acid therapy is started, but may disappear with continued therapy.

Diagnosis

The diagnosis of vitamin toxicity is usually made on the basis of the patient's dietary or medical history. Questioning the patient about the use of vitamin supplements may shed light on some of his or her physical symptoms. With some vitamins, the doctor can confirm the diagnosis by ordering blood or urine tests for specific vitamins. When large amounts of water-soluble vitamins are consumed, a large fraction of the vitamin is absorbed into the bloodstream and promptly excreted into the urine. Fat-soluble vitamins are more likely to be absorbed into the bloodstream and deposited in the fat and other tissues. In the cases of both water-soluble and fat-soluble vitamins, any vitamin not absorbed by the intestines is excreted in the feces. Megadoses of many of the vitamins produce diarrhea because the non-absorbed nutrient draws water out of the body and into the gut, resulting in the loss of this water from the body.

Treatment

In all cases, treatment of vitamin toxicity requires discontinuing vitamin supplements. Vitamin D toxicity needs additional action to reduce the calcium levels in the bloodstream because it can cause abnormally high levels of plasma calcium (**hypercalcemia**). Severe hypercalcemia is a medical emergency and may be treated by infusing a solution of 0.9% **sodium** chloride into the patient's bloodstream. The infusion consists of two to three liters of salt water given over a period of one to two days.

Prognosis

The prognosis for reversing vitamin toxicity is excellent for most patients. Side effects usually go away as soon as overdoses are stopped. The exceptions are severe vitamin D toxicity, severe vitamin A toxicity, and severe vitamin B_6 toxicity. Too much vitamin D leads to deposits of calcium salts in the soft tissue of the body, which cannot be reversed. Birth defects due to vitamin A toxicity cannot be reversed. Damage to the nervous system caused by megadoses of vitamin B_6 can be reversed, but complete reversal may require a recovery period of over a year.

Prevention

Vitamin toxicity can be prevented by minimizing the use of vitamin supplements. If vitamin D supplements are being used on a doctor's orders, vitamin toxicity can be prevented by monitoring the levels of plasma calcium. The development of hypercalcemia with vitamin D treatment indicates that the patient is at risk for vitamin D toxicity.

Vitamins

Definition

Vitamins are organic components in food that are needed in very small amounts for growth and for maintaining good health. The vitamins include vitamin D, vitamin E, vitamin A, and vitamin K, or the fat-soluble vitamins, and folate (**folic acid**), vitamin B_{12}, biotin, vitamin B_6, niacin, thiamin, riboflavin, pantothenic acid, and vitamin C (ascorbic acid), or the water-soluble vitamins. Vitamins are required in the diet in only tiny amounts, in contrast to the energy components of the diet. The energy components of the diet are sugars, starches, fats, and oils, and these occur in relatively large amounts in the diet.

Most of the vitamins are closely associated with a corresponding vitamin deficiency disease. **Vitamin D deficiency** leads to diseases of the bones, such as **osteoporosis** and **rickets**. **Vitamin E deficiency** occurs only rarely, and causes nerve damage. **Vitamin A deficiency** is common throughout the poorer parts of the world, and causes night blindness. Severe vitamin A deficiency can result in xerophthalamia, a disease which, if left untreated, results in total blindness. **Vitamin K deficiency** results in spontaneous bleeding. Mild or moderate folate deficiency is common throughout the world, and can result from the failure to eat green, leafy vegetables or fruits and fruit juices. Folate deficiency causes megaloblastic anemia, which is characterized by the presence of large abnormal cells called megaloblasts in the circulating blood. The symptoms of megaloblastic anemia are tiredness and weakness. Vitamin B_{12} deficiency occurs with the failure to consume meat, milk or other dairy products. Vitamin B_{12} deficiency causes megaloblastic anemia and, if severe enough, can result in irreversible nerve damage. Niacin deficiency results in **pellagra**. Pellagra involves skin **rashes** and scabs, **diarrhea**, and mental depression.

Essential vitamins

Vitamin	Benefits
Vitamin A (beta carotene)	Promotes growth and repair of body tissues; reduces susceptibility to infections; aids in bone and teeth formation; maintains smooth skin
Vitamin B_1 (thiamin)	Promotes growth and muscle tone; aids in the proper functioning of the muscles, heart, and nervous system; assists in digestion of carbohydrates
Vitamin B_2 (riboflavin)	Maintains good vision and healthy skin, hair, and nails; assists in formation of antibodies and red blood cells; aids in carbohydrate, fat, and protein metabolism
Vitamin B_3 (niacin)	Reduces cholesterol levels in the blood; maintains healthy skin, tongue, and digestive system; improves blood circulation; increases energy
Vitamin B_5 (pantothenic acid)	Fortifies white blood cells; supports the body's resistance to stress; builds cells
Vitamin B_6 (pyridoxine)	Aids in the synthesis and breakdown of amino acids and the metabolism of fats and carbohydrates; supports the central nervous system; maintains healthy skin
Vitamin B_7 (biotin)	Aids in the metabolism of proteins and fats; promotes healthy skin
Vitamin B_{12} (cobalamin)	Promotes growth in children; prevents anemia by regenerating red blood cells; aids in the metabolism of carbohydrates, fats, and proteins; maintains healthy nervous system
Folic acid (folate; considered a B-complex vitamin)	Promotes the growth and reproduction of body cells; aids in the formation of red blood cells and bone marrow
Vitamin C (ascorbic acid)	One of the major antioxidants; essential for healthy teeth, gums, and bones; helps to heal wounds, fractures, and scar tissue; builds resistance to infections; assists in the prevention and treatment of the common cold; prevents scurvy
Vitamin D	Improves the absorption of calcium and phosphorous (essential in the formation of healthy bones and teeth); maintains nervous system
Vitamin E	A major antioxidant; supplies oxygen to blood; provides nourishment to cells; prevents blood clots; slows cellular aging
Vitamin K	Prevents internal bleeding; reduces heavy menstrual flow

(Table by PreMediaGlobal. Reproduced by permission of Gale, a part of Cengage Learning.)

Thiamin deficiency results in **beriberi**, a disease that can cause atrophy, weakness of the legs, nerve damage, and **heart failure**. Vitamin C deficiency results in **scurvy**, a disease that involves bleeding. Specific diseases uniquely associated with deficiencies in vitamin B_6, riboflavin, or pantothenic acid have not been found in humans, although persons who have been starving or consuming poor **diets** for several months might be expected to be deficient in most of the nutrients, including vitamin B_6, riboflavin, and pantothenic acid.

Some vitamins serve only one function in the body, while other vitamins serve a variety of unrelated functions. Therefore, some vitamin deficiencies tend to result in one type of defect, while other deficiencies result in a variety of problems.

Purpose

People are treated with vitamins for three reasons. The primary reason is to relieve a vitamin deficiency, when one has been detected. Chemical tests suitable for the detection of all vitamin deficiencies are available. The diagnosis of vitamin deficiency often is aided by visual tests, such as the examination of blood cells with a microscope, the x-ray examination of bones, or a visual examination of the eyes or skin.

A second reason for vitamin treatment is to prevent the development of an expected deficiency. Here, vitamins are administered even with no test for possible deficiency. One example is vitamin K treatment of newborn infants to prevent bleeding. Food supplementation is another form of vitamin treatment. The vitamin D added to foods serves the purpose of preventing the deficiency from occurring in persons who may not be exposed much to sunlight and who fail to consume foods that are fortified with vitamin D, such as milk. Niacin supplementation prevents pellagra, a disease that occurs in people who rely heavily on corn as the main source of food, and who do not eat much meat or milk. In general, the U.S. food supply is fortified with niacin.

A third reason for vitamin treatment is to reduce the risk for diseases that may occur even when vitamin deficiency cannot be detected by chemical tests. One example is folate deficiency. The risk for cardiovascular disease can be slightly reduced for a large fraction of the population by folic acid supplements. In addition, the risk for certain **birth defects** can be sharply reduced if certain pregnant women use folic acid supplements.

Vitamin treatment is important during specific diseases where the body's normal processing of a vitamin is impaired. In these cases, high doses of the needed vitamin can force the body to process or utilize it in the normal manner. One example is **pernicious anemia**, a disease that tends to occur in middle age or old age and impairs the absorption of vitamin B_{12}. Surveys have revealed that about 0.1% of the general population, and 2–3% of the elderly, may have the disease. If left untreated, pernicious anemia leads to nervous system damage. The disease can easily be treated with large oral daily doses of vitamin B_{12} (hydroxocobalamin) or with monthly injections of the vitamin.

KEY TERMS

Genetic disease—A genetic disease is a disease that is passed from one generation to the next, but does not necessarily appear in each generation. An example of genetic disease is Down syndrome.

Plasma—Blood consists of red and white cells, as well as other components, that float in a liquid. This liquid is called plasma.

Recommended dietary allowance (RDA)—The Recommended Dietary Allowances (RDAs) are quantities of nutrients of the diet that are required to maintain human health. RDAs are established by the Food and Nutrition Board of the National Academy of Sciences and may be revised every few years. A separate RDA value exists for each nutrient. The RDA values refer to the amount of nutrient expected to maintain health in the greatest number of people.

Serum—Serum is blood plasma with the blood clotting proteins removed. Serum is prepared by removing blood from the subject, allowing the blood naturally to form a blood clot and then using a centrifuge to remove the red blood cells and the blood clot. The blood clot takes the form of an indistinct clump.

Vitamin status—Vitamin status refers to the state of vitamin sufficiency or deficiency of any person. For example, a test may reveal that a patient's folate status is sufficient, borderline, or severely inadequate.

Vitamin supplements are widely available as over-the-counter products. Whether they work to prevent or curtail certain illnesses, particularly in people with a balanced diet, is a matter of debate and ongoing research. For example, vitamin C is not proven to prevent the **common cold**. Nevertheless millions of people take it for that reason. A physician or pharmacist can provide more information on the appropriate use of multivitamin supplements. Likewise, although vitamin supplements have been touted as a prevention for **cancer**, a 2004 report by the U.S. Preventive Services Task Force concluded that the evidence is inadequate to recommend supplementation of vitamins A, C, or E, multivitamins with folic acid, or antioxidant combinations to decrease the risk of cancer.

Precautions

Vitamin A and vitamin D can be toxic in high doses. Side effects range from **dizziness** to kidney failure. A physician or pharmacist can help with the correct use of a multivitamin supplement that contains these vitamins.

Description

Vitamin treatment usually is done in three ways: by replacing a poor diet with one that supplies the recommended dietary allowance, by consuming oral supplements, or by injections. Injections are useful for people with diseases that prevent absorption of fat-soluble vitamins. Oral vitamin supplements are especially useful for people who otherwise cannot or will not consume food that is a good vitamin source, such as meat, milk, or other dairy products. For example, a vegetarian who will not consume meat may be encouraged to consume oral supplements of vitamin B_{12}.

Treatment of genetic diseases that impair the absorption or utilization of specific vitamins may require megadoses of the vitamin throughout one's lifetime. Megadose means a level of about 10–1,000 times greater than the recommended daily allowance (RDA). Pernicious anemia, homocystinuria, and biotinidase deficiency are three examples of genetic diseases that are treated with megadoses of vitamins.

Preparation

The diagnosis of a vitamin deficiency usually involves a blood test. An overnight fast usually is recommended as preparation prior to withdrawal of the blood test so that vitamin-fortified foods do not affect the test results.

Aftercare

Response to vitamin treatment can be monitored by chemical tests, by an examination of red blood cells or white blood cells, or by physiological tests, depending on the exact vitamin deficiency.

Risks

Few risks are associated with supervised vitamin treatment. Risks depend on the vitamin and the reason why it was prescribed. Ask a physician or pharmacist about how and when to take vitamin supplements, particularly those that have not been prescribed by a physician. There are health risks associated with

taking megadoses of some vitamins, including folic acid (a B vitamin), vitamin A, and vitamin D.

Vitiligo

Definition

Vitiligo is a condition in which a loss of cells that give color to the skin (melanocytes) results in smooth, white patches in the midst of normally pigmented skin.

Description

Vitiligo is a common, often inherited disorder characterized by areas of well-defined, milky white skin. People with vitiligo may have eye abnormalities and also have a higher incidence of thyroid disease, **diabetes mellitus**, and **pernicious anemia**. Vitiligo affects about 1-2% of the world's population. It is more easily observed in sun-exposed areas of the body and in darker skin types, but it affects any area of the body and all races. Vitiligo seems to affect men and women equally, although women more frequently seek treatment for the disorder.

Vitiligo may appear as one or two well-defined white patches or it may appear over large portions of the body. Typical sites for generalized vitiligo are areas surrounding body openings, bony areas, fingers, and toes. It can begin at any age but about 50% of the time it starts before the age of 20.

Causes and symptoms

Vitiligo is a disorder with complex causes. People with vitiligo seem to inherit a genetic predisposition for the disorder, and the appearance of disorder can be brought on by a variety of precipitating causes. Many people report that their vitiligo first appeared

Loss of pigmentation is one characteristic of vitiligo, as seen on this woman's hand. *(Custom Medical Stock Photo, Inc. Reproduced by permission.)*

KEY TERMS

Autoimmune disease—A condition in which something triggers the immune system to react against and attack the body's own tissues.

Autologous transplantation—A procedure wherein the person donates blood or tissue to themselves.

Iris—The colored part of the eye.

Pernicious anemia—A disease in which red blood cells are abnormally formed due to the body's inability to absorb vitamin B_{12}.

Retina—The innermost layer of the eye, it contains the rods and cones, specialized light-sensitive cells.

following a traumatic or stressful event, such as an accident, job loss, **death** of a family member, severe **sunburn**, or serious illness. There are at least three theories about the underlying mechanism of vitiligo. One theory says nerve endings in the skin release a chemical that is toxic to the melanocytes. A second theory states that the melanocytes simply self-destruct. The third explanation is that vitiligo is a type of autoimmune disease in which the immune system targets the body's own cells and tissues.

The primary symptom of vitiligo is the loss of skin color. Hair growing from the affected skin areas also lacks color. In addition, people with vitiligo may have pigment abnormalities of the retina or iris of the eyes. A minority of patients also may have inflammation of the retina or iris, but vision is not usually impaired.

Diagnosis

The diagnosis of vitiligo is usually made by observation. Progressive, white areas found at typical sites point to a diagnosis of vitiligo. If the diagnosis is not certain, the doctor will test for other conditions which can mimic vitiligo, such as chemical leukoderma or **systemic lupus erythematosus**. If the tests rule out other conditions, vitiligo is confirmed.

Treatment

Vitiligo cannot be cured, but it can be managed. Cosmetics can be used to improve the appearance of the white areas not covered by clothing. **Sunscreens** prevent burning of the affected areas and prevent the normal skin around the patches from becoming darker. Skin creams and oral medications are available for severe cases, but they have side effects that may make them undesirable. Autologous transplantation of skin is an option for those who are severely affected. Bleaching or depigmentation of the normal skin is another option.

In addition to treating the skin, attention should be paid to the psychological well-being of the individual. Extreme cases of vitiligo can be unattractive and may affect a person's outlook and social interactions.

Prognosis

The condition is usually gradually progressive. Sometimes the patches grow rapidly over a short period, and then the condition remains stable for many years.

Prevention

No measures are currently known to prevent vitiligo.

Vitrectomy

Definition

Vitrectomy is the surgical removal of the vitreous (transparent gel that fills the eye from the iris to the retina).

Purpose

The bulk of the contents of the eyeball is a clear jelly-like substance that is susceptible to several afflictions that impair vision by damaging its transparency.

- Infections
- Injuries

KEY TERMS

Computed tomography (CT scan)—Computerized method of creating images of internal organs using x rays.

Diabetic retinopathy—Disease that damages the blood vessels in the back of the eye caused by diabetes mellitus.

Endophthalmitis—Inflammation of the eyeball.

Iatrogenic—Inadvertently caused by medical treatment.

Magnetic resonance imaging (MRI)—Computerized method of creating images of internal organs using magnetic fields.

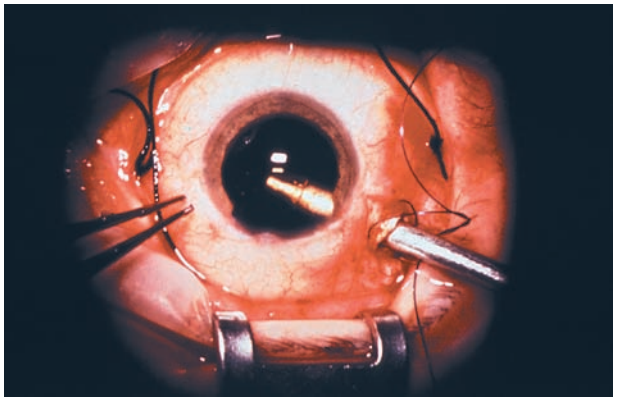
Saline—A salt solution equivalent to that in the body—0.9% salt in water.

- Bleeding, particularly from diabetic retinopathy
- Blood vessels growing into the vitreous, again due to diabetes

The retina is the light-sensitive membrane that receives images and transmits them to the brain. It covers the inside of the back of the eye. On occasion the retina will fall into the vitreous, a condition called **retinal detachment**. This may be due to disease in the vitreous that pulls the retina inward, small tears in the retina that allow liquid to seep behind it and push it forward, or injury to the eye that simply breaks the retina loose. It may be necessary to remove the vitreous in order to replace the retina and restore vision.

Description

Using instruments suited for microscopic surgery, the ophthalmologist (eye surgeon) penetrates the eyeball, aspirates the vitreous, and replaces it with saline. The saline replaces the vitreous at a constant pressure in order to keep the eye from collapsing. Once the saline is in place, both eyes are patched. The procedure takes two to three hours to complete.



Vitrectomy is a surgical procedure in which the vitreous, the transparent gel that fills the eye from the iris to the retina, is removed. During this procedure, the surgeon penetrates the eyeball with a tiny instrument (shown above), which liquefies the vitreous and suctions it out of the eye. *(Photo Researchers, Inc.)*

Preparation

Because this is a major operation on the eye, the surgeon will perform a very extensive evaluation of both eyes. After looking inside with a variety of lenses, a CT, MRI, or ultrasound study may be needed. Immediately prior to the vitrectomy, the pupils will be dilated.

Aftercare

Eye drops and **antibiotics** are administered, and eye rest is advised until healing is completed.

Risks

Risks associated with vitrectomy are retinal detachment, bleeding, iatrogenic (medically caused) **cataracts**, and endophthalmitis (inflammation of the eyeball).

Normal results

Vision is restored to useful levels in two-thirds of patients.

Vocal cord nodules and polyps

Definition

Vocal cord nodules and polyps are noncancerous growths on the vocal cords that affect the voice.

Description

The vocal cords, located in the voice box in the middle of the neck, are two tough, fibrous bands that vibrate to produce sound. They are covered with a layer of tissue that is similar to skin. With use, this layer thickens. With heavy use, the thickening may localize, producing a nodule. Unlike skin, heavy usage over a short time may also produce polyps. A polyp is a soft, smooth lump containing mostly blood and blood vessels. A nodule is similar to a polyp, but tends to be firmer.

Causes and symptoms

Chronic infections caused by **allergies** and inhalation of irritants, such as cigarette smoke, may produce these lesions, but extensive use of the voice is the most common cause of vocal nodules and polyps. Nodules and polyps are more common in male children, female adolescents, and female adults. This may be due in part to the faster speed at which the cords vibrate to produce higher-pitched voices.

Voice alterations are most apparent in singers, who may notice the higher registers are the first to change. Hoarseness causes others to seek medical attention.

Diagnosis

The head and neck surgeon (otorhinolaryngologist) must see the vocal cords to diagnose these lesions. It is also important to confirm that there are not other problems instead of or in addition to these benign lumps. Other causes of hoarseness include throat cancers, **vocal cord paralysis**, and simple **laryngitis**. The cords can usually be seen using a mirror placed at the back of the tongue. More elaborate scopes, including a videostroboscope, allow better views while the cords are producing sounds.

A biopsy of a nodule or polyp will ensure they are not cancerous.

Treatment

Nodules usually only require voice therapy; less than 5% of nodules require surgery. Small polyps can be treated with voice therapy, but typically they are surgically removed.

KEY TERMS

Laryngitis—Inflammation of the larynx (voice box).

Lesion—A wound or injury.

Otorhinolaryngologist—A physician specializing in ear, nose, and throat diseases. Also known as otolaryngologist.

Prognosis

Continued overuse of the voice will cause these lesions to regrow.

Prevention

Careful use of the voice will prevent most vocal cord nodules and polyps. Avoiding inhaled irritants may also prevent nodules and polyps from forming.

Vocal cord paralysis

Definition

Vocal cord **paralysis** is the inability to move the vocal cords and the resulting loss of vocal cord function.

Description

The vocal cords are a pair of tough, fibrous bands that lie across the air column in the middle of the voice box. They assist three functions: breathing, swallowing, and speaking. When vocal cords vibrate, they produce sound, allowing us to speak. Vocal cords temporarily stop breathing to aid coughing and for expelling **foreign objects**. During swallowing, the vocal cords shut the airway so that food is not inhaled. When vocal cords are paralyzed, all three functions are affected.

The relaxed position of the vocal cords is halfway open. There is one set of muscles that closes them all the way and one set that opens them. Each set of muscles is controlled by a different nerve. Each nerve comes from a different direction—one from above and

KEY TERMS

Computed tomography (CT scan)—Computerized use of x rays to create images of internal organs.

Laryngoscope—A diagnostic instrument that is used to examine the interior of the larynx.

Magnetic resonance imaging (MRI)—Computerized use of magnetic fields and radio-frequency signals to create images of internal organs.

Recurrent laryngeal nerve—One of two offshoots of the vagus nerve that connect to the larynx. It is located below the larynx.

Stridor—A raspy sound that occurs during respiration when the airways are blocked.

Tracheostomy—Surgical opening in the neck to the trachea to aid respiration.

Voice box—The larynx.

one from below (the recurrent laryngeal nerve). Vocal cords can either be partially paralyzed on one side or completely paralyzed on both sides.

Causes and symptoms

Vocal cord paralysis can result from injury, tumors, or surgery in the neck and upper chest. Brain tumors and **stroke** can also affect the nerves. Infectious diseases that damage nerves—like **whooping cough**, **tetanus** and polio—can also cause vocal cord paralysis. Vocal cord paralysis can also appear as a congenital defect. If congenital, the most frequent cause is a brain defect, which can often be effectively treated.

The most dangerous form of vocal cord paralysis is one that affects the opening function, controlled by the recurrent laryngeal nerve. If both vocal cords are paralyzed, breathing stops or becomes very labored. Fortunately, injury during trauma or surgery often involves only one side, but the congenital causes can damage both sides.

Vocal cord paralysis produces several symptoms.

- The voice is always affected; at best it is breathy and weak. At worst, it is not there at all. In infants, the cry can be weak. Older children will suppress laughing and coughing because it is hard to do.
- Swallowing may be hindered so that food ends up in the airway, causing violent coughing and often leading to pneumonia.
- Breathing is obstructed on aspiration, producing a condition known as stridor. Closing the airway while breathing in produces creaking noises in the throat and changes the shape of the chest. The breast bone is drawn inward, much more visibly in the flexible chest of a small child.

Diagnosis

The voice box must be observed during breathing to characterize the problem. A viewing instrument called a laryngoscope, either flexible or rigid, is passed through the nose or throat until the cords becomes visible. The motion of each cord can then be seen, and other problems in the area identified.

X rays, CT, or MRI scans of the skull may be done if a brain disorder is suspected.

Treatment

An adequate airway is immediately necessary, usually secured with an endotracheal tube in the windpipe. If a cure cannot be achieved, a permanent breathing hole (tracheostomy) is cut in the neck. Brain problems that are relieved within 24 hours usually allow the cords to regain their function. Care must be taken to assure that swallowing takes place normally.

Alternative treatment

Vocal cord paralysis can be addressed with constitutional homeopathy. This will work with the whole person, not just the symptoms, to help bring about healing. Botanical medicine and deep tissue massage to the area can also bring some resolution, although it may not be long term.

Vomiting

Definition

Vomiting is the forceful emptying or throwing up of a large portion of the stomach contents through the mouth. It can include the complete inability to hold fluids or food in the stomach. Vomiting is often accompanied or preceded by abdominal discomfort and **nausea**. **Nausea and vomiting** are also called emesis.

Demographics

Vomiting is very common, especially in the early years of life. Contagious rotaviruses are one of the most common causes of vomiting in infants and young children. Fortunately, rotavirus infection has become less prevalent in the United States since the introduction of a vaccine.

Although vomiting can stem from a variety of causes at any stage of life, **cyclic vomiting syndrome** (CVS) most often affects children. As many as one in 50 children may experience CVS, which most often begins between the ages of three and seven years. It was once thought to primarily affect girls, but CVS is now believed to be equally common in boys.

Description

Vomiting is a reflex reaction in which the abdominal muscles and diaphragm vigorously contract while the stomach is relaxed. The vomiting center in the brain triggers this reaction when it is stimulated by factors such as:

- nerve signals from the stomach and intestine that indicate irritation or swelling of the gastrointestinal tract
- chemicals in the blood, including various drugs
- psychological stimuli, such as particular sights or smells
- signals from the middle ear, as with motion sickness

Spitting up by infants, especially during the first year of life, is not considered vomiting. Spitting up is the occasional movement of small amounts of breast milk or formula from the stomach, through the esophagus, and out of the mouth, often accompanied by a burp.

Risk factors

Various medical conditions can cause vomiting. Most vomiting in children is not due to any particular risk factors. Children with CVS often have a family history of migraine and may themselves develop migraine headaches as they get older.

Causes and symptoms

Vomiting in children after the first few months of life is most often caused by **gastroenteritis** or **gastritis**. This is usually a viral infection of the gastrointestinal tract, often caused by a rotavirus. It also can be caused by **noroviruses**, enteroviruses, or adenoviruses, or bacteria or parasites. Sometimes called stomach flu, gastroenteritis usually starts with vomiting, followed by **diarrhea** within 12–24 hours. Other symptoms may include nausea, **fever**, and abdominal **pain**. Gastroenteritis is usually contagious.

Other causes of vomiting include:

- infections other than gastroenteritis, including infections of the respiratory system, urinary tract, middle ear (otitis), or membranes surrounding the brain and spinal cord (meningitis)
- a problem with infant formula
- foods that are hard to digest, such as excess sugar
- food poisoning from bacteria in undercooked meat or fish or from improperly refrigerated foods, such as *Staphylococcus* toxin in egg salad or *Bacillus cereus* toxin in rice dishes
- motion sickness
- migraine headaches
- medications, including cancer chemotherapy
- morning sickness during pregnancy

There are several serious causes of vomiting in infants:

- Pyloric stenosis is a thickening of the muscle at the end of the stomach that prevents food from entering the intestines. It causes persistent forceful vomiting of large amounts of fluid or formula within about 15–30 minutes after feeding. It is most common in infants between the ages of two weeks and four months.
- Spitting up that gradually increases during the first few weeks to months of life may indicate gastroesophageal reflux disease (GERD). GERD occurs when the muscles at the lower end of the esophagus are overly relaxed, enabling the stomach contents to back up.
- Intussusception is an intestinal obstruction in which a portion of the bowel slides into an adjacent portion. It is most common between 5 and 10 months of age and is indicated by vomiting all liquids, red-colored diarrhea, and uncontrollable crying while pulling the knees to the chest.

KEY TERMS

Appendicitis—Inflammation of the appendix—a narrow blind tube in the lower right abdomen.

Cyclic vomiting syndrome (CVS)—Episodes of severe nausea, gagging, and vomiting in children that last for hours or a day or two, repeat at regular intervals, and have no known cause.

Dehydration—Abnormal depletion of bodily fluids.

Diarrhea—Abnormally frequent bowel movements with fluid stools.

Gastroenteritis—Also called gastritis or stomach flu; inflammation of the lining of the stomach and intestines.

Gastroesophageal reflux disease; GERD—Recurrent heartburn or acid indigestion caused by leakage of the stomach contents into the esophagus.

Motion sickness—Also called kinetosis; nausea and possibly vomiting induced by motion, such as travel by car, boat, or plane.

Nausea—Stomach distress characterized by a distaste for food and the urge to vomit.

Oral rehydration solution (ORS)—Oral electrolyte maintenance solution; a balanced salt solution, containing some sugar, that replaces fluid and salts lost through vomiting and diarrhea.

Rotavirus—Any virus of the genus *Rotavirus,* some of which cause gastroenteritis.

- Appendicitis may be suggested by vomiting that persists for more than 24 hours without diarrhea.

CVS is characterized by episodes of severe nausea, gagging, and vomiting that have no known cause and last for hours or one or two days. Vomiting may occur as often as 12 times in an hour. Episodes generally begin at about the same time of day—usually late at night or upon waking in the morning. Each episode has similar symptoms and intensity levels and lasts for about the same length of time. Episodes of CVS in children are often triggered by excitement or **stress**. Children have about 12 episodes per year.

At the start of an illness that causes vomiting, especially **food poisoning**, it is common for children to vomit everything in their stomachs for three or four hours, followed by mild or moderate vomiting. Excessive vomiting, especially in combination with diarrhea, can cause dehydration—the excessive loss of body fluids. Although **dehydration** can occur at any age, young children can become dehydrated very quickly. In general, a child's risk for dehydration is:

- mild, if vomiting one to three times per day
- moderate, if vomiting 4–10 times per day
- severe, if a baby vomits continuously for 6–12 hours or a child aged two or older for 12–24 hours, especially if vomiting is accompanied by watery stool

Signs and symptoms of dehydration include:

- thirst—indicated by infant crying, irritability, and eagerly drinking
- dry mouth
- infrequent urination—less than six wet diapers per day or eight hours or more without urinating
- dark urine
- irritability
- poor appetite
- weight loss
- lack of tears when crying
- sunken soft spots on top of the head in babies under 18 months of age
- loss of springiness or elasticity of the skin
- sleepiness
- inability to drink adequate fluid

Diagnosis

Examination

Medical consultation and a **physical examination** are required if a child is vomiting and:

- may have been poisoned
- cannot retain any clear liquids
- is less than six months old
- is older than six months and has a fever above 101.4°F (38.5°C)
- has been vomiting for more than eight hours or is vomiting with increasing force
- has blood in the stool
- has blood or bile (greenish liquid) in the vomit
- has a headache and stiff neck
- is lethargic, listless, or unusually sleepy
- has severe abdominal pain or abdominal pain for more than two hours
- is very irritable
- is having convulsions
- has signs or symptoms of dehydration

Tests

Blood and/or urine tests may be performed. If a bacterial infection is suspected, a stool sample may be cultured to identify the bacteria and its susceptibility to **antibiotics**.

Procedures

If the physician suspects that the vomiting is a symptom of a serious problem in the gastrointestinal tract, x rays or other imaging procedures may be performed.

Treatment

Traditional

Vomiting is most often caused by a virus and resolves without treatment. Severe diarrhea may require the administration of intravenous (IV) fluids in a hospital. Serious underlying causes of vomiting, such as **pyloric stenosis** or **appendicitis**, may require surgery.

Drugs

Oral rehydration solution (ORS) may be required to replace fluids and nutrients lost through vomiting and diarrhea. ORS is safe for babies and older children and is readily available in grocery stores and pharmacies. It comes in various forms, including liquid, a powder to be mixed with water, and frozen popsicles. Brands include Pedialyte, Ricelyte, Rehydralyte, and the World Health Organization's Oral Rehydration Solution (WHO-ORS).

Over-the-counter and prescription remedies should not be used to treat vomiting unless specifically prescribed by a physician:

- Antiemetic drugs, such as bismuth subsalicylate (Kaopectate, Pepto-Bismol), can help relieve nausea and vomiting, but should not be given to children aged 12 or younger, or to children under 18 who may have the flu or chicken pox, because of the risk of Reye's syndrome.
- Antibiotics may be prescribed for a bacterial infection that is causing vomiting.
- Antihistamines can help prevent nausea and vomiting from motion sickness, especially if they are taken before the problem develops. They are believed to dampen the perception of motion by the middle ear and/or block nerve signals to the vomiting center in the brain. Motion sickness drugs include dimenhydrinate (Dramamine) and meclizine hydrochloride (Dramamine Less Drowsy).

Alternative

Ginger (*Zingiber officinale*) is used in Asian medicine to treat stomachaches, nausea, and diarrhea. Studies indicate that short-term use of ginger can safely treat nausea and vomiting from morning sickness and may possibly be effective for nausea from **motion sickness**, **chemotherapy**, or surgery. Ginger is available in various forms, including fresh or dried root, tablets, capsules, liquid extracts or tinctures, and teas. Ginger extract is included in many digestive, anti-nausea, cold, and flu supplements sold in the United States.

Home remedies

The correct balance of salts (electrolytes) is very important for infants. Breast milk contains the proper fluids and electrolytes. Infants who are exclusively breastfed and vomit their entire feeding more than once should be breastfed for a total of 5–10 minutes every two hours, returning to normal **breastfeeding** after vomiting has ceased for eight hours. Babies who are not exclusively breastfed should be treated with ORS—unflavored for infants under six months. Older babies can be given flavored ORS, or it can be flavored with 0.5 tsp (3 mL) of non-acidic juice. Frozen ORS pops also can be given to older babies. ORS can be made by mixing 8 tsp (48 mL) of sugar and 1 tsp (6 mL) of salt in a quart (4 cups, 0.9 L) of water. Adding a cup of orange juice to the mix or feeding the child a banana will supply needed potassium.

Vomiting infants and young children should be kept lying on their stomachs or sides as much as possible to reduce the risk of inhaling vomit into the upper airways or lungs.

Vomiting infants under one year:

- should not be given plain water unless the physician has specified an amount
- should be offered 2–3 tablespoons or up to 0.5 oz (15 mL) of ORS every 15–20 minutes with a spoon or oral syringe
- should be given an increasing amount of ORS once the solution is kept down for more than two hours, slowly increasing it over a day to the amount that is normally taken in one feeding, such as 4 oz (120 mL)
- should not be given more solution at one time than they would normally be fed, so as not to cause more vomiting
- should be reintroduced to formula slowly after at least eight hours without vomiting, beginning with frequent feedings of 0.5–1 oz (15–30 mL) for a young

infant and 1–2 oz (30–60 mL) for an infant over six months

- can be slowly returned to their normal baby cereal or soft, bland foods such as bananas, crackers, or other mild baby food
- should be slowly returned to normal feedings after not vomiting for 24 hours

Vomiting children over one year of age should be given small amounts (2 teaspoons to 2 tablespoons, up to 1 oz or 30 mL) of clear fluids every 15 minutes. Appropriate fluids include ice chips, water, ORS, or frozen ORS pops. They should not be given milk or milk products. If the child vomits again, 2 tsp (5 mL) of fluid should be given. Small amounts every few minutes may stay down better than larger amounts. Children can also be given clear soups or sodas or juice mixed with water. They should not be given dark sodas, which are usually high in sugar and can irritate the stomach. After six to eight hours without vomiting, mild, bland foods can be slowly reintroduced. Appropriate foods include saltine crackers, bread, toast, broths, mild soups, mashed potatoes, or rice. The child should not be forced to eat. After 24 hours without vomiting, a normal diet can be gradually resumed. Milk products should not be given for two to three days.

GERD can usually be controlled by:

- not overfeeding
- feeding smaller amounts more frequently
- burping frequently
- thickening milk with small amounts of baby cereal, as directed by the pediatrician
- placing the infant in a safe, quiet, upright position for at least 30 minutes after feeding

Prognosis

Children usually recover from vomiting quickly without treatment. Most children with CVS outgrow it as teenagers, although they are at increased risk for migraines as adults.

Prevention

Measures to help prevent vomiting include:

- thorough, frequent hand washing, especially before cooking and eating, after handling raw meat, and after using the toilet, to help prevent infection and food poisoning
- a healthy diet
- avoiding close contact with someone with gastroenteritis
- vaccination against rotavirus

Von Willebrand disease

Definition

Von Willebrand disease is caused by a deficiency or an abnormality in a protein called von Willebrand factor and is characterized by prolonged bleeding.

Description

The Finnish physician Erik von Willebrand was the first to describe von Willebrand disease (VWD). In 1926 Dr. von Willebrand noticed that many male and female members of a large family from the Aland Islands had increased bruising (bleeding into the skin) and prolonged episodes of bleeding. The severity of the bleeding varied between family members, ranged from mild to severe, and typically involved the mouth, nose, genital and urinary tracts, and occasionally the intestinal tract. Excessive bleeding during the menstrual period (menorrhagia) was also experienced by some of the women in this family. What differentiated this bleeding disorder from classical **hemophilia** was that it appeared not to be associated with muscle and joint bleeding and affected people of either sex rather than just men. Dr. von Willebrand named this disorder *hereditary pseudohemophilia*.

Pseudohemophilia, or von Willebrand disease (VWD) as it is now called, occurs when the body does not produce enough of a protein called von Willebrand factor(vWF) or produces abnormal vWF. vWF is involved in the process of blood clotting (coagulation). Blood clotting is necessary to heal an injury to a blood vessel. When a blood vessel is injured, vWF enables blood cells called platelets to bind to the injured area and form a temporary plug to seal the hole and stop the bleeding. vWF is secreted by platelets and by the cells that line the inner wall of the blood vessels (endothelial cells). The platelets release other chemicals, called factors, in response to a blood vessel injury that are involved in forming a strong permanent clot. vWF binds to and stabilizes factor VIII, one of the factors involved in forming the permanent clot.

A deficiency or abnormality in vWF can interfere with the formation of the temporary platelet plug and also affect the normal survival of factor VIII, which can indirectly interfere with the production of the permanent clot. Individuals with VWD, therefore, have difficulty in forming **blood clots** and as a result they may bleed for longer periods of time. In most cases the bleeding is due to an obvious injury, although it can sometimes occur spontaneously.

VWD is classified into three basic types: type 1, type 2, and type 3. The definitions of each type are based on the amount and type of vWF that is produced. Type 1 is the most common and mildest form and results when the body produces slightly decreased amounts of typically normal vWF. Type 2 can be classified into four subtypes (IIA,IIB,IIM, and IIN) and results when the body produces an abnormal type of vWF. Type 3 is the rarest and most severe form and results when the body does not produce any detectable amount of vWF.

Approximately 1 out of 100 people are affected with VWD, making it the most common inherited bleeding disorder (hemophilia). VWD affects people of all ethnic backgrounds. Approximately 70–80% of people with VWD have type 1 and close to 20–30% have type 2. Type 3 is very rare and occurs in fewer than 1% of people with VWD.

Causes and symptoms

The genetics of VWD are complex and involve a gene that produces vWF and is found on the short arm of chromosome 12. Since humans inherit two of each type of chromosome, they inherit two vWF genes. There are different types of changes (mutations) in the vWF gene that can affect the production of vWF. Some types of changes can cause the vWF gene to produce decreased amounts of normal vWF, while other changes can cause the gene to produce abnormal vWF. Most of the gene changes are significant enough that a change in only one vWF gene is sufficient to cause VWD. Some gene mutations cause VWD only if both genes are changed, which often leads to more severe symptoms.

Type 1 VWD is called an autosomal dominant condition since it is caused by a change in only one vWF gene. Since type 1 VWD results in only a slight decrease in the amount of vWF produced, the symptoms are often mild and even non-existent in some patients. Most cases of Type 2 VWD are autosomal dominant since they are caused by a change in only one vWF gene that results in the production of an abnormal protein. An autosomal dominant form of VWD can be inherited from either parent or can occur spontaneously in the embryo that is formed when the egg and sperm cells come together during fertilization.

Some cases of type 2 VWD and all cases of type 3 VWD are autosomal recessive since they are caused by

changes in both vWF genes. A person with an autosomal recessive form of VWD has inherited a changed gene from his or her mother and a changed gene from his or her father. Parents who have a child with an autosomal recessive form of VWD are called carriers, since they each possess one changed vWF gene and one unchanged vWF gene. Many carriers for the autosomal recessive forms of type 2 VWD and type 3 VWD do not have any symptoms, although some people with type 3 VWD are born to parents who have type 1 VWD and may have symptoms. Each child born to parents who are both carriers for VWD has a 25% chance of having VWD, a 50% chance of being a carrier, and a 25% chance of being neither a carrier nor affected with VWD disease. A person with an autosomal dominant form of VWD has a 50% chance of passing the changed gene on to his or her children who may or may not have symptoms.

VWD is usually a relatively mild disorder characterized by easy bruising, recurrent nosebleeds, heavy menstrual periods, and extended bleeding after surgeries and invasive dental work. There is a great deal of variability in the severity of symptoms, which can range from clinically insignificant to life-threatening. Even people within the same family who are affected with the same type of VWD may exhibit different symptoms. An individual with VWD may exhibit a range of symptoms over the course of his or her lifetime and may experience an improvement in symptoms with age. The severity of the disease is partially related to the amount and type of vWF that the body produces, but is also influenced by other genetic and non-genetic factors.

Type 1

Type 1, the mildest form of VWD, is usually associated with easy bruising, recurrent nosebleeds, heavy menstrual periods, and prolonged bleeding after surgeries and invasive work. Many people with type 1 VWD do not have any noticeable symptoms or only have prolonged bleeding after surgery or significant trauma. The amount of vWF produced by the body increases during **pregnancy**, so prolonged bleeding during delivery is uncommon in people with type 1 VWD.

Type 2

People with type 2 VWD usually have symptoms from early childhood and symptoms may even be present at birth. They usually experience prolonged bleeding from cuts, easy bruising, nose bleeds, skin hematomas, and prolonged bleeding from the gums following teeth extraction and minor trauma. More than 50% of women with type 2 VWD experience heavy periods that may require a blood **transfusion**. Gastrointestinal bleeding is rare but can be life-threatening. Some women with type 2 VWD exhibit prolonged bleeding during delivery.

Type 3

Type 3 VWD can be quite severe and is associated with bruising and bleeding from the mouth and nose, as well as intestinal, genital, and urinary tracts. Type 3 is also associated with spontaneous bleeding into the muscles and joints, which can result in joint deformities. Some women with type 3 VWD experience prolonged bleeding during delivery.

Diagnosis

Diagnostic testing

Many people with VWD have mild symptoms or symptoms that can be confused with other bleeding disorders, making it difficult to diagnose VWD on the basis of clinical symptoms. VWD should be suspected in any person with a normal number of platelets in their blood and bleeding from such mucous membranes as the nose, gums, and gastrointestinal tract. Testing for an individual with suspected VWD often includes the measurement of:

- how long it takes for the bleeding to stop after a tiny cut is made in the skin (the bleeding time)
- the amount of vWF (vWF antigen measurement)
- the activity of vWF (ristocetin co-factor activity)
- the amount of factor VIII (factor VIII antigen measurement)
- activity of factor VIII

Many doctors routinely screen women with menorrhagia for VWD, as heavy menstrual bleeding is the most common symptom of the disorder in females.

People with type 1 VWD usually have an increased **bleeding time** but they may have an intermittently normal bleeding time. They also have a decreased amount of vWF, and decreased vWF activity and usually have slightly decreased factor VIII levels and activity. People with type 2 VWD have a prolonged bleeding time, decreased activity of vWF and may have decreased amounts of vWF and factor VIII, and may have decreased factor VIII activity. Type 3 individuals have undetectable amounts of vWF, negligible vWF activity, factor VIII levels of less than 5–10%, and significantly reduced factor VIII activity. The activity of vWF is reduced for all types of VWD, making it the

most sensitive means of identifying all three types of VWD. Patients with borderline results should be tested two to three times over a three month period.

Once a patient is diagnosed with VWD, further testing such as vWF multimer analysis and ristocetin-induced platelet aggregation (RIPA) may need to be performed to determine the subtype. Multimer analysis evaluates the structure of the vWF, and RIPA measures how much ristocetin is required to cause the clumping of platelets in a blood sample. The vWF multimer analysis is able to differentiate people with a structurally normal vWF (type 1) from people with a structurally abnormal vWF (type 2) and is often able to identify the subtype of patients with type 2 VWD. People with type 1 VWD usually have normal to decreased RIPA concentrations. Depending on the subtype, patients with type 2 VWD either have increased or decreased RIPA. RIPA is usually absent and the multimer analysis shows undetectable vWF in people with type 3 VWD.

In some cases DNA testing can be a valuable adjunct to biochemical testing. The detection of gene alteration(s) can confirm a diagnosis and can determine the type and subtype of VWD. It can also help to facilitate prenatal testing and testing of other family members. Unfortunately, many people with VWD possess DNA changes that are not detectable through DNA testing. A person who has a mother, father, or sibling diagnosed with VWD should undergo biochemical testing for VWD. If the relative with VWD possesses a detectable gene change, then DNA testing should also be considered.

Prenatal testing

If one parent has been diagnosed with an autosomal dominant form of VWD or both parents are carriers for an autosomal recessive form of VWD, then prenatal testing can be considered. If the parent with an autosomal dominant form of VWD possesses a detectable gene change or both parents who are carriers for an autosomal recessive form of VWD possess detectable mutations, then DNA testing of their fetus would be available. DNA testing can be performed through **amniocentesis** or **chorionic villus sampling**. If the DNA change in the parent(s) is unknown then prenatal testing can sometimes be performed through biochemical testing of blood obtained from the fetal umbilical cord, which is less accurate and is associated with a higher risk of pregnancy loss.

Treatment

VWD is most commonly treated by replacement of vWF through the administration of blood products that contain vWF or through treatment with desmopressin (DDAVP, 1-deamino-8-D-arginine vasopressin). DDAVP functions by increasing the amount of factor VIII and vWF in the bloodstream. Treatment with blood products or DDAVP may be started in response to uncontrollable bleeding or may be administered prior to procedures such as surgeries or dental work. The type of treatment chosen depends on the type of VWD and a patient's response to a preliminary treatment trial.

Treatment with desmopressin

DDAVP is the most common treatment for people with type 1 VWD. About 80% of people with type 1 VWD respond to DDAVP therapy. Treatment with DDAVP can also be used to treat some people with type 2 VWD. Patients with Type 2B VWD should not be treated with this medication since DDAVP can induce dangerous platelet clumping. Type 3 VWD should not be treated with DDAVP since this medication does not increase the level of vWF in type 3 patients. DDAVP should only be used in people who have been shown to be responsive through a pre-treatment trial transfusion with this medication.

DDAVP can be administered intravenously or through a nasal inhaler. DDAVP has relatively few side effects although some people may experience facial flushing, **tingling** sensations, and headaches after treatment with this medication. Often treatment with this medication is only required prior to invasive surgeries or dental procedures.

Treatment with blood products

Patients who are unable to tolerate or are unresponsive to drug-based treatments are treated with concentrated factor VIII obtained from blood products. Not all factor VIII concentrates can be used since some do not contain enough vWF. The concentrate is treated to kill most viruses, although caution should be used since not all types of viruses are destroyed. If the factor VIII concentrates are unable to manage a severe bleeding episode, then blood products called cryoprecipitates, which contain concentrated amounts of vWF, or platelet concentrates should be considered. Caution should be used when treating with these blood products since they are not treated to kill viruses.

KEY TERMS

Amniocentesis—A procedure performed at 16-18 weeks of pregnancy in which a needle is inserted through a woman's abdomen into her uterus to draw out a small sample of the amniotic fluid from around the baby. Either the fluid itself or cells from the fluid can be used for a variety of tests to obtain information about genetic disorders and other medical conditions in the fetus.

Autosomal dominant—A pattern of genetic inheritance where only one abnormal gene is needed to display the trait or disease.

Autosomal recessive—A pattern of genetic inheritance where two abnormal genes are needed to display the trait or disease.

Biochemical testing—Measuring the amount or activity of a particular enzyme or protein in a sample of blood or urine or other tissue from the body.

Carrier—A person who possesses a gene for an abnormal trait without showing signs of the disorder. The person may pass the abnormal gene on to offspring.

Chorionic villus sampling (CVS)—A procedure used for prenatal diagnosis at 10–12 weeks gestation. Under ultrasound guidance a needle is inserted either through the mother's vagina or abdominal wall and a sample of cells is collected from around the early embryo. These cells are then tested for chromosome abnormalities or other genetic diseases.

Chromosome—A microscopic thread-like structure found within each cell of the body and consists of a complex of proteins and DNA. Humans have 46 chromosomes arranged into 23 pairs. Changes in either the total number of chromosomes or their shape and size (structure) may lead to physical or mental abnormalities.

Deoxyribonucleic acid (DNA)—The genetic material in cells that holds the inherited instructions for growth, development, and cellular functioning.

Desmopressin (DDAVP)—A drug used in the treatment of von Willebrand's disease.

Diagnostic testing—Testing performed to determine if someone is affected with a particular disease.

DNA testing—Analysis of DNA (the genetic component of cells) in order to determine changes in genes that may indicate a specific disorder.

Endothelial cells—The cells lining the inner walls of the blood vessels.

Factor VIII—A protein involved in blood clotting that requires vWF for stability and long-term survival in the bloodstream.

Gene—A building block of inheritance, which contains the instructions for the production of a particular protein, and is made up of a molecular sequence found on a section of DNA. Each gene is found on a precise location on a chromosome.

Menorrhagia—Excessively heavy menstrual flow with cycles of normal length. It is also called hypermenorrhea.

Mutation—A permanent change in the genetic material that may alter a trait or characteristic of an individual, or manifest as disease, and can be transmitted to offspring.

Platelets—Small disc-shaped structures that circulate in the blood stream and participate in blood clotting.

Prenatal testing—Testing for a disease, such as a genetic condition, in an unborn baby.

Protein—Important building blocks of the body, composed of amino acids, involved in the formation of body structures and controlling the basic functions of the human body.

Skin hematoma—Blood from a broken blood vessel that has accumulated under the skin.

von Willebrand factor (vWF)—A protein found in the blood that is involved in the process of blood clotting.

Other treatments and precautions

Medications called fibrinolytic inhibitors can be helpful in the control of intestinal, mouth, and nose bleeding. Estrogens such as those found in **oral contraceptives** increase the synthesis of vWF and can sometimes be used in the long-term treatment of women with mild to moderate VWD. Estrogens are also sometimes used prior to surgery in women with type 1 VWD. Some topical agents are available to treat nose and mouth bleeds.

Endometrial ablation, or the removal of the lining of the uterus by means of electrocautery or other thermal methods, is sometimes recommended as a treatment for menorrhagia associated with VWD.

This procedure appears to be successful in lowering the amount of bleeding that these women experience during their menstrual periods.

Patients with VWD should avoid taking **aspirin**, ibuprofen, or other NSAIDs, which can increase their susceptibility to bleeding. They should also inform their dentist of their diagnosis, as many routine dental procedures can cause bleeding from the gums. People with severe forms of VWD should avoid activities that increase their risk of injury such as contact sports.

Patients with type 3 VWD living in the United States may wish to contact one of the 146 federally funded Hemophilia Treatment Centers (HTCs) for advice about prophylactic treatment and general follow-up.

Prognosis

The prognosis for VWD disease is generally fairly good and most individuals have a normal lifespan. The prognosis can depend, however, on accurate diagnosis and appropriate medical treatment.

Vulvar cancer

Definition

Vulvar **cancer** refers to an abnormal, cancerous growth in the external female genitalia.

Description

Vulvar cancer is a rare disease that occurs mainly in elderly women. The vulva refers to the external female genitalia, which includes the labia, the opening of the vagina, the clitoris, and the space between the vagina and anus (perineum). There are two pairs of labia (a Latin term meaning lips). The labia meet to protect the openings of the vagina and the tube that connects to the bladder (urethra). The outer, most prominent folds of skin are called labia majora, and the smaller, inner skin folds are called labia minora. Vulvar cancer can affect any part of the female genitalia, but usually affects the labia.

Approximately 70% of vulvar cancers involve the labia (usually the labia majora), 15–20% involve the clitoris, and 15–20% involve the perineum. For approximately 5% of the cases, the cancer is present at more than one location. For approximately 10% of the cases, so much of the vulva is affected by cancer that the original location cannot be determined. Vulvar cancer can spread to nearby structures including the anus, vagina, and urethra.

Most vulvar cancers are squamous cell carcinomas. Squamous cells are the main cell type of the skin. Squamous cell carcinoma often begins at the edges of the labia majora or labia minora or the area around the vagina. This type of cancer is usually slow-growing

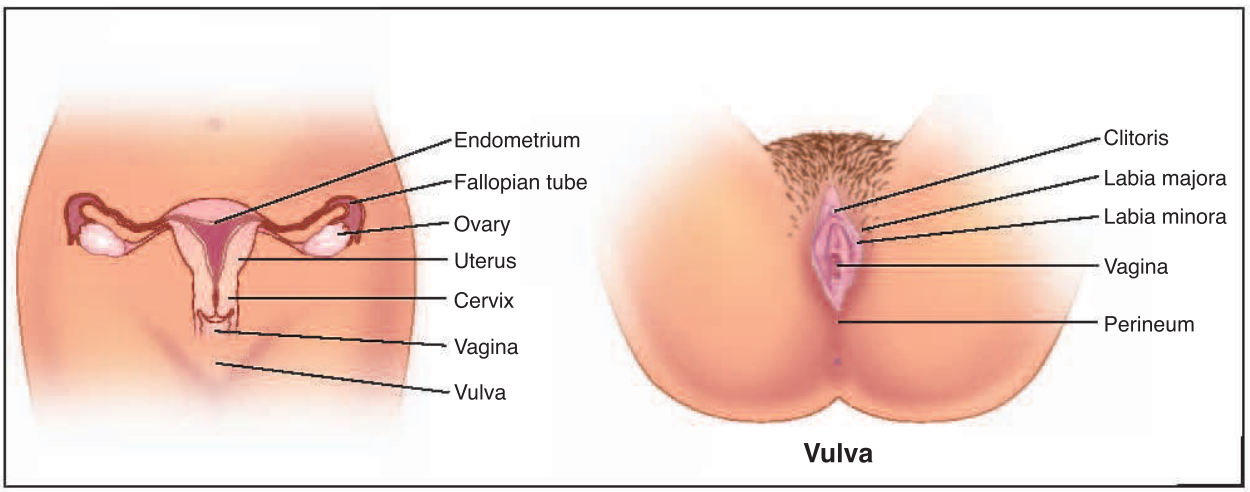

Illustration showing the female reproductive anatomy (left) and the anatomy of the vulva (right). *(Illustration by Electronic Illustrators Group. Reproduced by permission of Gale, a part of Cengage Learning.)*

and may begin with a precancerous condition referred to as vulvar intraepithelial neoplasia (VIN), or dysplasia. This means that precancerous cells are present in the surface layer of skin.

Other, less common types of vulvar cancer are melanoma, **basal cell carcinoma**, adenocarcinomas, Paget's disease of the vulva, and tumors of the connective tissue under the skin. Melanoma, a cancer that develops from the cells that produce the pigment that determines the skin's color, can occur anywhere on the skin, including the vulva. Melanoma is the second most common type of vulvar cancer, and accounts for 5–10% of the cases. Half of all vulvar melanomas involve the labia majora. Basal cell carcinoma, which is the most common type of cancer that occurs on parts of the skin exposed to the sun, very rarely occurs on the vulva. Adenocarcinomas develop from glands, including the glands at the opening of the vagina (Bartholin's glands) that produce a mucus-like lubricating fluid.

Vulvar cancer is most common in women over 50 years of age. The median age at diagnosis is 65–70 years old. Additional risk factors for vulvar cancer include having multiple sexual partners, **cervical cancer**, and the presence of chronic vaginal and vulvar inflammations. This type of cancer is often associated with **sexually transmitted diseases**.

Vulvar cancer is most common in women who are between the ages of 65 and 75 years. In the United States there are approximately 3,000 new cases of vulvar cancer diagnosed each year. Vulvar cancer accounts for only 1% of all cancers in women. Approximately 5% of all gynecologic cancers occur on the vulva. For unknown reasons, the incidence of vulvar cancer seems to be rising.

Causes and symptoms

Cancer is caused when the normal mechanisms that control cell growth become disturbed, causing the cells to continually grow without stopping. This is usually the result of damage to the DNA in the cell. Although the cause of vulvar cancer is unknown, studies have identified several risk factors for vulvar cancer. These include:

- Vulvar intraepithelial neoplasia (VIN). This abnormal growth of the surface cells of the vulva can sometimes progress to cancer.
- Infection with human papillomavirus (HPV). This virus is sexually transmitted and can cause genital warts. Although HPV DNA can be detected in most cases of vulvar intraepithelial neoplasia, it is detected in fewer than half of all cases of vulvar cancer. Therefore, the link between HPV infection and vulvar cancer is unclear. It is theorized that two classes of vulvar cancer exist: one that is associated with HPV infection and one that is not.
- Herpes simplex virus 2 (HSV2). This sexually transmitted virus is also associated with increased risk for vulvar cancer.
- Cigarette smoking. Smoking in combination with infection by HPV or HSV2 was found to be a particularly strong risk factor for vulvar cancer.
- Infection with human immunodeficiency virus (HIV). This virus, which causes AIDS, decreases

the body's immune ability, leaving it vulnerable to a variety of diseases, including vulvar cancer.

- Chronic vulvar inflammation. Long term irritation and inflammation of the vulva and vagina, which may be caused by poor hygiene, can increase the risk of vulvar cancer.
- Abnormal Pap smears. Women who have had abnormal Pap smears are at an increased risk of developing vulvar cancer.
- Chronic immunosuppression. Women who have had long-term suppression of their immune system caused by disease (such as certain cancers) or medication (such as those taken after organ transplantation) have an increased risk of developing vulvar cancer.

The hallmark symptom of vulvar cancer is **itching** (pruritus), which is experienced by 90% of the women afflicted by this cancer. The cancerous lesion is readily visible. Unfortunately, because of embarrassment or denial, it is not uncommon for women to delay medical assessment of vulvar abnormalities. Any abnormalities should be reported to a gynecologist.

If squamous cell vulvar cancer is present, it may appear as a raised red, pink, or white bump (nodule). It is often accompanied by **pain**, bleeding, vaginal discharge, and painful urination. **Malignant melanoma** of the vulva usually appears as a pigmented, ulcerated growth. Other types of vulvar cancer may appear as a distinct mass of tissue, sore and scaly areas, or cauliflower-like growths that look like **warts**.

Diagnosis

A gynecological examination will be used to observe the suspected area. During this examination, the physician may use a special magnifying instrument called a colposcope to view the area better. Additionally, the area may be treated with a dilute solution of acetic acid, which causes some abnormal areas to turn white, making them easier to see. During this examination, if any area is suspected of being abnormal, a tissue sample (biopsy) will be taken. The biopsy can be performed in the doctor's office with the use of local anesthetic. A wedge-shaped piece of tissue, which contains the suspect lesion with some surrounding normal skin and the underlying skin layers and connective tissue, will be removed. Small lesions will be removed in their entirety (excisional biopsy). The diagnosis of cancer depends on a microscopic analysis of this tissue by a pathologist.

The diagnosis for vulvar cancer will determine how advanced the cancer is and how much it has spread. This is determined by the size of the tumor and how deep it has invaded the surrounding tissue and organs, such as the lymph nodes. It will also be determined if the cancer has metastasized, or spread to other organs. Tests used to determine the extent of the cancer include x ray and computed tomography scan (CT scan). Endoscopic examination of the bladder (**cystoscopy**) and/or rectum (proctoscopy) may be performed if it is suspected that the cancer has spread to these organs.

Treatment

Clinical staging

The International Federation of Gynecology and Obstetrics (FIGO) has adopted a surgical staging system for vulvar cancer. The stage of cancer is determined after surgery. The previous clinical staging system for vulvar cancer is no longer used. Vulvar cancer is categorized into five stages (0, I, II, III, and IV) which may be further subdivided (A and B) based on the depth or spread of cancerous tissue. The FIGO stages for vulvar cancer are:

- Stage 0. Vulvar intraepithelial neoplasia.
- Stage I. Cancer is confined to the vulva and perineum. The lesion is less than 2 cm (about 0.8 in) in size.
- Stage II. Cancer is confined to the vulva and perineum. The lesion is larger than 2 cm (larger than 0.8 in) in size.
- Stage III. Cancer has spread to the vagina, urethra, anus, and/or the lymph nodes in the groin (inguinofemoral).
- Stage IV. Cancer has spread to the bladder, bowel, pelvic bone, pelvic lymph nodes, and/or other parts of the body.

Treatments

Treatment for vulvar cancer will depend on its stage and the patient's general state of health. Surgery is the mainstay of treatment for most cases of vulvar cancer.

SURGERY. The primary treatment for stage I and stage II vulvar cancer is surgery to remove the cancerous lesion and possibly the inguinofemoral lymph nodes. Removal of the lesion may be done by laser, to burn off a minimal amount of tissue, or by scalpel (local excision), to remove more of the tissue. The choice will depend on the severity of the cancer. If a large area of the vulva is removed, it is called a vulvectomy. Radical vulvectomy removes the entire vulva. A vulvectomy may require skin grafts from other areas of the body to cover the wound and make an artificial vulva. Because of the significant morbidity and the

psychosexual consequences of radical vulvectomy, there is a trend toward minimizing the extent of cancer excision. The specific inguinofemoral lymph node that would receive lymph fluid from the cancerous lesion, known as the sentinel node, may be exposed for examination (lymph node dissection) or removed (lymphadenectomy), especially in cases in which the cancerous lesion has invaded to a depth of more than 1 mm. Surgery may also be followed by **chemotherapy** and/or **radiation therapy** to kill additional cancer cells.

Surgical treatment of stage III and stage IV vulvar cancer is much more complex. Extensive surgery would be necessary to completely remove the cancerous tissue. Surgery would involve excision of pelvic organs (pelvic exenteration), radical vulvectomy, and lymphadenectomy. Because this extensive surgery comes with a substantial risk of complications, it may be possible to treat advanced vulvar cancer with minimal surgery by using radiation therapy and/or chemotherapy as additional treatment (adjuvant therapy).

An intraoperative technique that is used to identify the sentinel node in **breast cancer** and melanoma is being applied to vulvar cancer. This technique, called lymphoscintigraphy, is performed during surgical treatment of vulvar cancer and allows the surgeon to immediately identify the sentinel node. A radioactive compound (technetium 99m sulfur colloid) is injected into the cancerous lesion approximately two hours prior to surgery. This injection causes little discomfort, so **local anesthesia** is not required. During surgery, a radioactivity detector is used to locate the sentinel node and any other nodes to which cancer has spread. Although in the experimental stage, vulvar lymphoscintigraphy shows promise in reducing morbidity and hospital length of stay.

The most common complication of vulvectomy is the development of a tumor-like collection of clear liquid (wound seroma). Other surgical complications include **urinary tract infection**, wound infection, temporary nerve injury, fluid accumulation (**edema**) in the legs, **urinary incontinence**, falling or sinking of the genitals (genital prolapse), and **blood clots** (thrombus).

RADIATION THERAPY. Radiation therapy uses high-energy radiation from x rays and gamma rays to kill the cancer cells. The skin in the treated area may become red and dry and may take as long as a year to return to normal. **Fatigue**, upset stomach, **diarrhea**, and **nausea** are also common complaints of women having radiation therapy. Radiation therapy in the pelvic area may cause the vagina to become narrow as scar tissue forms. This phenomenon, known as vaginal stenosis, makes intercourse painful.

CHEMOTHERAPY. Chemotherapy uses **anticancer drugs** to kill the cancer cells. The drugs are given by mouth (orally) or intravenously. They enter the bloodstream and can travel to all parts of the body to kill cancer cells. Generally, a combination of drugs is given because it is more effective than a single drug in treating cancer. The side effects of chemotherapy are significant and include stomach upset, **vomiting**, appetite loss, hair loss, mouth or vaginal sores, fatigue, menstrual cycle changes, and **premature menopause**. There is also an increased chance of infections.

Alternative treatment

Although alternative and complementary therapies are used by many cancer patients, very few controlled studies on the effectiveness of such therapies exist. Mind-body techniques such as prayer, **biofeedback**, visualization, **meditation**, and **yoga** have not shown any effect in reducing cancer but can reduce **stress** and lessen some of the side effects of cancer treatments. Clinical studies of hydrazine sulfate found that it had no effect on cancer and even worsened the health and well-being of the study subjects. One clinical study of the drug amygdalin (Laetrile) found that it had no effect on cancer. Laetrile can be toxic and has caused **death**. Shark cartilage, although highly touted as an effective cancer treatment, is an improbable therapy that has not been the subject of clinical study.

The American Cancer Society has found that the "metabolic diets" pose serious risk to the patient. The effectiveness of the macrobiotic, Gerson, and Kelley **diets** and the Manner metabolic therapy has not been scientifically proven. The FDA was unable to substantiate the anticancer claims made about the popular Cancell treatment.

There is no evidence for the effectiveness of most over-the-counter herbal cancer remedies. However, some herbals have shown an anticancer effect. As shown in clinical studies, Polysaccharide krestin, from the mushroom *Coriolus versicolor*, has significant effectiveness against cancer. In a small study, the green alga *Chlorella pyrenoidosa* has been shown to have anticancer activity. In a few small studies, evening primrose oil has shown some benefit in the treatment of cancer.

Prognosis

Factors that are correlated with disease outcome include the diameter and depth of the cancerous lesion, involvement of local lymph nodes, cell type, HPV status, and age of the patient. Vulvar cancers

KEY TERMS

Adjuvant therapy—A treatment that is intended to aid primary treatment. Adjuvant treatments for vulvar cancer are radiation therapy and chemotherapy.

Biopsy—Removal of a small piece of tissue for microscopic examination. This is done under local anesthesia and removed by either using a scalpel or a punch, which removes a small cylindrical portion of tissue.

Colposcope—An instrument used for examination of the vagina and cervix. Part of the instrument includes a magnifying lens for better visualization.

Metastasis—The movement of cancer cells from one area of the body to another. This occurs through the blood vessels or the lymph vessels.

Pelvic exenteration—Surgical removal of the organs of the true pelvis which includes the uterus, vagina, and cervix.

Sentinel lymph node—The first lymph node to receive lymph fluid from a tumor. If the sentinel node is cancer-free, then it is likely that the cancerous cells have not metastasized.

that are HPV positive have a better prognosis than those that are HPV negative. The five-year survival rate is 98% for stage I vulvar cancer and 87% for stage II vulvar cancer. The survival rate drops steadily as the number of affected lymph nodes increases. The survival rate is 75% for patients with one or two, 36% for those with three or four, and 24% for those with five or six involved lymph nodes. The previous statistics were obtained from studies of patients who received surgical treatment only and cannot be used to determine survival rates when adjuvant therapy is employed.

Vulvar cancer can spread locally to encompass the anus, vagina, and urethra. Because of the anatomy of the vulva, it is not uncommon for the cancer to spread to the local lymph nodes. Advanced stages of vulvar cancer can affect the pelvic bone. The lungs are the most common site for vulvar cancer metastasis. Metastasis through the blood (hematogenous spread) is uncommon.

Prevention

The risk of vulvar cancer can be decreased by avoiding risk factors, most of which involve lifestyle choices. Specifically, to reduce the risk of vulvar cancer, women should not smoke and should refrain from engaging in unsafe sexual behavior. Good hygiene of the genital area to prevent infection and inflammation may also reduce the risk of vulvar cancer.

Because vulvar cancer is highly curable in its early stages, women should consult a physician as soon as a vulvar abnormality is detected. Regular gynecological examinations are necessary to detect precancerous conditions that can be treated before the cancer becomes invasive. Because some vulvar cancer is a type of skin cancer, the American Cancer Society also recommends self-examination of the vulva using a mirror. If **moles** are present in the genital area, women should employ the ABCD rule:

- Asymmetry. A cancerous mole may have two halves of unequal size.
- Border irregularity. A cancerous mole may have ragged or notched edges.
- Color. A cancerous mole may have variations in color.
- Diameter. A cancerous mole may have a diameter wider than 6 mm (1/4 in).

Vulvodynia

Definition

Vulvodynia is chronic **pain** of the vulva—the external or visible portion of the female genitalia—in the absence of vulvar or vaginal infection or skin disease. Vulvodynia is not a well-defined condition and its cause is usually unknown.

Demographics

Vulvodynia can affect any female of any age, although the onset of symptoms appears to be highest among women aged 18–25 and lowest in women over age 35. It has been estimated that at least 18% of women suffer from vulvodynia at some point in their lives. Approximately one-half of these women seek treatment. It has been estimated that about 15% of women visiting private gynecologists and about 1% of those visiting genitourinary medical clinics suffer from localized vulvodynia. Generalized vulvodynia appears to be more common in postmenopausal women and in younger women who have had back injuries.

Description

In 2003 the International Society for the Study of Vulvovaginal Disease (ISSVD) adopted a new classification system for vulvodynia: generalized vulvodynia is pain that extends beyond the vulva to other parts of the genitalia and pelvis; localized vulvodynia is pain that is restricted to the vestibule of the vulva—the region immediately surrounding the opening of the vagina and urethra. Both types of vulvodynia are further classified as:

- provoked—sexual, nonsexual, or both—depending whether the pain occurs with sex and/or with other activities
- unprovoked—pain that is constant or occurs unpredictably and is not related to specific activities
- mixed—both provoked and unprovoked

Provoked vulvodynia is pain that occurs during or after pressure is applied to the vulva. Examples of activities or factors that can provoke vulvodynia include:

- touching the vestibule
- intercourse or other sexual activity
- tampon insertion
- a gynecological exam
- urination
- sitting for a long period
- bicycle or horseback riding
- jogging or other exercise
- tight-fitting underwear or pants

Older terms for vulvodynia continue to be used. Older terms for generalized vulvodynia include dysesthetic vulvodynia and generalized vulvar dysesthesia. Older terms for localized vulvodynia include vulvar or vulval vestibulitis syndrome (VVS) and provoked vestibulodynia. Another older classification system distinguishes between organic vulvodynia, in which a cause can be identified, and essential vulvodynia, in which a cause cannot be identified. A distinction may also be made between sexually provoked primary and secondary vulvodynia, depending on whether pain occurred with a woman's first vaginal penetration or developed after a period of pain-free vaginal penetration, respectively.

As with other types of chronic pain, vulvodynia can have a significant impact on the quality of life. It may interfere with daily activities including sitting, walking, physical **exercise**, and social interactions. Sexual intercourse may be painful or impossible. Vulvodynia can lead to exhaustion and depression. In extreme cases a woman may become bedridden.

Risk factors

One study indicated that women who experienced pain when first using a tampon were seven to eight times more likely to have vulvodynia at some point in their lives. Between 10% and 25% of women with interstitial cystitis—a bladder condition that causes frequent urination with burning—also have symptoms of vulvodynia. Other possible risk factors include:

- infection of or trauma to the genitalia
- laser treatments or surgery on the external genitalia
- diabetes
- precancerous or cancerous conditions of the cervix
- a history of sexual abuse

Causes and symptoms

Although the causes of vulvodynia are unknown, there are many suggested causes, including:

- abnormalities of embryonic development
- hypersensitivity to infection
- recurrent infections
- inflammation
- rashes
- allergies or chemical irritation
- overuse of topical medications
- irritation from high oxalate levels in the urine
- genetic or inherited susceptibility to pain, chronic vestibular inflammation, or infection
- immune system factors or autoimmune responses
- injury to or irritation of vulvar or pelvic nerves or an increased nerve fiber density
- hormonal changes, including those that occur with menstrual cycles, menopause, or use of birth control pills
- pelvic floor muscle weakness or spasm

Contact or allergic **dermatitis** or chemical irritation resulting in vulvodynia can be caused by:

- soap
- shampoo
- perfume
- laundry detergent
- fabric softener
- scented or dyed toilet paper
- scented menstrual pads or tampons
- feminine hygiene products such as vulvar wipes, deodorants, or douches
- sexual lubricants
- spermicides
- some medications, particularly topical steroids
- synthetic underwear
- excessive vaginal discharge
- urine or feces

Symptoms of vulvodynia vary greatly in both type and severity. The condition usually begins suddenly and may last for months or years. The most common symptom is a painful burning sensation in the genitalia. Sometimes painful sexual intercourse is the first symptom. The pain may be intermittent or constant and localized or generalized throughout the pelvic region. Other common sensations of vulvodynia include:

- irritation
- tenderness
- stinging
- rawness or dryness
- intense itching
- soreness
- aching
- stretching of the skin in the vestibule
- throbbing
- swelling
- sharp, knife-like pain

Generalized vulvodynia is characterized by pain throughout the genitalia—not just in the vestibule—or in different areas at different times. Areas commonly affected include the:

- vestibule
- hymen
- introitus—the membranes surrounding the vaginal opening
- small or minor vestibular glands around the vaginal opening
- vulvovaginal (Batholin's) glands located on each side of the vaginal opening
- paraurethral (Skene's) glands located on each side of the urethral opening
- labia minora or inner labia
- labia majora or outer labia

Some women also experience pain in the clitoris, the perineum, the mons pubis, the anus, the inner thighs, and the lower back.

Diagnosis

Examination

A diagnosis of vulvodynia is made on the basis of pain or burning that lasts for more than three months with no apparent infection or **skin lesions**. Sometimes the vulvar tissue is inflamed, but often it appears completely normal. Other conditions that can cause chronic vulvar pain may coexist with vulvodynia and many women are misdiagnosed for years or told that they have a chronic yeast infection or a psychological disorder. It is not uncommon for women to visit at least five doctors before vulvodynia is diagnosed.

Diagnosis includes:

- a medical history
- questions about symptoms, sexual activity, diet, feminine hygiene, and medications
- an examination of the vulva and vagina for signs of infection or a skin disorder
- a pelvic examination
- use of a magnifying glass to look for abnormalities

KEY TERMS

Autoimmune response—A response in which the immune system's antibodies or T cells attack the body's own proteins, cells, or tissues.

Colposcopy—The use of a special microscope—a colposcope—to view the genitalia.

Contact dermatitis—Irritant dermatitis; direct skin contact with a substance that causes inflammation in some people.

Hymen—A membrane that partially or completely covers the vaginal opening.

Interstitial cystitis—Chronic inflammation of the bladder; sometimes associated with vulvodynia.

Labia majora—Major lips; mounds of tissue forming the lateral boundaries of the vulva.

Labia minora—Minor lips; narrow folds of tissue between the labia major, on either side of the urethral and vaginal openings.

Mons pubis—The fatty tissue over the area where the pubic bones meet.

Oxalate—A salt of oxalic acid produced during metabolism and excreted in the urine.

Perineum—The area between the external genitalia and the anus.

Vestibule—Vestibule of the vulva or vagina; the space between the labia minora containing the openings of the vagina and urethra.

Vestibulectomy—Surgical removal of the vestibule and hymen.

Vulva—The external female genitalia including the mons pubis, labia majora and minora, clitoris, vestibule, glands, and the vaginal opening.

Tests

- a "touch test" with a cotton–tipped applicator to reveal painful areas or points
- culturing of vaginal secretions to test for yeast and bacteria
- blood tests for levels of the sex hormones estrogen, progesterone, and testosterone

Procedures

A colposcopy—an examination with a special magnifying lens—may be performed to look for inflamed surface blood vessels. A tissue biopsy—the removal of a small piece of tissue for microscopic examination— may be performed, particularly if skin lesions are present.

Treatment

Traditional

There is no cure for vulvodynia. Because vulvodynia has multiple causes and symptoms vary greatly, no single treatment is appropriate for all women. Although usually treated with medications, techniques such as neurostimulation are also used. Vestibulectomy—surgical removal of the vestibule and hymen—is sometimes used as a last resort. Laser treatments to destroy the irritated tissue have not proved successful and may worsen the condition.

Drugs

Symptoms of vulvodynia may be treated with:

- creams or oral medications for yeast infections
- topical anesthetics, such as viscous or liquid five percent lidocaine ointment (Xylocaine) for temporary relief
- cortisone creams
- corticosteroid ointments, such as triamcinolone or desoximetasone
- hormone creams, such as topical estrogen or testosterone
- antihistamines, such as Atarax or Vistaril
- oral pain-blocking medications, such as tricyclic antidepressants, serotonin-norepinephrine reuptake inhibitors, or anticonvulsants
- topical compounded formulations of antidepressants or anticonvulsants
- opioid painkillers
- interferon—an antiviral drug—injected into the vulva, particularly in women who also have human papillomavirus
- a nerve block—the injection or spinal pump infusion of an anesthetic, sometimes combined with an anti-inflammatory
- trigger-point injections of a steroid or bupivacaine

Alternative

Alternative treatments for vulvodynia include:

- pelvic floor therapy—physical and exercise therapy to strengthen and relax the pelvic-floor muscles
- biofeedback with sensitive detectors designed for use on the vulva
- acupuncture
- cognitive behavioral therapy
- hypnotherapy

Home remedies

Gentle vulvar hygiene is extremely important for treating vulvodynia:

- cleaning the vulva with water only
- bathing with mild soap
- eliminating any potentially irritating products, such as douches, vaginal wipes, deodorants, bubble bath, or deodorant-containing pads or tampons
- douching with baking soda to relieve inflammation
- wearing all-cotton underwear
- avoiding tight-fitting underwear, pantyhose, and underwear at night
- applying cool gel packs to the vulvar area to reduce pain and itching
- taking cool or lukewarm sitz baths to relieve irritation and burning
- applying a compress of Aveeno—a powdered oatmeal bath treatment—to the vulva three to four times per day
- using lubrication for sexual intercourse
- aerobic exercising that does not put pressure directly on the vulva

Vulvodynia that might be caused by acidic, irritating oxalate crystals in the urine may be helped by following a low-carbohydrate, low-oxalate diet for three months to a year:

- eliminating all foods with more than 10 mg of oxalate per serving
- limiting moderate (2–10 mg per serving) oxalate-containing foods to three servings per week
- drinking 12–14 cups of water per day
- taking calcium citrate supplements without vitamin D approximately 45 minutes before eating to decrease oxalate in the urine

Prognosis

Vulvodynia sometimes disappears spontaneously and often improves over time without treatment. Although treatment—especially **corticosteroids** or the tricyclic antidepressant amitriptyline—often results in partial or complete relief of symptoms, this may take weeks, months, or even years, and some women are never completely symptom free. Vestibulectomy has the highest success rate of any treatment.

Prevention

There are numerous measures for potentially preventing or relieving symptoms of vulvodynia. These include:

- using soft, white or unbleached, unscented toilet tissue
- using 100%-cotton unscented menstrual pads and tampons
- avoiding soap and shampoo in the vulvar region
- avoiding bubble bath, feminine hygiene products, perfumed creams and soaps, petroleum jelly, and bath oils
- washing the vulva frequently with cool or lukewarm water
- drying the perineum with a hair dryer on the cool setting
- urinating before the bladder is full
- rinsing the vulva with water from a squeeze bottle after urination
- using a bidet
- eating fiber from whole grains, fruits, vegetables, and psyllium products to prevent constipation
- drinking eight glasses of water daily
- sitting on a foam rubber donut and standing periodically when sitting for long periods
- using relaxation techniques

Clothing and laundry suggestions include:

- wearing all-white cotton underwear, washing new underwear before use, and not wearing underwear at night
- wearing loose-fitting skirts and pants
- avoiding pantyhose and jeans
- wearing wicking underwear for exercise
- promptly removing wet bathing suits and exercise clothing
- washing clothes in a dermatologically approved detergent or baking soda soap
- double rinsing underwear and other clothing that contacts the vulva
- avoiding fabric softener and dryer sheets

Advice on physical activity includes:

- avoiding activities that put direct pressure on the vulva, such as bicycle and horseback riding

- limiting intense exercise that applies friction to the vulva
- applying a frozen gel pack wrapped in a towel after exercising to relieve symptoms
- performing stretching and relaxation exercises such as yoga
- avoiding hot tubs and highly-chlorinated swimming pools

Suggestions for sexual activities include:

- applying a topical anesthetic, such as 5% lidocaine gel, to the vestibule 10–15 minutes before intercourse
- applying pure almond oil, vegetable oil, or a water–soluble, glycerin-containing lubricant
- avoiding lubricants containing preservatives or other chemicals
- avoiding contraceptive creams, spermicides, and devices that may irritate the vulva
- applying ice or a frozen blue gel pack after intercourse to prevent burning
- urinating and rinsing the vulva with cool water after intercourse

Vulvovaginitis

Definition

Inflammation of the vagina and vulva most often caused by a bacterial, fungal, or parasitic infection.

Description

Vulvovaginitis, vulvitis, and vaginitis are general terms that refer to the inflammation of the vagina and/or vulva (the external genital organs of a woman). These conditions can be caused by bacterial, fungal, or parasitic infections. Also, vulvovaginitis can be caused by low estrogen levels (called "atrophic vaginitis") or any type of allergic or irritation response from things such as spermicidal products, **condoms**, soaps, and bubble bath.

In general, vulvovaginitis causes vaginal discharge, irritation, and **itching**. One of the most common reasons why women visit their doctor is because of a change in vaginal discharge. It is completely normal for a woman to have a vaginal discharge, the amount and consistency of which varies during the course of the menstrual cycle. Each of the three most common types of vulvovaginitis will be described separately.

Bacterial vaginosis

Bacterial vaginosis is the most common cause of vaginitis during the childbearing years. Forty percent to 50% of vaginitis cases are caused by bacterial vaginosis. The occurrence of bacterial vaginosis is difficult to determine but studies have proposed that 10–41% of women have had it at least once. The occurrence of bacterial vaginosis in the United States is highest among African-American women and women who have had multiple sexual partners and lowest among Asian women and women with no history of sexual contact with men. Bacterial vaginosis is not considered a sexually transmitted disease although it can be acquired by sexual intercourse.

Bacterial vaginosis is not caused by a particular organism but is a change in the balance of normal vaginal bacteria. Ninety percent of the bacteria found in a healthy vagina belong to the *Lactobacillus* family. For unknown reasons, there is a shift in the bacterial population that results in overgrowth of other bacteria. Patients suffering from bacterial vaginosis have very high numbers of such bacteria as *Gardnerella vaginalis*, *Mycoplasmahominis*, *Bacteroides* species, and *Mobiluncus* species. These bacteria can be found at numbers 100 to 1000 times greater than found in the healthy vagina. In contrast, *Lactobacillus* bacteria are in very low numbers or completely absent from the vagina of women with bacterial vaginosis.

Candida vulvovaginitis

Candida vulvovaginitis also has been called "vulvovaginal candidiasis," "candidal vaginitis," "monilial infection," or "vaginal yeast infection." Twenty to 25% of the vaginitis cases are *Candida* vulvovaginitis. It has been estimated that about 75% of all women get a vaginal yeast infection at least once. In 80–90% of the cases, *Candida* vulvovaginitis is caused by an overgrowth of the yeast *Candida albicans*. The remaining cases are caused by other species of *Candida*. It is not known what causes the yeast overgrowth. However, **antibiotics** can inadvertently kill normal bacteria in the vagina and cause an overgrowth of *Candida*.

Candida vulvovaginitis is not considered a sexually transmitted disease because *Candida* species are commonly found in the healthy vagina. It is a rare disease in girls before **puberty** and celibate women. Vaginal yeast infections tend to occur more frequently in women who are pregnant, diabetic and not controlling their disease, taking birth control pills, or taking antibiotics. The **stress** of military deployment has also been found to be a factor in triggering vaginal yeast infections. Some women have four or more attacks per year, a condition called "recurrent vaginal candidiasis."

Trichomoniasis

Trichomoniasis, which is sometimes called "trich," accounts for 15–20% of the cases of vaginitis. It is estimated that two million to three million U.S. women get trichomoniasis each year, and as many as 120 million women worldwide. Unlike the other two causes of vulvovaginitis, trichomoniasis is a sexually transmitted disease. This means that the disease is passed from person to person only by sexual contact. Trichomoniasis occurs in both men and women and is caused by infection with the single-celled parasite *Trichomonas vaginalis*. Infection with *Trichomonas vaginalis* is frequently associated with other **sexually transmitted diseases** and assists the spread of the **AIDS** virus.

Causes and symptoms

Vulvovaginitis is most often caused by a bacterial, fungal, or parasitic infection as described above. Other microorganisms may cause vulvovaginitis, or it may be caused by allergic reaction, irritation, injury, low estrogen levels, and certain diseases. Risk factors for bacterial vaginosis include using an intrauterine device (**IUD**), non-white race, prior **pregnancy**, first sexual activity at an early age, having multiple sexual partners, and having a history of sexually transmitted diseases. Persons at an increased risk for *Candida* vulvovaginitis include those who have had previous candida infections, frequent sexual intercourse, use birth control pills, have AIDS, are pregnant, are taking antibiotics or **corticosteroids**, are diabetic, use douches, use perfumed feminine hygiene sprays, wear tight clothing, or use vaginal sponges or an IUD.

The typical symptoms of vulvovaginitis are: vaginal discharge, itching, and irritation. Women may have few or no symptoms, while others may have pronounced symptoms. The main symptom of bacterial vaginosis is a fishy-smelling, thin, milky-white or gray vaginal discharge but itching and burning may also be present. The fishy smell is stronger after sexual intercourse. The symptoms of candida vulvovaginitis are itching, soreness, painful sexual intercourse, and a thick, curdy, white (like cottage cheese) vaginal discharge. Trichomoniasis symptoms are: painful urination, painful sexual intercourse, and a yellow-green to gray, foul smelling, sometimes frothy, vaginal discharge.

Diagnosis

Vulvovaginitis can be diagnosed and treated by a nurse practitioner or physician. Most insurance companies cover the costs of diagnosis and treatment. To diagnose vulvovaginitis, the doctor will examine the vagina (using a speculum to keep the vagina open) and take a sample of the vaginal discharge for tests and microscopic analysis. Laboratory culture results should be available in two to three days but the microscopic examination of the vaginal discharge may be immediately performed in the doctor's office. Diagnosis may be difficult because there are many different causes of vulvovaginitis. Women who think that they have vulvovaginitis should always visit their doctor to get an accurate diagnosis. Many women assume that they have a yeast infection and take over-the-counter medicines without first consulting their doctors.

There are four signs that indicate that a woman has bacterial vaginosis. These signs (known as Amsel's criteria) are: a thin, milky white discharge that clings to the walls of the vagina, presence of a fishy odor, a vaginal pH greater than 4.5, and the presence of clue cells in the vagina. Clue cells are vaginal cells that are covered with small bacteria. A diagnosis of candida vulvovaginitis is made after finding a normal vaginal pH (4 to 4.5) and the presence of many yeast cells in the sample of vaginal discharge or growth of yeast on laboratory media. In the spring of 2004, the U.S. Food and Drug Administration (FDA) cleared a new quick test to diagnose trichnomonas infection. The test provides results in 10 minutes. The company that manufactures the test also has a rapid result test to bacterial vaginosis. A trichomoniasis diagnosis is made when the parasites are found in the vaginal discharge either by microscopic examination or in laboratory cultures.

Trichomoniasis tends to be underdiagnosed in men because of the relative mildness of symptoms in men and insufficiently sensitive diagnostic tests. The recent introduction of DNA amplification, however, indicates that the incidence of trichomoniasis in men is much higher than was previously thought.

Treatment

Both bacterial vaginosis and trichomoniasis require prescription medication for treatment. Candida vulvovaginitis may be treated with either prescription or over-the-counter medicines. It is not advisable to take over-the-counter vaginal yeast infection medicines if one does not have a yeast infection. An Institute of Epidemiological Research survey of 390 gynecologists found that 44% of the women who were diagnosed with bacterial vaginosis had first treated themselves with over-the-counter yeast infection medications.

Bacterial vaginosis should be treated daily for one week with the antibiotics metronidazole (Flagyl, Protostat) or clindamycin (Cleocin) either as pills taken orally or in a gel or cream form put into the vagina. Trichomoniasis is treated with either a large, single dose of metronidazole or with a smaller dose taken twice daily for one week. Male sexual partners of women with trichomoniasis also must be treated.

Candida vulvovaginitis is most often treated by the application of medicated gels, creams, or suppositories applied directly to the vagina. The antifungal drugs used to treat candida vulvovaginitis include oral fluconazole (Diflucan), butoconazole (Femstat), clotrimazole (Gyne-lotrimin, Mycelex), miconazole (Monistat), and ticonazole (Vagistat). Most require only one or a few days of therapy to be effective. Women who have recurrent *Candida* infections may receive treatment for several weeks and then some form of a long-term preventive treatment.

Alternative treatment

One of the primary focuses of alternative treatment for vaginal conditions including vulvovaginitis is rebalancing the normal vaginal flora. To assist with this rebalancing, *Lactobacillus acidophilus* and *L. bifidus* are recommended, either taken internally or introduced directly into the vagina. Garlic (*Allium sativum*), both taken internally and inserted into the vagina (a peeled whole clove wrapped in gauze), may be helpful due to its antibacterial and antifungal actions. A variety of other herbs can be used as douches or in suppository form to help treat acute flare-ups of vaginal symptoms. For example a douche made by steeping 1–2 tsp. of calendula (*Calendula officinalis*) in boiling water (let the water cool before using) may help reduce inflammation. A boric acid douche can help to acidify the vaginal pH so that unwanted bacteria cannot survive and multiply. For atrophic vaginitis, especially in menopausal women, topical application of progesterone cream can help with symptoms caused by thinning of the tissue lining the vagina.

Dietary modification and nutritional supplementation may also be helpful in the treatment of vulvovaginitis. Antioxidant **vitamins**, including A, C, and E, as well as B complex vitamins, and vitamin D, are recommended. Foods to avoid include cheese, alcohol, chocolate, soy sauce, sugar, vinegar, fruits, and any fermented foods. Wearing cotton underwear, loose fitting clothes, and avoiding panty hose can help keep the vagina cool and dry, thus helping to prevent

KEY TERMS

Parasite—An animal or plant that can only survive by living inside or upon another animal or plant.

Vulva—The external genital organs of a woman, including the outer and inner lips, clitoris, and opening of the vagina.

some forms of vulvovaginitis. Cases of chronic vulvovaginitis should be addressed on systemic level by an alternative practitioner.

Prognosis

Vulvovaginitis is a disease with minor symptoms and most women respond well to medications. It is believed that certain vaginal infections, if left untreated, can lead to more serious conditions, such as **pelvic inflammatory disease**, endometritis, postsurgical infections, and spread of the AIDS virus.

Prevention

Vaginal infections may be prevented by following these suggestions:

- Over-the-counter yeast infection treatments should not be taken unless the woman had been diagnosed with candidiasis before and recognizes the symptoms.
- Douching should be avoided because it may disturb the balance of organisms in the vagina and may spread them higher into the reproductive system.
- Thoroughly dry oneself after bathing and remove a wet bathing suit promptly.
- Avoid wearing tight clothing and wear cotton underwear.
- Clean diaphragms, cervical caps, and spermicide applicators after use. Use condoms to avoid sexually transmitted disease.
- After a bowel movement, wipe from front to back to avoid spreading intestinal bacteria to the vagina.

Waldenströ disease *see* **Waldenström's macroglobulinemia**

Waldenström's macroglobulinemia

Definition

Waldenstrom's macroglobulinemia is a rare, chronic **cancer** of the immune system that is characterized by hyperviscosity, or thickening, of the blood.

Description

Waldenstrom's (Waldenstrom, Waldenstroem's) macroglobulinemia (WM) is a lymphoma, or cancer of the lymphatic system. It was first identified in 1944, by the Swedish physician Jan Gosta Waldenstrom, in patients who had a thickening of the serum, or liquid part, of the blood. Their blood serum contained a great deal of a very large molecule called a globulin. Thus, the disorder is called macroglobulinemia.

Lymphomas are cancers that originate in tissues of the lymphatic system. All lymphomas other than Hodgkin's disease, including WM, are known collectively as non-Hodgkin's lymphomas. There are 13 major types of non-Hodgkin's lymphomas and others that are very rare. Other names that are sometimes used for WM include lymphoplasmacytic lymphoma, lymphoplasmacytic leukemia, macroglobulinemia of Waldenstrom, primary macroglobulinemia, Waldenstrom's syndrome, Waldenstrom's purpura, and hyperglobulinemic purpura. Purpura refers to purple spots on the skin, resulting from the frequent bleeding and bruising that can be a symptom of WM.

WM is classified as a low-grade or indolent form of lymphoma because it is a slow-growing cancer that produces fewer symptoms than other types of lymphomas. WM most often affects males over the age of 65. Frequently, this disease produces no symptoms and does not require treatment. It has not been studied as extensively as other types of lymphoma.

The lymphatic system

The lymphatic system is part of the body's immune system for fighting disease and part of the blood-producing system. It includes the lymph vessels and nodes, spleen, bone marrow, and thymus. The narrow lymphatic vessels carry lymphatic fluid from throughout the body. The lymph nodes are small, pea-shaped organs that filter the lymphatic fluid and trap foreign substances, including viruses, bacteria, and cancer cells. The spleen, in the upper left abdomen, removes old cells and debris from the blood. The bone marrow, the spongy tissue inside the bones, produces new blood cells.

B lymphocytes or B cells are white blood cells that recognize disease-causing organisms. They circulate throughout the body in the blood and lymphatic fluid. Each B lymphocyte recognizes a specific foreign substance, or antigen. When it encounters its specific antigen, the B cell begins to divide and multiply, producing large numbers of identical (monoclonal), mature plasma cells. These plasma cells produce large amounts of antibody that are specific for the antigen. Antibodies are large proteins called immunoglobulins (Igs) that bind to and remove the specific antigen.

A type of Ig, called IgM, is part of the early immune response. The IgM molecules form clusters in the bloodstream. When these IgM clusters encounter their specific antigen, usually a bacterium, they cover it so that it can be destroyed by other immune system cells.

Plasma cell neoplasm

WM is a type of plasma cell neoplasm or B-cell lymphoma. These are lymphomas in which certain

plasma cells become abnormal, or cancerous, and begin to grow uncontrollably. In WM, the cancerous plasma cells overproduce large amounts of identical (monoclonal) IgM antibody. This IgM also is called M protein, for monoclonal or myeloma protein.

Macroglobulinemia refers to the accumulation of the M protein in the serum of the blood. This large amount of M protein can cause the blood to thicken, causing hyperviscosity. The malignant plasma cells of some WM patients also produce and secrete partial immunoglobulins called light chains, or Bence-Jones proteins. The malignant plasma cells can invade various tissues, including the bone marrow, lymph nodes, and spleen, causing these tissues to swell.

WM accounts for about 1-2% of non-Hodgkin's lymphomas. It is estimated that it may affect about five out of every 100,000 people. It usually affects people over the age of 50 and most often develops after age 65. It is more common in men than in women. In the United States, WM is more common among Caucasians than among African Americans. The disease can run in families.

Causes and symptoms

The cause of WM is not known.

Many individuals with WM have no symptoms of the disease. This is known as asymptomatic macroglobulinemia. When symptoms of WM are present, they may vary greatly from one individual to the next.

Hyperviscosity syndrome

At least 50% of individuals with WM have hyperviscosity syndrome, an increased viscosity or thickening of the blood caused by the accumulation of IgM in the serum. Hyperviscosity can cause a slowing in the circulation through small blood vessels. This condition can lead to a variety of symptoms:

- fatigue
- weakness
- rash
- bruising
- nose bleeds
- gastrointestinal bleeding
- weight loss
- night sweats
- increased and recurrent infections
- poor blood circulation in the extremities

Poor blood circulation, or Raynaud's phenomenon, can affect any part of the body, but particularly the fingers, toes, nose, and ears.

Cold weather can cause additional circulatory problems by further thickening the blood and slowing down circulation. In some cases, the excess blood protein may precipitate out of the blood in the cold, creating particles that can block small blood vessels. This is called cryoglobulinemia. The extremities may turn white, or a patchy red and white. The hands, feet, fingers, toes, ears, and nose may feel cold, numb, or painful.

Hyperviscosity may affect the brain and nervous system, leading to additional symptoms. These symptoms include:

- peripheral neuropathy, caused by changes in the nerves, leading to pain or numbness in the extremities
- dizziness
- headaches
- vision problems or loss of vision
- Mental confusion
- poor coordination
- temporary paralysis
- mental changes

Hyperviscosity can clog the tubules that form the filtering system of the kidneys, leading to kidney damage or kidney failure. Existing heart conditions can be aggravated by WM. In extreme cases, WM may result in **heart failure**. Late-stage WM also may lead to mental changes that can progress to **coma**.

Anemia

The accumulation of IgM in the blood causes an increase in the volume of the blood plasma. This effectively dilutes out the red blood cells and other blood components. The lowered concentration of red blood cells can lead to anemia and cause serious **fatigue**. Likewise, a deficiency in platelets (**thrombocytopenia**), which cause the blood to clot, can result in easy bleeding and bruising. As the cancer progresses, there may be abnormal bleeding from the gums, nose, mouth, and intestinal tract. There may be bluish discoloration of the skin. In the later stages of the disease, leukopenia, a deficiency in white blood cells, also can develop.

Organ involvement

In 5-10% of WM cases, the IgM may be deposited in tissues. Thus, some individuals with WM have enlargement of the lymph nodes, the spleen, and/or the liver.

If Bence-Jones proteins are produced by the malignant plasma cells, they may be deposited in the

kidneys. There they can plug up the tiny tubules that form the filtering system of the kidneys. This can lead to kidney damage and kidney failure.

Diagnosis

Since many individuals with WM have no symptoms, the initial diagnosis may result from blood tests that are performed for some other purpose. Blood cell counts may reveal low red blood cell and platelet levels. A **physical examination** may indicate enlargement of the lymph nodes, spleen, and/or liver. A retinal **eye examination** with an ophthalmoscope may show retinal veins that are enlarged or bleeding.

Blood and urine tests

Serum **protein electrophoresis** is used to measure proteins in the blood. In this laboratory procedure, serum proteins are separated in an electrical field, based on the size and electrical charge of the proteins. Serum **immunoelectrophoresis** uses a second antibody that reacts with IgM. A spike in the Ig fraction indicates a large amount of identical or monoclonal IgM in individuals with WM.

Normal serum contains 0.7-1.6 gm per deciliter (g/dL) of Ig, with no monoclonal Ig present. At serum IgM concentrations of 3-5 g/dL, symptoms of hyperviscosity often are present. However some individuals remain asymptomatic with IgM levels as high as 9 g/dL.

Urinalysis may indicate protein in the urine. A urine Bence-Jones protein test may indicate the presence of these small, partial Igs.

Bone marrow

Abnormal blood tests usually are followed by a **bone marrow biopsy**. In this procedure, a needle is inserted into a bone and a small amount of marrow is removed. Microscopic examination of the marrow may reveal elevated levels of lymphocytes and plasma cells. However, less than 5% of patients with WM have lytic bone lesions, caused by cancerous plasma cells in the bone marrow that are destroying healthy cells. Bone lesions can be detected with x rays.

Treatment

Clinical staging, to define how far a cancer has spread through the body, is the common method for choosing a cancer treatment. However, there is no generally-accepted staging system for WM.

There also is no generally-accepted course of treatment for WM. Treatment may not be necessary for asymptomatic macroglobulinemia. However, if IgM serum levels are very high, treatment may be initiated even in the absence of symptoms. If symptoms are present, treatment is directed at relieving symptoms and retarding the disease's development. Of major concern is the prevention or alleviation of blood hyperviscosity. Therefore, the initial treatment depends on the viscosity of the blood at diagnosis.

Hyperviscosity

Plasmapheresis, or plasma exchange **transfusion**, is a procedure for thinning the blood. In this treatment, blood is removed and passed through a cell separator that removes the plasma, containing the IgM, from the red and white blood cells and platelets. The blood cells are transfused back into the patient, along with a plasma substitute or donated plasma. Plasmapheresis relieves many of the acute symptoms of WM. Individuals with WM may be given fluid to counter the effects of hyperviscous blood.

Low blood cell counts

Treatments for low blood cell levels include:

- the drug Procrit to treat anemia
- transfusions with packed red blood cells to treat anemia in later stages of the disease
- antibiotics to treat infections caused by a deficiency in white blood cells
- transfusions with blood platelets

Chemotherapy

Chemotherapy, the use of anti-cancer drugs, helps to slow the abnormal development of plasma cells, but does not cure WM. It can reduce the amount of IgM in the bone marrow. In particular, chemotherapy is used to treat severe hyperviscosity and anemia that are caused by WM.

Chlorambucil (Leukeran), possibly in combination with prednisone, is the typical chemotherapy choice for WM. This treatment is effective in 57% of cases. These drugs are taken by mouth. Prednisone is a corticosteroid that affects many body systems. It has anti-cancer and anti-inflammatory effects and is an immune system suppressant. Other drug combinations that are used to treat WM include cyclophosphamide (Cytoxan), vincristine, and prednisone, with or without doxorubicin. Fludaribine, 2-chlorodeoxyadenosine, and **corticosteroids** also may be used.

side effects of chemotherapy may include:

- mouth sores
- nausea and indigestion
- hair loss

KEY TERMS

Anemia—Any condition in which the red blood cell count is below normal.

Antibody—Immunoglobulin produced by immune system cells that recognizes and binds to a specific foreign substance (antigen).

Antigen—Foreign substance that is recognized by a specific antibody.

Autosomal dominant—Genetic trait that is expressed when present on only one of a pair of non-sex-linked chromosomes.

B cell (B lymphocyte)—Type of white blood cell that produces antibodies.

Bence-Jones protein—Light chain of an immunoglobulin that may be overproduced in Waldenstrom's macroglobulinemia; it is excreted in the urine.

Biopsy—Removal of a small sample of tissue for examination under a microscope; used in the diagnosis of cancer.

Cryoglobulinemia—Condition in which protein in the blood forms particles in the cold, blocking blood vessels and leading to pain and numbness of the extremities.

Hyperviscosity—Thick, viscous blood, caused by the accumulation of large proteins, such as immunoglobulins, in the serum.

Immunoelectrophoresis—Use of an electrical field to separate proteins in a mixture (such as blood or urine), on the basis of the size and electrical charge of the proteins; followed by the detection of an antigen (such as IgM), using a specific antibody.

Immunoglobulin (Ig)—Antibody such as IgM; large protein produced by B cells that recognizes and binds to a specific antigen.

Interferon alpha—Potent immune-defense protein; used as an anti-cancer drug.

Lymphatic system—The vessels, lymph nodes, and organs, including the bone marrow, spleen, and thymus, that produce and carry white blood cells to fight disease.

Lymphoma—Cancer that originates in lymphatic tissue.

M protein—Monoclonal or myeloma protein; IgM that is overproduced in Waldenstrom's macroglobulinemia and accumulates in the blood and urine.

Monoclonal—Identical cells or proteins; cells (clones) derived from a single, genetically-distinct cell, or proteins produced by these cells.

Plasma cell—Type of white blood cell that produces antibodies; derived from an antigen-specific B cell.

Plasmapheresis—Plasma exchange transfusion; the separation of serum from blood cells to treat hyperviscosity of the blood.

Platelet—Cell that is involved in blood clotting.

Stem cell—Undifferentiated cell that retains the ability to develop into any one of numerous cell types.

- increased appetite
- nervousness
- insomnia

These side effects disappear after the chemotherapy is discontinued.

The long-term management of WM usually is accomplished through a combination of plasmapheresis and chemotherapy.

Alternative and complementary therapies

Biological therapy or immunotherapy, with the potent, immune system protein interferon alpha, is used to relieve the symptoms of WM. Interferon alpha works by boosting the body's immune response. Interferon can cause flu-like symptoms, such as **fever**, chills, and fatigue. It also can cause digestive problems and may affect blood pressure.

The drug rituximab, an antibody that is active against antibody-producing cells, is effective in about 30% of individuals with WM. Rituximab is a monoclonal antibody produced in the laboratory. Monoclonal antibody treatment may cause a an allergic reaction in some people.

Prognosis

There is no cure for WM. In general, patients go into partial or complete remission following initial treatments. However the disease is not cured and follow-up treatment may be necessary.

The prognosis for this cancer depends on an individual's age, general health, and genetic (hereditary) makeup. Males, individuals over age 60, and those

with severe anemia have the lowest survival rates. The Revised European American Lymphoma (REAL) classification system gives WM a good prognosis following treatment, with an average 5-year survival rate of 50-70%. However, many people with WM live much longer, some without developing any symptoms of the disease. About 16-23% of individuals with WM die of unrelated causes.

Prevention

There is no known prevention for WM.

Warts

Definition

Warts are small, benign growths caused by a viral infection of the skin or mucous membrane. The virus infects the surface layer. The viruses that cause warts are members of the **human papilloma virus** (HPV) family. Warts are not cancerous but some strains of HPV, usually not associated with warts, have been linked with **cancer** formation. Warts are contagious from person to person and from one area of the body to another on the same person.

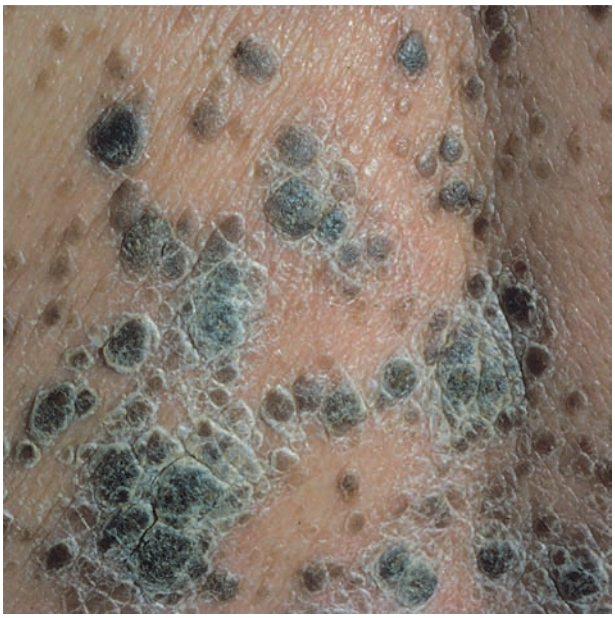
Demographics

Warts are particularly common among children, young adults, and women. They affect about 7–10 percent of the U. S. population. The incidence of **genital warts** in the United States is around one million cases annually. It is estimated that approximately one in 272 have genital warts, which is roughly 0.37% of the population.

Description

Particularly common among children, young adults, and women, warts are a problem for 7-10% of the population. There are close to 60 types of HPV that cause warts, each preferring a specific skin location. For instance, some types of HPV cause warts to grow on the skin, others cause them to grow inside the mouth, while still others cause them to grow on the genital and rectal areas. However, most can be active anywhere on the body. The virus enters through the skin and produces new warts after an incubation period of one to eight months. Warts are usually

Warts on finger. *(CMSP/Getty Images.)*



Seborrhoeic warts appearing on a patient's back. *(Custom Medical Stock Photo, Inc. Reproduced by permission.)*

skin-colored and feel rough to the touch, but they also can be dark, flat, and smooth.

Warts are passed from person to person, directly and indirectly. Some people are continually susceptible to warts, while others are more resistant to HPV and seldom get them. The virus takes hold more readily when the skin has been damaged in some way, which may explain why children who bite their nails tend to have warts located on their fingers. People who take a medication to suppress their immune system or are on long-term steroid use are also prone to a wart virus infection. This same is true for patients with **AIDS**.

Causes and symptoms

The more common types of warts include:

- common hand warts
- foot warts
- flat warts
- genital warts

Hand warts

Common hand warts grow around the nails, on the fingers, and on the backs of hands. They appear more frequently where skin is broken, such as in areas where fingernails are bitten or hangnails picked.

Foot warts

Foot warts are called plantar warts because the word plantar is the medical term for the sole of the foot, the area where the wart usually appears as a single lesion or as a cluster. Plantar warts, however, do not stick up above the surface like common warts. The ball of the foot, the heel and the plantar part of the toes are the most likely locations for the warts because the skin in those areas is subject to the most weight, pressure, and irritation, making a small break or crack more likely.

Plantar warts are familiar to all ages groups, appearing frequently in children between the ages of 12 and 16. Adolescents often come into contact with a wart virus in a locker room, swimming pool area, or by walking barefooted on dirty surfaces. The blood vessels feeding them are the black dots that are visible on the wart. If left untreated, these warts can grow to an inch or more in circumference and spread into clusters of several warts. They are known to be very painful at times, the **pain** usually compared to the feeling of a permanent stone in the shoe, particularly if the wart is on a pressure point of the foot. People with **diabetes mellitus** are prone to complications from plantar warts related to the development of sores or ulceration and the poor healing potential associated with diabetes.

Flat warts

Flat warts tend to grow in great numbers and are smaller and smoother than other warts. They can erupt anywhere, appearing more frequently on the legs of women, the faces of children, and on the areas of the face that are shaved by young adult males.

Genital warts

Genital warts, also called condyloma acuminata or venereal warts, are one of the most common causes of sexually transmitted disease (STD) in this country. According to the *Journal of the American Medical Association's* STD Information Center, they are contracted by sexual contact with an infected person who carries HPV and are more contagious than other warts. It is estimated that two-thirds of the people who have sexual contact with a partner with genital warts will develop the disease within three months of contact. As a result, about one million new cases of genital warts are diagnosed in the United States each year.

Genital warts tend to be small flat bumps or they may be thin and tall. They are usually soft and not scaly like other warts. In women, genital warts appear

on the genitalia, within the vagina, on the cervix, and around the anus or within the rectum. In men, genital warts usually appear on the tip of the penis but may also be found on the scrotum or around the anus. Genital warts can also develop in the mouth of a person who has had oral sexual contact with an infected person.

Diagnosis

Patients who notice warts in their genital area should see a doctor. The doctor may be able to diagnose the warts with a simple examination. If the warts are small, the doctor may put a vinegar-like liquid on the skin, which makes the warts turn white and easier to see, and then use a magnifying glass to look for them.

Treatment

Home/self treatment

Many of the nonprescription wart remedies available at drug stores will remove simple warts from hands and fingers. These medications may be lotions, ointments, or plasters and work by chemically removing the skin that was affected by the wart virus. The chemicals are strong, however, and should be used with care since they can remove healthy as well as infected skin. These solutions should be avoided by diabetics and those with cardiovascular or other circulatory disorders whose skin may be insensitive and not appreciate irritation.

Flat warts are best treated with topical retinoides (retinoic acid) or a gel containing salicylic acid. The acid doesn't actually kill the wart virus, but waterlogs the skin so that the surface layer, with the virus, peels off. These products can take up to three months of treatment depending on the size and depth of the wart. Patches are also good to use. Rather than applying drops, a small pad is placed on the wart and left for 48 hours and then replaced with a new one. The patch usually contains a higher concentration of salicylic acid and may irritate the surrounding skin. If this occurs, patients should switch to a gel or stop medication for a period. To help the healing process for flat facial warts, men should shave with an electric shaver or temporarily grow a beard. Women with flat warts on areas that are shaved should use other methods to remove hair, such as depilatory cream or wax.

Professional treatment

Physicians should be consulted if there are no signs of progress after a month of self treatment. Doctors have many ways of removing warts, including using stronger topically applied chemicals than those available in drugstores. Some of these solutions include podofilox, topical podophyllum, and trichloracetic acid (TCA). Some burning and discomfort for one or more days following treatment can be expected. Although these chemicals are effective, they may not destroy all warts completely. A second method of removal is freezing or cryosurgery on the wart using liquid nitrogen. **Cryotherapy** is relatively inexpensive, does not require anesthesia, and usually does not result in scarring. Although temporarily uncomfortable, it provides an effective and safe way to deliver freezing temperatures to a particular area on the skin, and healing is usually quick. Physicians may also choose to burn the wart with liquid nitrogen or numb the skin and then scrape off the wart. Another removal process is electrocautery (electric burning), destroying the wart by burning it with an electric needle. **Laser surgery** is also becoming a more common option for removing warts.

Genital warts are the most difficult to treat. They can be removed, but the viral infection itself cannot be cured. Often, because the warts are so small, more than one treatment may be needed. The virus continues to live in the deeper skin, which is why warts often return after they have been removed. Strong chemicals may be applied as well as surgical excision with or without electrocautery. This therapy requires a small operative procedure and a local anesthetic. Laser therapy, although more expensive, is often used for treating venereal warts that are more extensive. The use of lasers which vaporize the lesion can theoretically transmit the HPV. It is not at all clear, however, if this occurs.

There is no one recommended method for eliminating plantar warts. If detected early, cryotherapy is usually enough. However, they can be very resilient, requiring treatment over several months. Treatment ranges from the conservative approach of applying chemical solutions to the more aggressive option of surgery. Patients with diabetes or **vascular disease** are usually treated with the more conservative methods.

Alternative treatment

There are a variety of alternative approaches to the treatment of warts. The suggestions described below apply to common warts and plantar warts, not to genital or cervical warts. Since genital and cervial warts are transmitted sexually, they should be treated by a physician.

KEY TERMS

Condyloma acuminata—Another term for genital warts.

Cryotherapy—Freezing with liquid nitrogen for removal.

Endometritis—Inflammation of the endometrium or mucous membrane of the uterus.

Epidermis—The outer layer of human skin.

Human papilloma virus (HPV)—A family of viruses that causes hand warts, foot warts, flat warts, and genital warts.

Retinoic acid—Vitamin A_1 acid, which is used topically to treat acne.

Salicylic acid—An agent prescribed in the treatment of hyperkeratotic skin conditions and fungal infections.

For the treatment of common or plantar warts, alternative practitioners may recommend these remedies:

- Apply a paste made of vitamin C powder to the wart for one to two weeks.
- Place a crushed or sliced garlic clove over the wart for seven consecutive nights while sleeping.
- Soak the wart in water, put cross-hatches over it with a sterile needle, and apply drops of thuja (*Thuja occidentalis*) tincture onto the wart. Repeat the cross-hatching and tincture application until the wart is saturated with the tincture. Repeat several times each day for one to two weeks. (A tincture is an herbal extract made with alcohol.)
- Tape a piece of banana peel, latex side down, over the wart and leave it on overnight. Repeat nightly for one to two weeks.

Because warts are caused by a virus, general immune system support can be effective in helping to keep warts from coming back after treatment or to keep them from multiplying or growing. Eating a well balanced diet high in sources of **vitamins** A, C, and E can help strengthen the immune system. Avoiding **stress**, which is believed to compromise the immune system, is also helpful.

Prognosis

Even though genital warts may be removed, the virus itself continues to live. The HPV can cause tissue changes in the cervix of women with cervical infection. The general recommendation for women who have a history of genital warts is to see their doctors every six months for Pap smears to monitor any changes that may occur.

For plantar warts, the treatment goal is to destroy the wart and its virus without causing much damage to healthy skin. It is not unusual for treatment to cause pain until the foot heals because of the weight put on the foot.

Prevention

Genital warts can be prevented by using **condoms** and avoiding unprotected sex. Barrier protection will not, however, prevent the spread of wart-causing HPV to uncovered areas such as the pubis and upper thighs. Plantar warts can be prevented by wearing shoes, changing shoes daily, keeping feet clean and dry, and not ignoring skin growths and changes in the skin.

Wechsler intelligence test

Definition

The Wechsler Intelligence Scales are a series of standardized tests used to evaluate cognitive abilities and intellectual abilities in children and adults.

Purpose

The Wechsler Intelligence Scales for Children (regular, revised, and third edition) and Wechsler Preschool and Primary Scale of Intelligence are used as tools in school placement, in determining the presence of a learning disability or a developmental delay, in identifying giftedness, and in tracking intellectual development.

The Wechsler Adult Intelligence Scales (regular and revised) are used to determine vocational ability, to assess adult intellectual ability in the classroom, and to determine organic deficits. Both adult and children's Wechsler scales are often included in neuropsychological testing to assess the brain function of individuals with neurological impairments.

Precautions

Intelligence testing requires a clinically trained examiner. The Wechsler scales should be administered, scored, and interpreted by a trained professional, preferably a psychologist or psychiatrist.

Description

All of the Wechsler scales are divided into six verbal and five performance subtests. The complete test takes 60-90 minutes to administer. Verbal and Performance IQs are scored based on the results of the testing, and then a composite Full Scale IQ score is computed. Although earlier editions of some of the Wechsler Scales are still available, the latest revisions are:

Wechsler Adult Intelligence Scale-Revised (WAIS-R)

The WAIS-R, the 1981 revision of the original Wechsler Adult Intelligence Scale, is designed for adults, ages 16-74. The 11 subtests of the WAIS-R include information, digit span, vocabulary, arithmetic, comprehension, similarities, picture completion, picture arrangement, block design, object assembly, and digit symbol. An example of questions on the subtest of similarities might be: "Describe how the following pair of words are alike or the same—hamburger and pizza." A correct response would be "Both are things to eat."

Wechsler Intelligence Scale for Children, Third Edition (WISC-III)

The WISC-III subtests includes many of the same categories of subtests as the WAIS-R. In addition, there are two optional performance subtests: symbol search and mazes.

Wechsler Preschool and Primary Scale of Intelligence (WPPSI)

The WPPSI is designed for children age 4-6½ years. The test is divided into six verbal and five performance subtests. The 11 subtests are presented in the following order: information, animal house and animal house retest, vocabulary, picture completion, arithmetic, mazes, geometric design, similarities, block design, comprehension, and sentences.

The 1997 Medicare reimbursement rate for psychological and neuropsychological testing, including intelligence testing, is $58.35 an hour. Billing time typically includes test administration, scoring and interpretation, and reporting. Many insurance plans cover all or a portion of diagnostic psychological testing.

Normal results

The Wechsler Intelligence Scales are standardized tests, meaning that as part of the test design, they were administered to a large representative sample of the target population, and norms were

KEY TERMS

Norms—Normative or mean score for a particular age group.

Representative sample—A random sample of people that adequately represents the test-taking population in age, gender, race, and socioeconomic standing.

Standard deviation—A measure of the distribution of scores around the average (mean). In a normal distribution, two standard deviations above and below the mean includes about 95% of all samples.

Standardization—The process of determining established norms and procedures for a test to act as a standard reference point for future test results.

determined from the results. The scales have a mean, or average, standard score of 100 and a standard deviation of 15. The standard deviation indicates how far above or below the norm the subject's score is. For example, a 10-year-old is assessed with the WISC-III scale and achieves a full-scale IQ score of 85. The mean score of 100 is the average level at which all 10-year-olds in the representative sample performed. This child's score would be one standard deviation below that norm.

While the full-scale IQ scores provide a reference point for evaluation, they are only an average of a variety of skill areas. A trained psychologist will evaluate and interpret an individual's performance on the scale's subtests to discover their strengths and weaknesses and offer recommendations based upon these findings.

Paula Anne Ford-Martin

Wegener's granulomatosis

Definition

Wegener's granulomatosis is a very rare disease that affects many different organs and systems of the body. It mainly attacks the respiratory system (sinuses, nose, windpipe, and the lungs) and the kidneys. One of the main features of the disease is an inflammation of the blood vessels (**vasculitis**). The inflammation narrows the blood vessels and reduces the blood flow to the affected organs. This destroys tissues and damages vital organs.

Description

Wegener's granulomatosis (WG) is not a contagious disease, and there is no evidence to suggest that it is hereditary either. It is a very rare disease, affecting only 1 in every 30,000-50,000 people. About 500 new cases are diagnosed each year. The disease can occur at any age, however, it mostly affects individuals in their 30s and 40s. It affects males and females equally. Ninety-seven percent of all patients are Caucasian, 2% are black, and 1% are of another race.

Causes and symptoms

No viral, bacterial, or other causative agent has yet been identified for WG. It is thought to be an autoimmune disease, meaning that the body's immune system attacks itself—that is, the body's own tissues.

Whenever there is an infection in the body, proteins called antibodies, which are capable of attacking the infectious agent, are formed in the blood. In WG, the antibodies that are formed are directed against the white blood cells of the immune system. They are therefore called "auto-antibodies" (antibodies against one's own body cells). These auto-antibodies bind to the blood cells and forms clumps known as immune complexes. The complexes accumulate in the tissues and the blood vessels, leading to a tumor-like (granulomatous) inflammation of the blood vessels. This slows down the blood flow to the different organs and tissues, causing damage and resulting in the many symptoms of WG.

The symptoms of WG, and the severity of the symptoms, vary from patient to patient. One of the most common features is a chronic runny nose and other cold-like symptoms that do not respond to standard treatment. The cold symptoms gradually worsen and could lead to **sinusitis** (inflammation of the sinuses), middle ear infection (**otitis media**), **cough**, coughing of blood, and inflammation of the lung (pleuritis and **pneumonia**). Other symptoms include **fever**, **fatigue**, loss of appetite, weight loss, joint **pain**, night sweats, change in urine color, and weakness.

Kidney (renal) disease is the most serious development of WG. Patients who do not have renal disease are said to have "Limited Wegener's."

Diagnosis

Early diagnosis is critical for the most effective treatment of the disease. However, there are no specific laboratory tests for WG. Blood tests are used to rule out other causes of the symptoms and to determine which organs are affected. The blood tests often show anemia (low red cell count) and high white blood cell counts. If the kidneys are involved, red blood cells are seen in the urine when viewed under a microscope. Also, blood tests aimed at measuring kidney function may show abnormalities.

Chest x rays are used to determine if the lungs are involved. **Computed tomography scans** (CT scans) of

sinuses and lungs, and **kidney biopsy**, are also important tools used in diagnosing WG.

A specific type of antibody called anti-neutrophil cytoplasmic antibody (ANCA) is seen in the blood of about 90% of the patients with WG. The ANCA is a group of antibodies directed against the individual's own white blood cells (namely, the neutrophils). These anti-neutrophil cytoplasmic antibodies are also found in other inflammatory conditions and diseases (such as HIV infection). Although the ANCA test is useful, it cannot be used by itself to make a diagnosis of WG. However, the amount of ANCA in the blood can be measured and correlates well with the progression of the disease. When there is a relapse or a flare-up, the ANCA levels go up. Levels decrease when the disease is controlled by appropriate treatment.

Since there are no definitive laboratory tests for WG, and the initial symptoms of the disease are not very specific, it takes 5-15 months, on average, to make a diagnosis of WG.

Treatment

Cyclophosphamide (Cytoxan) which is an anti-cancer drug, and **corticosteroids**, such as prednisone, are used to treat WG. These are powerful drugs that suppress the immune system. However, they are also very toxic and can have serious side effects. The patient has to be watched carefully by the doctors, and the dosage of the drugs has to be adjusted, if needed.

Since the patient's immune system is suppressed while on these drugs, he or she is at an increased risk for contracting infections. Vaccinations for flu and pneumonia are recommended.

Prognosis

In the past, approximately 80% of the patients with untreated WG died within a year of contracting the disease and 90% died within two years. Today, however, the prognosis has been dramatically improved. With appropriate treatment, patients can survive for much longer periods and lead relatively normal lives.

Approximately 50% of the patients with WG will have a relapse of the disease. This generally happens within two years of stopping the medication, but can occur at any point either during treatment or after stopping treatment. Therefore, it is extremely important that patients continue to see their doctors regularly even after stopping the medications.

KEY TERMS

Auto-antibodies—An antibody that is produced in, and reacts with, an antigen in the same person or animal.

Autoimmune disease—Any disease which causes tissue injury due to an immunological reaction of antibodies against the patient's own tissues.

Granulomatous—Resembling a tumor made of granular material.

Immune complexes—Clusters or aggregates of antigen and antibody bound together.

Vasculitis—Inflammation of the walls of the blood vessels.

Prevention

At present, there are no preventive measures known for Wegener's granulomatosis.

Weight loss drugs

Definition

Weight loss drugs are medications that may help an obese person lose weight in combination with a low-calorie diet and physical activity.

Purpose

More than 60% of adults in the United States are overweight or obese. Since the 1980s the number of overweight people has increased steadily and the number of obese people has almost doubled. Excess weight and physical inactivity account for more than 300,000 premature deaths in the United States each year, second only to smoking-related deaths.

Risks from obesity

Overweight and obese people are at higher risk for developing the following problems:

- sleep apnea (interrupted breathing while asleep)
- osteoarthritis (wearing away of the joints)
- high blood pressure
- heart disease
- stroke
- diabetes
- gallbladder disease
- gout (joint pain caused by excess uric acid)
- many common types of cancer

Body mass index (BMI)

An overweight person has an excess of body weight but not necessarily an excess of body fat. **Obesity** refers to an excessively high proportion of body fat. The BMI is used to determine whether a person is overweight or obese. It defines body weight relative to height and, for most adults, correlates with total body fat.

BMI charts are widely available; however, an approximate BMI can be calculated by the following steps:

- multiplying body weight in pounds by 703
- dividing the result by height in inches
- dividing the result by height in inches again

With the exception of very muscular people, BMI is a measure of health:

- 18.5–24.9: healthy
- 25–29.9: overweight
- 30 or above: obese

Generally the higher the BMI the higher the risk of health problems; however, excess abdominal fat is a separate health risk. Men with waists of more than 40 in (102 cm) and women with waists of more than 35 in (89 cm) are at greater risk for health problems.

Prescription weight loss drugs are approved for use only by people with BMIs of 30 or above or those with BMIs of 27 and above who have other risk factors, including the following:

- high blood pressure
- type 2 diabetes
- dyslipidemia (abnormal amounts of fat in the blood)
- sleep apnea

Even short-term weight loss in some obese people has been found to reduce the following:

- blood pressure
- blood cholesterol
- triglycerides (fats)
- insulin resistance (the inability to utilize blood sugar)

Overweight or obese patients who have not lost an average of 1 lb. (0.5 kg) per week after at least six months on a balanced low-calorie diet, including increased **exercise** and behavior therapy, may be considered candidates for weight loss drugs.

Description

Weight loss medications are prescribed only as a component of a weight loss program that includes a healthy low-calorie diet and regular physical activity. On average, people on prescription weight loss drugs lose about 5–10% of their original weight. They may lose in the range of 4.4–22 lbs. (2–10 kg) above what they might have lost following a diet and exercise program alone. Patients who lose weight initially on a drug tend to continue to respond. However, those who fail to lose 4 lbs. (2 kg) within the first month on a weight loss medication may be less likely to respond to that particular drug even at an increased dosage. Most over-the-counter weight loss drugs have been found to be ineffective, unsafe, or both. However, in 2007 the U.S. Food and Drug Administration (FDA) approved the drug Alli, a reduced-strength version of the prescription drug Xenical (orlistat), for over-the-counter sale. It is meant to be used in conjunction with a low-fat, low-calorie diet and a regular exercise program. A one-month supply of the drug costs about $60. It can help people lose 50% more weight than by dieting alone, according to its manufacturer, GlaxoSmithKline.

Most weight loss occurs within the first six months of drug use, after which the weight levels off or increases. The majority of patients regain the lost weight after discontinuing the medication. Thus short-term use of weight loss drugs may not be beneficial. However, long-term use of weight loss drugs may help maintain the lower weight. Since obesity is a chronic disorder, treatment must be continued for years or for life. However, as of 2007, sibutramine (Meridia) and orlistat (Xenical) were the only prescription weight loss drugs approved by the FDA for use for more than 12 weeks. Adipex-P (phentermine) and Tenuate (diethylpropion) are FDA-approved for short-term use.

Appetite suppressants (anorexiants)

Most FDA-approved weight loss drugs suppress the appetite by affecting one or more neurotransmitters

in the brain that control appetite and mood. Various appetite suppressants increase the secretion of dopamine, norepinephrine, or serotonin or inhibit the reuptake of these neurotransmitters into the nerve cell. Some drugs affect more than one neurotransmitter. These drugs may cause a person to feel less hungry or more satiated.

SIBUTRAMINE. Sibutramine was approved by the FDA in 1997 for long-term use. It reduces appetite by inhibiting the reuptake of norepinephrine, dopamine, and serotonin. One study found that patients taking sibutramine lost an average of 7–10 lbs. (3—5 kg) more over one year than those on a low-calorie diet alone.

AMPHETAMINES OR SYMPATHIMIMETIC DRUGS. Some amphetamines are FDA-approved for very short-term weight loss. Although most of these drugs do not cause weight loss over more than a few months, phentermine continues to be one of the two most commonly prescribed weight loss medications—along with subitramine—in the United States.

Some amphetamine-type weight loss drugs, including **methamphetamine** (Desoxyn), were approved by the FDA in the mid-1990s based on very little data. Other FDA-approved weight loss drugs for short-term use include:

- benzphetamine (Didrex)
- diethylpropion (Tenuate, Tenuate Dospan, Tepanil Ten-Tab), approved in 1959
- mazindol (Mazanor, Sanorex)
- phendimetrazine (Adipost, Bontril PDM, Bontril Slow-Release, Melfiat, Obezine, Phendiet, Phendiet-105, PT 105, Plegine, Prelu-2, X-Trozine), approved in 1982
- phentermine (Adipex-P, Fastin, Ionamin, Obenix, Oby-trim, Phentercot, Phentride, Pro-Fast, Teramine, Zantryl), approved in 1959

Lipase inhibitors

In 1999 the FDA approved orlistat (the first of a new class of anti-obesity drugs called lipase inhibitors) for long-term use. Orlistat inhibits the pancreatic enzyme lipase that breaks down dietary fat, which in turn decreases the body's absorption of dietary fat by as much as 30%. The undigested fat is excreted in the stool.

Orlistat is prescribed for overweight or obese patients who also have high cholesterol, diabetes, high blood pressure, or heart disease

Off-label use

Physicians sometimes prescribe drugs for weight loss that are not FDA-approved for that purpose—so-called off-label use. The use of weight loss medications—other than sibutramine and orlistat—for more than a 12 weeks is also considered off-label use.

Off-label weight loss drugs include:

- antidepressants, such as bupropion
- the anticonvulsant drugs topiramate and zonisamide
- the diabetes medications metformin, exenatide, and pramlintide

Antidepressants may result in moderate weight loss for up to six months after which the weight usually is regained. Metformin appears to reduce hunger and food intake and may promote small weight loss in the obese and those with type 2 diabetes.

Drugs withdrawn from the market

Although effective for long-term weight loss, fenfluramine (Pondimin and others), dexfenfluramine (Redux), and a fenfluramine/phentermine combination (fen/phen) were withdrawn from the market in 1997 after it was found that they caused potentially fatal complications.

In February of 2004 the FDA prohibited the sale of dietary supplements containing ephedrine alkaloids, including ephedra, Ma huang, Sida cordifolia, and pinellia, because of potential complications. These supplements were aggressively marketed for weight control, as well as for energy and sports performance. Although they may affect modest short-term weight loss, these drugs raise blood pressure, stress the circulatory system, and have been linked to **heart attack** and **stroke**.

Phenylpropanol amine, a drug mainly used to treat colds and **allergies**, was also taken off the market because young women who were taking it for weight loss had a higher rate of stroke due to bleeding in the brain.

Recommended dosage

Dosages of appetite suppressants vary with the individual and a full dose may be more than necessary for some people. A low dose of subitramine often is prescribed for at least the first four weeks. Once-a-day appetite suppressors should be taken 10–14 hours before bedtime. When taking more than one dose per day, the last dose should be 4–6 hours before bedtime. Long-acting capsules or tablets should be swallowed

whole, rather then chewed or cut up. Missed doses should be skipped.

The average doses of appetite suppressants are:

- sibutramin: a 10-mg capsule once a day, usually in the morning; a maximum of 15 mg per day
- benzphetamine: 25 to 50-mg tablets once a day in mid-morning or mid-afternoon
- diethylpropion: 25-mg tablets, three times per day, one hour before meals; 75-mg extended-release tablet, once a day in mid-morning
- mazindol: 1-mg tablet once a day, taken with food
- phendimetrazine: 17.5–35-mg tablets, two to three times per day, one hour before meals; 105-mg extended-release capsules, 30 to 60 minutes before the morning meal
- phentermine: 15–37.5-mg capsule or tablet, once a day, before breakfast or one to two hours after or smaller doses 30 minutes before meals; 15–30-mg oral resin capsule, once-per-day, before breakfast

The usual dose of prescription orlistat is a 120-mg capsule taken three times a day, up to one hour after each main meal that contains fat. The meal should contain no more than 30% calories from fat. Orlistat should not be taken if a meal is missed, the meal does not contain fat, or it is more than one hour past the meal. The usual dose of Alli, a reduced-strength form of orlistat, is 75 mg.

Precautions

With the exception of orlistat, all prescription weight loss medications are controlled substances. Very few studies have evaluated for their safety or effectiveness for periods of more than six months to two years. The use of any combination of weight loss drugs is not recommended. The risks of using appetite-suppressing drugs during **pregnancy** are unknown. Orlistat is approved for use in those aged 12 and above. No other weight loss drug is approved for use in children under age 16.

After beginning a weight loss drug, patients should return for follow-ups in two to four weeks, monthly for three months, and then every three months for the first year to monitor weight, blood pressure, pulse, and side effects, and have laboratory testing.

Appetite suppressants

Appetite suppressants should not be taken within 14 days of taking a monoamine oxidase (MAO) inhibitor; extremely high blood pressure and seizures may develop suddenly. Taking subitramine along with a drug that has MAO-inhibitor activity can cause a life-threatening condition called serotonin syndrome.

Sibutramine should not be used by people with the following problems:

- poorly-controlled high blood pressure
- irregular heartbeat (arrhythmia)
- a history of stroke
- heart disease
- congestive heart failure

Most appetite suppressants can be habit-forming. In late 2004 Meridia was singled out by critics as a drug that is only minimally effective and has been associated with several deaths.

Amphetamine-type weight loss drugs should not be use by anyone with the following problems:

- high blood pressure
- heart disease
- an overactive thyroid gland
- glaucoma

Amphetamine-type weight loss drugs can test positive on urine screenings for amphetamines. These drugs have a high potential for **abuse** and **addiction**.

Orlistat

Orlistat may decrease the absorption of fat-soluble **vitamins** and beta-carotene. Therefore, a daily multivitamin supplement, including vitamins A, E, K and beta-carotene, should be taken at least two hours before or after orlistat or at bedtime. Foods containing more than 30% fat should be avoided while a person is using orlistat. Gallbladder problems may become worse with orlistat.

Other precautions

Various conditions may affect the choice of a weight loss drug, including the following:

- pregnancy or breastfeeding
- a history of drug or alcohol abuse or dependence
- a history of eating disorders
- a history of depression or manic-depressive disorder
- a family history of mental illness
- the use of MAO inhibitors or other antidepressants
- migraine headaches requiring medication
- glaucoma
- diabetes mellitus
- epilepsy
- thyroid disease
- kidney problems

- gallstones
- liver disease
- problems absorbing food (malabsorption syndrome)
- high blood pressure
- heart disease, a heart condition such as arrhythmia, blood vessel disease
- future surgery that will require general anesthesia

Some dietary supplements are marketed as weight loss products. They are not reviewed by the FDA and are not necessarily safe. They may interact with other drugs and may be dangerous for people with certain medical conditions. Herbal medications have unpredictable amounts of active ingredients and unpredictable and potentially harmful side effects.

Side effects

Many overweight people are generally healthy, and the side effects of weight loss drugs may far outweigh the benefits. Side effects may be reduced by starting at the lowest effective dose, although any drug can cause an allergic reaction in any individual.

Appetite suppressants

Side effects of sibutramine and other appetite suppressants may include:

- increased blood pressure
- dry mouth
- headache
- abdominal cramps or pain
- constipation
- nausea or vomiting
- drowsiness
- insomnia
- irritability
- anxiety
- dizziness, lightheadedness, confusion
- poor coordination

Dry mouth can be relieved with sugarless candy or gum, ice, or a saliva substitute. However, dry mouth lasting more than two weeks can increase the risk of serious dental disease.

Less common side effects of appetite suppressants include:

- fast or irregular heart beat
- skin rash or hives
- fever
- sore throat
- sweating
- uncontrollable trembling or shaking
- diarrhea
- unusual bruising or bleeding
- depression

Although sibutramine side effects usually are mild and may improve with continued use, additional side effects may include:

- increased thirst
- changes in sense of taste
- heartburn
- stuffy or runny nose
- skin burning, itching, prickling, or tingling
- back pain
- painful menstruation
- weakness
- swelling in various parts of the body

Fast heart rate can be a symptom of sibutramine overdose. Other rare serious complications from subitramine include:

- chest pain
- difficulty speaking, swallowing, or breathing
- muscle stiffness
- uncoordinated or abnormal movement
- fainting
- rapid mood shifts
- enlarged pupils, eye pain, vision changes
- confusion
- seizures

Other side effects of amphetamines can include:

- a false sense of well-being
- an unpleasant taste
- decreased alertness
- restlessness
- uncontrollable activity or excitement
- hallucinations
- increased need to urinate
- difficult or painful urination
- numbness, particularly on one side of the face or body
- blurred vision
- changes in libido or decreased sexual function

Higher dosages, more frequent doses, or longer-term use of amphetamines can lead to physical dependence or overdose, with symptoms that include:

- skin disease
- severe insomnia

KEY TERMS

Amphetamines—Sympathomimetic amines; sometimes called speed; synthetic chemicals that stimulate the central nervous system.

Body mass index (BMI)—The correlation of body weight with height; usually correlates with total body fat.

Dopamine—A neurotransmitter and precursor of norepinephrine; found in high concentrations in the brain.

Ephedrine—A sympathomimetic amine from plants of the genus *Ephedra* or chemically synthesized; an asthma medication that previously was used in weight loss drugs.

Lipase—A fat-splitting enzyme found in pancreatic juice, blood, and many tissues.

Neurotransmitter—A substance that helps transmit impulses between two nerve cells or a nerve and muscle.

Norepinephrine—A hormone that constricts blood vessels.

Orlistat—A drug that inhibits lipase.

Phentermine—An amphetamine prescribed for appetite suppression.

Serotonin—5-Hydroxytryptamine; a chemical in various parts of the body that stimulates smooth muscle contraction, constricts blood vessels, and inhibits stomach secretions.

Sibutramine—An appetite-suppressing drug that may increase the activity of norepinephrine and serotonin in the brain.

- excessive excitability or irritability
- panic
- violent urges
- personality changes
- severe mental illness
- high or low blood pressure
- seizures
- coma

Symptoms of withdrawal may be lessened or prevented by gradually reducing the dosage.

Orlistat

Orlistat side effects usually are mild and can improve with continued use. They may include the following:

- intestinal discomfort or cramping
- flatulence
- frequent, urgent need to defecate
- inability to control bowel movements and leakage
- oily diarrhea
- flu- or cold-like symptoms
- irregular menstrual periods

Less common side effects of orlistat include:

- rectal pain
- back pain
- tooth or gum problems
- chest tightness
- wheezing
- anxiety

Orlistat side effects requiring immediate medical attention include:

- itching, rash, or hives
- fever
- frequent, difficult, or painful urination
- bloody or cloudy urine
- swelling of body parts
- chest pain
- difficulty breathing
- earache or hearing changes

Orlistat side effects can be worsened by eating meals with at least 30% of total calories from fat. Side effects usually disappear within two to three days after discontinuing the drug.

Interactions

Appetite-suppressants can interact negatively with numerous other drugs, including the following:

- other appetite suppressants and amphetamines
- caffeine
- cold and allergy medicines
- asthma medications
- selective serotonin reuptake inhibitors (Saris)
- tricycles antidepressants
- medications used during surgical, dental, or emergency procedures
- cocaine and other street drugs

In addition to the above, subitramine is known to interact with numerous other drugs, including the following:

- pain relievers and muscle relaxants
- sulfa antibiotics
- antifungal medications
- sedatives, sleeping pills, tranquilizers
- high-blood-pressure medications
- migraine-headache medications
- medications for nausea, anxiety, mental illness, seizures
- blood thinners, such as warfarin (Coumadin)
- chemotherapies

Orlistat may interact with the following:

- other weight loss medications
- diabetes medications, including insulin
- blood thinners
- herbal products
- cyclosporine

West Nile virus

Definition

West Nile virus is a mosquito-borne virus that causes viral illnesses of varying seriousness, ranging from no symptoms or mild flu-like symptoms to **encephalitis** or **meningitis**.

Description

The primary hosts of West Nile virus (WNV) are birds, in which the virus numbers multiply before being transmitted by mosquitoes to the next victim. Over 140 species of birds can be infected with WNV. Besides birds, the virus can infect other vertebrates, including humans. WNV is a flavivirus that belongs to the **Japanese encephalitis** serocomplex, which includes St. Louis encephalitis, Murray Valley encephalitis, and Kunjin virus. Infections occur generally between late summer and early fall in temperate areas, and throughout the year in southern climates. Although typical manifestation of WNV is asymptomatical, the virus can cross the blood-brain barrier and cause severe illness and **paralysis**.

WNV was originally isolated in a feverish woman living in the West Nile District of Uganda during 1937. The virus was ecologically characterized in Egypt during the 1950s and later linked to severe human meningoencephalitis in elderly patients during a 1957 outbreak in Israel. Since 1937, subsequent outbreaks of WNV have been reported in Africa, Asia, Australia, Oceania, Western Europe, and the Middle East.

In the summer of 1999, WNV was first reported in the New York City area and then spread rapidly across the entire continent. It is still unknown how the WNV reached the United States, but it is suspected that the transport of infected birds or the international

(Table by PreMediaGlobal. Reproduced by permission of Gale, a part of Cengage Learning.)

travel of infected humans may have been to blame. After its arrival in the New Work area, the virus spread rapidly across the United States, as well as north into Canada and south into Mexico. In 2002, a severe outbreak of WNV in the United States killed 284 people and caused 2,944 cases of severe brain damage. As of January 2005 the Center for Disease Control (CDC) has recorded avian or animal WNV infections in every state except Alaska, Hawaii, and Washington.

Life Cycle and Transmission

Like most flaviviruses, the WNV is maintained in a natural host-vector-host cycle, where the primary vector is the mosquito. The zoonotic cycle begins with a reservoir host, which is most commonly of avian origin. When a mosquito feeds on the infected bird, the virus is passed to the insect along with the blood meal. The virus then multiplies rapidly within the mosquito's body and salivary glands over the next few days. When the insect feeds on another animal or human, the virus can be transmitted through the bite and cause serious illness.

Most mosquitoes can become infected with the WNV. However, female mosquitoes of the *Culex pipiens* species are of particular concern, as they live in suburban and urban areas, can survive through the winter, prefer to feed on birds, and frequently bite humans. The *Culex pipiens*, also known as the house mosquito, is also the most common vector for WNV transmission. *Culex restuan*, *Culex quinquefasciatus*, *Aedes Albopictus*, and *Aedes Vexans* are also common carriers of the WNV.

Common food sources for mosquitoes, birds represent the primary WNV reservoir species. A continent-wide study published in 2007 suggests that WNV has severely affected bird populations associated with human habitats in North America, showing that WNV is indeed the main factor behind the observed large-scale declines in bird populations. For instance, in 2005, crow populations declined regionally by up to 45% from 1998 levels, although they had increased steadily for two decades. Crow declines have been positively correlated with the intensity of human WNV epidemics within each region studied. Similar correlations between human infections and impacts on bird species were strongest for house wrens and eastern bluebirds. The virus has also been identified in more than 250 bird species in the United States, including blue jays, ravens, magpies, sparrows, and starlings. Many in the scientific community believe that the rapid spread of WNV in North America may be due in part to the migratory nature of birds. Infected birds carry the virus with them as they travel in summer and winter, thus acting as reservoirs in their new nesting sites.

Most vertebrates, such as alligators, bats, chipmunks, skunks, squirrels, and rabbits, can also be infected with WNV. Horses, in particular, are commonly infected with WNV. Like humans, the majority of horses suffer either no or mild symptoms, but severe illness and **death** can and does occur. There are relatively few cases of dogs and cats becoming infected

with WNV. Animals of all species exhibiting **fever**, weakness, poor coordination, spasms, seizures, and/or personality changes may be infected with WNV.

There is no evidence of WNV transmission from person–to–person through touch, kissing, or other contact. However, there is evidence of WNV transplacental (mother-to-child) transmission, as well as viral transmission through **breastfeeding**. As such, pregnant mothers should be aware of the presence of WNV in their area and take appropriate precautions. The transmission of WNV has also been evidenced in blood–transfusions and organ transplants although the current blood supply is now tested for the presence of the WNV. People that are immunocompromised (from disease or **chemotherapy**, for example) and people aged 50 and older represent the highest risk group for serious WNV infection.

Demographics

In the United States, the CDC monitors and records human WNV infections. In 2007, 3,404 cases were reported, including 98 fatalities in every state except Alaska, Hawaii, New Hampshire, Vermont, Washington, and West Virginia. In 2007, 14 cases were reported in eastern Canada, 1,976 cases were reported in central Canada, and 336 cases were reported in western Canada. Experts believe that WNV is now firmly established in the Western Hemisphere.

Among those with severe illness due to West Nile virus, fatality rates range from 3% to 15% and are highest among the elderly. Less than 1% of people who become infected with West Nile virus will develop severe illness as most people who get infected do not develop any disease at all.

Causes and symptoms

The exact mechanism of WNV–caused illnesses remains unclear. However, it is suspected that the virus enters the host's blood stream and multiples. It can then develop to the point where it crosses the blood-brain barrier, which separates the blood from the central nervous system. When this occurs, the virus can infect the brain, spinal cord, and other vital systems, creating a potentially deadly inflammatory response.

The incubation period for WNV after infection typical ranges between 3 to 14 days. Eighty percent of infected persons will exhibit no clinically apparent symptoms whatsoever. Roughly 20% of infected persons will exhibit a series of mild flu-like symptoms, also known as West Nile Fever. These mild symptoms can persist for 3 to 6 days, possibly weeks, and include:

- eye pain
- fever
- headache
- loss of appetite
- lymphadenopathy (abnormal enlargement of the lymph nodes)
- malaise (nonspecific bodily discomfort)
- myalgia (nonspecific muscular pain/tenderness)
- nausea
- rash (on the neck, torso, and limbs)
- vomiting

In rare cases, approximately 1 in 150 cases (0.7%), WNV can cross the blood-brain barrier and develop into a severe neuroinvasive disease. Immunocompromised and elderly (>50 years of age) patients are at an increased risk for developing more severe syndromes; a 20-fold increase in incidence among older patients. Symptoms indicating the possible presence of severe West Nile–related syndromes include:

- severe headache
- high fever
- acute muscle weakness
- neck stiffness
- convulsions and tremors
- disorientation and stupor
- paralysis
- coma

People exposed to WNV infection, especially the immunocompromised and elderly, should contact their health provider immediately if they develop a severe **headache** accompanied by high fever.

Typically, severe WNV syndromes manifest as one of three syndromes: West Nile encephalitis (inflammation of the brain); West Nile meningitis (inflammation of the meninges of the brain and spinal cord); or West Nile meningoencephalitis (inflammation of both the brain and the meninges). These three syndromes can cause severe brain damage and even death. Severe WNV disease carries a mortality rate ranging between 3% and 15%, with elderly patients suffering the highest mortality rate. The majority of these deaths are a result of complication attributable to West Nile meningoencephalitis. Additionally, severe WNV disease can cause acute vision loss due to inflammatory disorders of the eye, such as chorioretinitis, **optic neuritis**, retinal **vasculitis**, **uveitis**, and vitritis. Less frequently, the patient can exhibit acute

flaccid paralysis, similar to poliomyelitis (**polio**) or Guillain-Barré syndrome, caused by inflammation of the spinal cord and/or damage to the peripheral nerves. In some severe cases, this acute flaccid paralysis can disrupt muscles that control breathing and result in **respiratory failure**.

Diagnosis

A proper diagnosis of WNV infection depends heavily upon clinical presentation, laboratory testing, and patient history. Patients with a known susceptibility to WNV (the elderly and immunocompromised) that exhibit symptoms during the late spring to early fall, or at any time in warmer climates, should be tested for WNV and other arboviral infections. Additionally, health providers should remain constantly aware of the local presence of WNV activity, such as reports of recent animal and/or human cases. Similarities of symptomology between and serological cross-reactivity of WNV and other flaviviruses, may lead to confusion and an incorrect diagnosis. Health providers must use thorough laboratory testing to differentiate WNV antibodies from those of other arboviruses.

Symptomatic WNV infection can be classified as either non–neuroinvasive or neuroinvasive, with each being identified according to certain criteria.

Non–neuroinvasive

The majority of WNV infections are asymptomatic. In approximately 20% of WNV cases, clinically recognizable symptoms can manifest. However, to be clinically classified as non-neuroinvasive West Nile disease, the following must be true:

- no neuroinvasive symptomology
- presence of fever without other recognizable cause
- four–fold or greater increase in serum antibody titer
- virus isolated from and or deomonstrated in blood, tissue, cerebrospinal fluid (CSF), or other bodily fluid
- virus–specific immunoglobulin M (IgM antibodies demonstrated in CSF through antibody-capture methods

Neuroinvasive

In rare cases (0.7%) of West Nile disease, the virus crosses the blood-brain barrier and manifests in severe and life-threatening symptomology. Clinical confirmation of neuroinvasive of neuroinvasive disease requires the presence of a fever and at least one of the following:

- acutely altered mental status, such as disorientation, stupor, or coma
- acute central or peripheral neurological difficulties, such as paralysis, nerve palsy, sensory deficits, and abnormal muscle function
- an increased white blood cell concentration in the CSF coupled with symptoms of meningitis, such as severe headache and neck pain

Treatment

Currently, there are no treatment modalities for WNV infection. Instead, supportive care is utilized to treat the varying symptoms and syndromes associated with the various West Nile diseases. Although milder symptoms can be treated at home, severe symptoms can require hospitalization. Treatment of severe symptoms may require the use of intravenous infusions, airway and respiratory management and support, and use of preventive measures against secondary infection.

Clinical trials

Many clinical trials for the study and treatment of WNV are currently sponsored by the National Institutes of Health (NIH) and other agencies. In 2007, NIH reported 12 ongoing or recently completed studies, including five in the recruitment stage.

A few examples include:

- The safety of Omr–IgG–am for the treatment of WNV infection. (NCT00069316)
- The examination of how WNV affects the human body. (NCT00069303)
- The study of WNV outcomes and of the effects of the disease on individuals, specifically on their nervous systems. (NCT00138463)
- The evaluation of the safety of an experimental vaccine for preventing WNV. (NCT00300417)

Clinical trial information is constantly updated by NIH. The most recent information on WNV trials can be found at http://clinicaltrials.gov/ct2/results?term=west+nile+virus.

Prognosis

The majority of WNV infections will manifest asymptomatically. West Nile fever offers an excellent prognosis associated with quick recovery and no adverse side-effects. The majority of symptoms will resolve within a few days or weeks of manifestation.

However, the prognosis is not a positive for patients suffering the more severe syndromes attributable to WNV infection. Symptoms of West Nile encephalitis, West Nile meningitis, and West Nile

KEY TERMS

Flavivirus—An arbovirus that can cause potentially serious diseases, such as dengue, yellow fever, Japanese encaphilitis, and West Nile fever.

Guillain-Barré—A disorder in which the body's immune system attacks part of the peripheral nervous system. Weakness, tingling, and abnormal sensations in the arms and upper body can progress until the muscles become totally disabled and the patient is effectively paralyzed.

Meninges—A series of membranous layers of connective tissue that protect the central nervous system (brain and spinal cord). Damage or infection to the meninges, such as in meningitis, can cause serious neurological damage and even death.

Zoonotic diseases—Diseases caused by infectious agents that can be transmitted between (or are shared by) animals and humans. This can include transmission through the bite of an insect, such as a mosquito.

meningoencephalitis can last for several weeks, as well as cause severe and permanent neurological damage. Inflammation can interfere with the brain and central nervous system and result in death, especially among the elderly population. Patients with West Nile poliomyelitis may suffer prolonged muscle weakness and loss of motor control. Long-term **rehabilitation** is typically required and a full recovery is not assured. If the poliomyelitis affects muscles used for breathing, death from respiratory failure may result.

Prevention

Although there is a vaccine used for horses and exotic birds in zoos, there is no WNV vaccine for humans at the current time. Several pharmaceutical companies, however, have WNV vaccines in development.

Prevention techniques of WNV typically coincide with avoidance measures against mosquito **bites**, the primary source of the virus. These include the use of insect repellant (with 5% to 20% DEET) on exposed body parts, wearing loose-fitting clothes over the limbs and torso while outdoors, using mosquito coils and/or citronella candles outdoors, and limiting outdoor activities during peak biting periods and/or in areas with high mosquito density. While camping outdoors, knockdown spray or bed netting with pyrethrum is suggested. Mosquito eradication programs have been instituted in most major cities. Public health authorities can utilize United States Environmental Protection Agency-approved "adulticidies" in areas suspected of the presence of WNV.

The *Culex pipiens* mosquito is the primary vector of WNV transmission and is also commonly live and feed in urban areas. Special precautions should be taken to reduce exposure to these potentially infected insects. Screen doors and enclosed porches can help keep mosquitoes from coming into the house. It should be noted that studies have shown that mosquito control devices such as "bug zappers" and CO2-baited traps do not significantly reduce the risk of being bitten.

Removing potential mosquito breeding areas from near the home and from the neighborhood can further reduce the risk of bites. Any container which can collect half an inch of standing water can become a potential breeding site in as little as five days. Old tires, empty plant pots, and empty trashcans should be removed, while water sources like ponds or birdbaths should be cleaned regularly. Standing water on any property should be drained, such as from clogged eaves. Swimming pools and hot tubs should be properly covered and chlorinated to prevent mosquitoes breeding in them.

Wheezing

Definition

Wheezing is a high-pitched whistling sound associated with labored breathing.

Description

Wheezing occurs when a child or adult tries to breathe deeply through air passages that are narrowed or filled with mucus as a result of:

- allergy
- infection
- illness
- irritation

Wheezing is most common when exhaling. It is sometimes accompanied by a mild sensation of tightness in the chest. **Anxiety** about not being able to breathe easily can cause muscle tension that makes matters worse.

Causes and symptoms

Wheezing is the symptom most associated with **asthma**. It can be caused by:

- exposure to allergens (food, pollen, and other substances that cause a person to have an allergic reaction)
- fumes
- ice-cold drinks or very cold air
- medication
- strenuous exercise
- weather changes
- foreign objects trapped in the airway
- cystic fibrosis and other genetic disorders
- respiratory illnesses, such as pneumonia, bronchitis, congestive heart failure, and emphysema

Diagnosis

A family physician, allergist, or pulmonary specialist takes a medical history that includes questions about **allergies** or unexplained symptoms that may be the result of allergic reactions. If the pattern of the patient's symptoms suggests the presence of allergy, skin and blood tests are performed to identify the precise nature of the problem.

A pulmonary function test may be ordered to measure the amount of air moving through the patient's breathing passages. X rays are sometimes

indicated for patients whose wheezing seems to be caused by chronic **bronchitis** or **emphysema**.

In 2004, researchers in Japan discovered a new method for diagnosing asthma in infants by testing for certain antibodies in their sputum (mucus that spits up from the bronchi).

Treatment

Mild wheezing may be relieved by drinking plenty of juice, water, weak tea, and broth. Ice-cold drinks should be avoided.

A vaporizer can help clear air passages. A steam tent, created by lowering the face toward a sink filled with hot water, placing a towel over the head and sink, and inhaling the steam, can do likewise.

Bronchodilators (medications that help widen narrowed airways) may be prescribed for patients whose wheezing is the result of asthma. Newer asthma medications taken daily can help prevent asthma attacks, as can avoiding asthma and allergy triggers.

Antibiotics are generally used to cure acute bronchitis and other respiratory infections. **Expectorants** (cough-producing medications) or certain bronchodilators are prescribed to remove excess mucus from the breathing passages.

If wheezing is caused by an allergic reaction, **antihistamines** will probably be prescribed to neutralize body chemicals that react to the allergen.

Medical emergencies

Breathing problems can be life-threatening. Immediate medical attention is required whenever an individual:

- turns blue or gray and stops breathing
- becomes extremely short of breath, and is unable to speak
- coughs up bubbly-pink or white phlegm
- seems to be suffocating
- develops a fever of 101°F (38.3°C) or higher
- wheezes most of the time and coughs up gray or greenish phlegm

Alternative treatment

Certain **yoga** positions (Bridge, Cobra, Pigeon, and Sphinx) may relieve wheezing by improving breathing control and reducing **stress**. Patients whose wheezing is related to asthma, chronic bronchitis, emphysema, or a severe allergic reaction may benefit from these techniques, but must continue to have their condition monitored by a conventional physician.

Prognosis

Mild wheezing caused by infection or acute illness usually disappears when the underlying cause is eliminated.

Some doctors believe that childhood respiratory infections may activate parts of the immune system that prevent asthma from developing.

Prevention

Stopping **smoking** can eliminate wheezing. So can reducing or preventing exposure to other substances that cause the problem.

Whiplash

Definition

Whiplash is a sudden, moderate-to-severe strain affecting the bones, discs, muscles, nerves, or tendons of the neck.

Description

The neck is composed of seven small bones. Known as the cervical spine, these bones:

- support the head
- help maintain an unobstructed enclosure for the spinal cord
- influence the shape and structure of the spine
- affect posture and balance

About 1,000,000 whiplash injuries occur in the United States every year. Most are the result of motor vehicle accidents or collisions involving contact sports. When unexpected force jerks the head back,

then forward, the bones of the neck snap out of position, and irritated nerves can interfere with flow of blood and transmission of nerve impulses. Pinched nerves can damage or destroy the function of body parts whose actions they govern.

Risk factors

Osteoarthritis of the spine increases the risk of whiplash injury. So do poor driving habits, driving in bad weather, or driving when tired, tense, or under the influence of alcohol or other drugs.

Causes and symptoms

Tension shortens and tightens muscles. **Fatigue** relaxes them. Either condition increases the likelihood that whiplash will occur and the probability that the injury will be severe.

Sometimes symptoms of whiplash appear right away. Sometimes they do not develop until hours, days, or weeks after the injury occurs. Symptoms of whiplash include:

- pain or stiffness in the neck, jaw, shoulders, or arms
- dizziness
- headache
- loss of feeling in an arm or hand
- nausea and vomiting

Depression and vision problems are rare symptoms of this condition.

Diagnosis

Whiplash is difficult to diagnose because x rays and other imaging studies do not always reveal changes in bone structure. Organs affected by nerve damage or reduced blood supply may generate symptoms not clearly related to whiplash.

Diagnosis is based on observation of the patient's symptoms, medical history, **physical examination**, and neurological studies to determine whether the spine has been injured.

Treatment

Medication, **physical therapy**, and supportive measures are used to treat whiplash. Chiropractors gently realign the spine to relax pinched nerves or improve blood flow. A patient whose symptoms are severe may wear a soft, padded collar (Thomas collar or cervical collar) until the **pain** diminishes.

When pressure on the root of the nerve causes loss of strength or sensation in a hand or arm, a cervical **traction** apparatus may be recommended.

Self-care

Inflammation and cramping can be alleviated by wrapping ice or an ice pack in a thin towel and applying it to the injured area for 10-20 minutes every hour. After the first 24 hours, painful **muscle spasms** can be prevented by alternating cold packs with **heat treatments**. Letting a warm shower run on the neck and shoulders for 10-20 minutes twice a day is recommended. Between showers, warm towels or a heat lamp should be used to warm and soothe the neck for 10-15 minutes several times a day.

Improving posture is important, and gentle massage can be beneficial. Sleeping without a pillow promotes healing, and a cervical collar or small rolled towel pinned under the chin can provide support and prevent muscle fatigue.

Alcohol should be avoided. A chiropractor, primary care physician, or orthopedic specialist should be notified whenever a painful neck injury occurs. Another situation requiring attention is if the face or arm weaken or become painful or numb following a neck injury.

Prognosis

With treatment, whiplash can usually be cured in one week to three months after injury occurs. If nerve roots are damaged, **numbness** and weakness may last until recovery is complete.

Prevention

Chiropractors can recommend diet and **exercise** techniques to reduce **stress** and tension. Careful, defensive driving, wearing seatbelts, and using padded automobile headrests can lessen the likelihood of whiplash.

Whipple's disease *see* **Malabsorption syndrome**

KEY TERMS

Band—Immature neutrophil.

Basophil—White blood cell that increases in response to parasitic infections and allergic reactions.

Differential—Blood test that determines the percentage of each type of white blood cell in a person's blood.

Eosinophil—White blood cell that increases in response to parasitic infections and allergic reactions.

Leukocytosis—A white count increased to over 10,000/µL.

Leukopenia—A white count decreased to less than 4,000/µL.

Lymphocyte—White blood cell that fights viral and some bacterial infections by direct attack or the production of antibodies.

Monocyte—White blood cell that increases during a variety of conditions including severe infections. It removes debris and microorganisms by phagocytosis.

Neutrophil—White blood cell that increases in response to bacterial infection. It removes and kills bacteria through phagocytosis.

Phagocytosis—A process by which a white blood cell envelopes and digests debris and microorganisms to remove them from the blood.

White blood cell count and differential

Definition

The white blood cell count and differential determine the number of white blood cells and the percentage of each type of white blood cell in a person's blood. These tests are included in general health examinations and help investigate a variety of illnesses, including infection, allergy, and leukemia.

Purpose

The white blood cell count provides a clue to the presence of illness. White cells protect the body by fighting infection and attacking foreign material. When extra white cells are needed, the bone marrow increases production.

There are five types of white cells, each with different functions: neutrophils, lymphocytes, monocytes, eosinophils, and basophils. The differential reveals if these cells are present in a normal distribution or if one cell type is increased or decreased. This information helps diagnose specific types of illness.

Conditions or medications that weaken the immune system, such as **AIDS** or **chemotherapy**, cause a decrease in white cells. The white cell count detects dangerously low numbers of white cells.

Recovery from illness can be monitored by the white cell count. Counts continuing to rise or fall to abnormal levels indicate a worsening condition; counts returning to normal indicate improvement.

Description

Neutrophils increase in response to bacterial infection. They destroy bacteria by enveloping and digesting them, a process called phagocytosis. When many neutrophils are needed, they are released from the bone marrow as immature cells, called bands or stab cells.

Lymphocytes fight viral infections and some bacterial infections. Certain lymphocytes directly attack invading microorganisms; others produce antibodies that attack and destroy microorganisms and other foreign material. Large lymphocytes, called atypical lymphocytes, are seen during **infectious mononucleosis** and other illnesses.

Monocytes increase during severe infections, and other conditions. They remove debris and microorganisms by phagocytosis. Eosinophils and basophils increase in response to allergic reactions and parasitic infection.

White cell counts are usually done on an automated instrument. A sample of blood is mixed with a chemical to burst the red blood cells. The remaining white cells are counted by the instrument.

The differential is done by spreading a drop of blood on a microscope slide. The slide is stained with a special stain and examined under a microscope. One hundred white cells are counted and identified as either neutrophils, bands, lymphocytes, monocytes, eosinophils or basophils. Any atypical or immature cells also are counted. Cells are identified by the shape and appearance of the nucleus, the color of cytoplasm (the background of the cell), and the

presence and color of granules. The percentage of each cell type is reported. At the same time, red cells and platelets are examined for abnormalities in appearance. Some instruments perform an automated differential.

Both the white blood cell count (also called white count or leukocyte count) and the differential (also called diff) are covered by insurance. Results are available the same day.

Preparation

This test requires 7 mL of blood. A healthcare worker ties a tourniquet on the person's upper arm, locates a vein in the inner elbow region, and inserts a needle into that vein. Vacuum action draws the blood through the needle into an attached tube. Collection of the sample takes only a few minutes.

Aftercare

Discomfort or bruising may occur at the puncture site. Pressure to the puncture site until the bleeding stops reduces bruising; warm packs relieve discomfort. The person may feel dizzy or faint.

Normal results

Total white cell count 5,000-10,000 uL. Neutrophils 50-60%. Lymphocytes 20-40%. Monocytes 2-6%. Eosinophils 1-4%. Basophils 0.5-1%. Bands 0-3%.

Abnormal results

The white cell count and differential are interpreted according to a person's clinical condition and medical history. **Leukocytosis** (a white count increased to over 10,000/uL) is seen in bacterial infections, inflammation, leukemia, trauma, and **stress**. Leukopenia (a white count decreased to less than 4,000/μL) is seen in some viral infections or severe bacterial infections and in conditions that affect the bone marrow, such as dietary deficiencies, chemotherapy, **radiation therapy**, and autoimmune diseases.

Whooping cough

Definition

Whooping **cough**, also known as pertussis, is a highly contagious disease that causes classic spasms (paroxysms) of uncontrollable coughing, followed by a sharp, high-pitched intake of air that creates the characteristic "whoop" of the disease's name.

Demographics

The number of cases of whooping cough in the United States has periodically increased with a peak every 2-5 years since the 1980s. Cases occur equally in males and females. Whites make up the large majority at over 85% of cases diagnosed. People under the age of 20 years make up over 75% of cases, most of these being reported in children under the age of one or between the ages of 10 and 19. Because the whooping cough **vaccination** does not provide lifelong immunity and immunity is no longer evident after 12 years, people must be revaccinated in order to be protected.

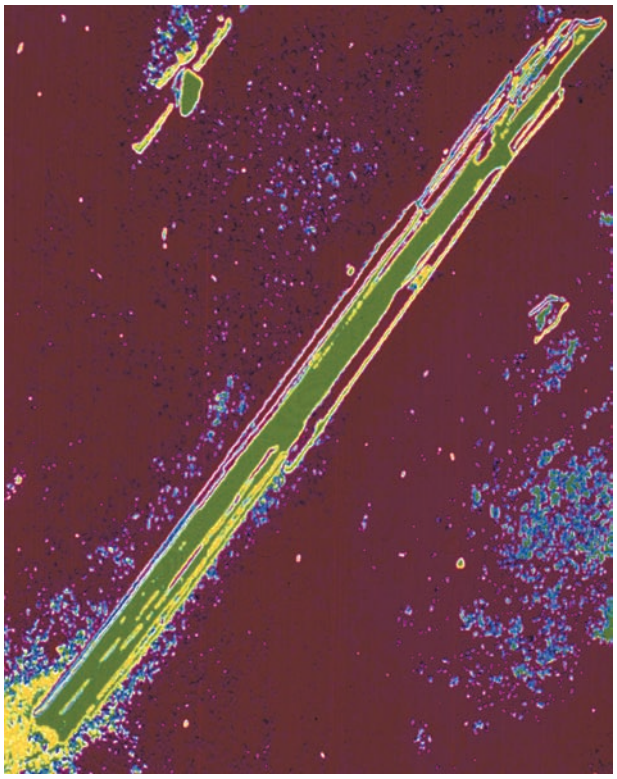
Description

Whooping cough is caused by a bacteria called *Bordatella pertussis*. *B. pertussis* causes its most severe symptoms by attaching itself to cells in the respiratory tract that have cilia. Cilia are small, hair-like projections that beat continuously, and serve to constantly sweep the respiratory tract clean of such debris as mucus, bacteria, viruses, and dead cells. When *B. pertussis* interferes with this normal janitorial function, mucus and cellular debris accumulate and cause constant irritation to the respiratory tract, triggering coughing and increasing further mucus production.

Whooping cough is a disease that exists throughout the world. While people of any age can contract whooping cough, children under the age of two are at the highest risk for both the disease and for serious complications and **death**. Apparently, exposure to *B. pertussis* bacteria earlier in life gives a person some immunity against infection with it later on. Subsequent infections resemble the **common cold**.

Causes and symptoms

Whooping cough has four somewhat overlapping stages: incubation, catarrhal stage, paroxysmal stage, and convalescent stage.



A magnified image of a pertussis toxin crystal that causes whooping cough. *(Custom Medical Stock Photo, Inc. Reproduced by permission.)*

An individual usually acquires *B. pertussis* by inhaling droplets infected with the bacteria coughed into the air by someone with the infection. Incubation is the symptomless period of 7-14 days after breathing in the *B. pertussis* bacteria, and during which the bacteria multiply and penetrate the lining tissues of the entire respiratory tract.

The catarrhal stage is often mistaken for an exceedingly heavy cold. The patient has teary eyes, sneezing, **fatigue**, poor appetite, and an extremely runny nose (rhinorrhea). This stage lasts about 10–14 days.

The paroxysmal stage, lasting two to four weeks, begins with the development of the characteristic whooping cough. Spasms of uncontrollable coughing, the "whooping" sound of the sharp inspiration of air, and **vomiting** are all hallmarks of this stage. The whoop is believed to occur due to inflammation and mucous, which narrow the breathing tubes, causing the patient to struggle to get air into his or her lungs; the effort results in intense exhaustion. The paroxysms (spasms) can be induced by activity, feeding, crying, or even overhearing someone else cough.

The mucus produced during the paroxysmal stage is thicker and more difficult to clear than the more watery mucus of the catarrhal stage, and the patient becomes increasingly exhausted attempting to clear the respiratory tract through coughing. Severely ill children may have great difficulty maintaining the normal level of oxygen in their system and may appear somewhat blue (cyanotic) after a paroxysm of coughing, due to the low oxygen content of their blood. Such children may experience swelling and degeneration of the brain (encephalopathy), which is believed to be caused both by lack of oxygen to the brain during paroxysms and also by bleeding into the brain caused by increased pressure during coughing. Seizures may result from decreased oxygen to the brain. Some children have such greatly increased abdominal pressure during coughing that hernias result (hernias are the abnormal protrusion of a loop of intestine through a weak area of muscle). Another complicating factor during this phase is the development of **pneumonia** from infection with another bacterial agent; the bacteria takes hold due to the patient's already-weakened condition.

If the patient survives the paroxysmal stage, recovery occurs gradually during the convalescent stage, usually taking about three to four weeks. However, spasms of coughing may continue to occur over a period of months, especially when a patient contracts a cold, or other respiratory infection.

Diagnosis

Examination

Diagnosis based just on the patient's symptoms is not particularly accurate, as the catarrhal stage may appear to be a heavy cold, a case of **influenza**, or a simple **bronchitis**. Other viruses and **tuberculosis** infections can cause symptoms similar to those found during the paroxysmal stage. The presence of a pertussis-like cough along with an increase of certain specific white blood cells (lymphocytes) is suggestive of whooping cough. However, cough can occur from other pertussis-like viruses.

Tests

The most accurate method of diagnosis is to culture (grow on a laboratory plate) the organisms obtained from swabbing mucus out of the nasopharynx (the breathing tube continuous with the nose). *B. pertussis* can then be identified by examining the culture under a microscope.

Treatment

Drugs

Treatment with the antibiotic erythromycin is helpful only at very early stages of whooping cough,

KEY TERMS

***Bordatella pertussis*—**A bacteria that causes whooping cough by attaching itself to cells in the respiratory tract.

Cilia—Tiny, hair-like projections from a cell. In the respiratory tract, cilia beat constantly in order to move mucus and debris up and out of the respiratory tree, in order to protect the lung from infection or irritation by foreign bodies.

Encephalopathy—Swelling and degeneration of the brain.

Lymphocytes—A type of white blood cell.

Nasopharynx—The breathing tube continuous with the nose.

Rhinorrhea—A name for the common cold.

during incubation and early in the catarrhal stage. After the cilia and the cells bearing those cilia are damaged, the process cannot be reversed. Such a patient will experience the full progression of whooping cough symptoms; symptoms only improve when the old, damaged lining cells of the respiratory tract are replaced over time with new, healthy, cilia-bearing cells. However, treatment with erythromycin is still recommended to decrease the likelihood of *B. pertussis* spreading. In fact, all members of the household where a patient with whooping cough lives should be treated with erythromycin to prevent the spread of *B. pertussis* throughout the community.

Home remedies

The only other treatment is supportive and involves careful monitoring of fluids to prevent **dehydration**; rest in a quiet, dark room to decrease paroxysms; and suctioning of mucus. Patients should be hospitalized if at risk for complication, such as infants from birth to six months of age.

Prognosis

Just under 1% of all cases of whooping cough cause death. Children who die of whooping cough usually have one or more of the following three conditions present:

- severe pneumonia, perhaps with accompanying encephalopathy
- extreme weight loss, weakness, and metabolic abnormalities due to persistent vomiting during paroxysms of coughing
- other pre-existing conditions, so that the patient is already in a relatively weak, vulnerable state (such conditions may include low birth weight babies, poor nutrition, infection with the measles virus, presence of other respiratory or gastrointestinal infections or diseases)

Prevention

The mainstay of prevention lies in programs similar to the mass immunization program in the United States, which begins immunization inoculations when infants are two months old. The pertussis vaccine, most often given as one immunization together with **diphtheria** and **tetanus** (DTP or DTaP), has greatly reduced the incidence of whooping cough.

There has been some concern about serious neurologic side effects from the vaccine itself. This concern led huge numbers of parents in England, Japan, and Sweden to avoid immunizing their children, which in turn has led to major epidemics of disease in those countries. However, several carefully constructed research studies have disproved the idea that the pertussis vaccine is the cause of neurologic damage. Furthermore, a newer formulation of the pertussis vaccine is available. Unlike the old whole cell pertussis vaccine, which is composed of the entire bacterial cell that has been deactivated (and therefore unable to cause infection), the newer acellular pertussis vaccine does not use a whole cell of the bacteria. Instead, it is made up of between two and five chemical components of the *B. pertussis* bacteria. The acellular pertussis vaccine appears to greatly reduce the risk of unpleasant reactions to the vaccine, including high **fever** and discomfort following vaccination.

Wilderness medicine

Definition

Wilderness medicine encompasses the prevention, diagnosis, and treatment of injuries and medical conditions that may occur during activities in remote territories.

Purpose

Activities that may require wilderness medicine include backpacking, cross-country skiing, mountaineering, white water rafting, scuba diving, and exploration in undeveloped regions such as deserts or jungles. Wilderness medicine has evolved to deal with situations in which definitive medical care is hours or days away, and in which patients may require quick or extended attention. Wilderness medicine utilizes **first aid** techniques, but requires additional skills that take into account demanding environments, uncommon threats to health, hazardous or lengthy travel to medical facilities, and difficulties in obtaining food, water, and shelter.

Wilderness medicine uses techniques to assess and treat a variety of conditions and injuries, including:

- wounds and burns
- external and internal bleeding
- cardiac arrest
- head injuries
- spinal cord injuries
- fractures and dislocations
- altitude sickness
- problems from cold and heat
- allergic and anaphylactic reactions
- lightning strikes
- near drowning
- insect reptile, and animal bites
- poisoning
- emergency child birth

Precautions

In wilderness situations caregivers should follow the maxim of *first, do no harm*. Uninjured members of groups should not attempt rescues that place themselves in danger. People administering first aid or wilderness medicine should remain calm and organized at all times. Only those with experience should administer medications and medical procedures. Injured people should not be moved until they are fully evaluated or unless environmental conditions are threatening and require immediate shelter.

People with certain medical conditions should avoid travel in the wilderness, which can make existing conditions worse. These conditions include metastatic **cancer**, peptic ulcers, **coronary artery disease**, **chronic obstructive pulmonary disease**, clotting or bleeding disorders, high-altitude sickness, chronic **rheumatoid arthritis**, chronic severe back **pain**, and chronic knee and hip joint disease.

Description

The first stage of wilderness medicine begins with an assessment of the injury or condition. Primary assessment is used to quickly determine if a patient is in a life-threatening situation and to provide immediate emergency care. Secondary assessment is the thorough evaluation of a patient after life-threatening circumstances are relieved.

Primary assessment

A rule of thumb for the first steps of primary assessment, recommended by the Wilderness Medicine Institute, is the ABCDE procedure. It stands for Airway, Breathing, Circulation, Disability, and Exposure assessment. First, a patient's airway should be checked by close observation of whether or not air can move in and out and any obstructions to

breathing should be alleviated. In unconscious people the tongue can often fall to the back of the throat and block breathing, so the head should be tilted back and the lower jaw raised to alleviate the obstruction. If neck or spinal cord injuries are suspected, the head must be handled with extreme care to avoid further injury to the delicate spinal cord. In these cases, the lower jaw can be pulled forward to open the airway. If the neck is severely out of alignment due to an injury or fall, it may be gently realigned to free the airway.

After the airway is cleared and breathing is ensured, a patient's circulation is checked by noting the pulse of the carotid artery, on the neck, the pulse of the femoral artery in the front groin, and by listening to the heartbeat. If pulse is lacking, **cardiopulmonary resuscitation** (CPR) may be required, which requires chest compression and mouth-to-mouth breathing. Circulation checks include surveying a patient for bleeding. If severe bleeding is present, it should be stopped by direct pressure to the injured area and by elevating the wound level to the heart, if possible.

Disability assessment means checking for damage to the spinal cord, particularly in the cervical region of the neck. Assessment of exposure determines if environmental conditions, such as heat or cold, are immediate threats to a patient's life, which may require actions such as seeking shelter or covering the patient with protective clothing.

Secondary assessment

During this stage, a thorough **physical examination** of the patient is made from head to toe to determine the extent of injuries or problems. Caretakers performing the assessment should write detailed notes in order to inform physicians or emergency workers later. Patients are thoroughly interviewed to determine the scope of problems and any previous medical issues that might be related. Patients should be spoken to calmly to determine their mental states and how well they respond to stimuli. Vital signs such as heart rate and respiration rate should be noted and monitored. The skin should be carefully observed for injuries, **boils**, **rashes**, and discoloration. Red or flushed skin may indicate **fever** or heat-related conditions, while pale or blotchy skin can point to **shock** or **hypothermia**. A bluish tint to the skin may mean a lack of oxygen. **Contact lenses** should be removed from patients in cold conditions, as they can freeze to the eyes. During secondary assessment the patient should be closely monitored over time until improvement is noted or further treatment decisions are made.

KEY TERMS

Anaphylactic shock—Severe allergic reaction characterized by airway constriction, tissue swelling, and lowered blood pressure.

Cardiac arrest—Heart failure or heart attack.

Dislocation—Displacement of bones at a joint.

Envenomation—Exposure to venom by bites or stings from insects, reptiles, and fish.

Wilderness—Large backcountry areas lacking roads, communication and other modern infrastructure.

At all times in wilderness injuries, shock must be watched for and immediately treated.

Shock

In wilderness situations shock should be suspected after traumatic injuries, significant loss of blood due to internal or external bleeding, extreme loss of fluids from **vomiting** or **diarrhea**, heart attacks, and spinal cord injuries. Shock is easiest to alleviate when it is treated early; when not treated properly, it can progress to unconsciousness and **death**. When the likelihood of shock occurs, patients should be continually monitored and supported.

Symptoms of shock begin with **anxiety** and restlessness, with increased heart rates and labored, shallow breathing. Shock victims tend to sweat profusely with cool and clammy skin. Thirst and **nausea** are also symptoms.

Shock is treated in the wilderness by maintaining an open airway for the patient to breathe, by treating any injuries such as bleeding **wounds**, by reducing pain if possible, and by replenishing fluids. Patients should be kept calm and warm, and their feet should be elevated if possible to increase blood flow to the organs. If shock symptoms progress, plans should be quickly made to get help or evacuate the patient.

Evacuation

Evacuation of a patient may be a crucial decision in the wilderness, depending upon the severity of an injury or condition, the difficulty of moving the patient, the time considerations involved, and the availability of outside help. In general, if a patient with severe symptoms is not improving despite care then evacuation becomes necessary. The Wilderness

Medical Society lists symptoms that require postponing travel or evacuating patients:

- progressive deterioration with symptoms of dizziness, fainting, abnormally slow (bradycardia) or fast (tachycardia) heart rate, labored breathing, poor mental status, progressive weakness, constant vomiting or diarrhea, intolerance of oral fluids, or recurrent loss of consciousness due to head injuries
- debilitating pain
- inability to sustain pace due to medical problems
- passage of blood by mouth or rectum
- symptoms of serious high-altitude illness
- infections that get worse despite treatment
- chest pain that is not musculoskeletal in origin
- psychological status threatening the individual or group

If a patient cannot be moved without risk of further injury, then other members of a party, preferably two or more, should be sent to get outside help. When requesting outside assistance, the safety of incoming rescuers and time constraints should be weighed. Requests for outside help should be made in writing, and include an assessment of the patient and situation as well as a detailed location of the incident. In some regions, helicopter evacuation may be an option, and should be used if an injury is life-threatening.

During evacuation patients must be handled with extreme care, as well as insulated from heat, cold, and further injuries. Larger wilderness expeditions may have special devices available for transporting injured members, while smaller parties may have to improvise transporting devices by using backpacks, ropes, and other available materials.

Wounds and burns

In wilderness situations wound management strives to stop bleeding, prevent infection, and speed healing. Bleeding from wounds should be controlled by direct pressure. Wounds and **burns** should be cleaned gently and thoroughly, treated with antibiotic ointment, and covered with **bandages** to avoid infections. Wounds that have high risks of infections, such as large cuts, open **fractures**, and animal **bites**, should be watched closely.

External and internal bleeding

External bleeding should be stopped by direct pressure, such as firmly applying a clean bandage or compress to an open wound. Secondary pressure may be applied to pressure points, such as the large arteries in the upper arm or groin, to slow bleeding. Tourniquets are recommended only in life-threatening situations, as they can cause complications and infections. Symptoms of internal bleeding include **dizziness**, **fainting**, rapid heartbeat, weak pulse, **shortness of breath**, thirst, loss of color, **vomiting** blood, blood in the feces or urine, and severe pain or swelling in the abdomen. If internal bleeding is suspected, medical help should be sought immediately. With all cases of significant blood loss, shock must be carefully considered.

Cardiac arrest

Cardiac arrest in the wilderness may require CPR, although CPR is less effective in remote regions that lack access to the **life support** technology that ambulances quickly supply. CPR should be administered to patients who have suffered near drowning, hypothermia, lightning strikes, and drug overdoses. CPR generally should not be administered in the wilderness if it endangers the rescuers, if the time of the cardiac arrest is unknown, if the patient appears to be dead or rigor mortis has set in, or if cardiac arrest was caused by severe trauma or lethal injuries.

Head injuries

Head injuries that do not cause loss of consciousness in the victim are rarely dangerous. Short-term loss of consciousness following head injuries is known as **concussion**, and these patients should be closely monitored for 24 hours, including waking them every three hours during sleep to check for mental alertness. For head injuries that cause prolonged unconsciousness, the airway and cervical spine must be protected. Severe brain injury is indicated by relapses into unconsciousness, bad headaches, bleeding from the ears, clear fluid draining from the nose, vomiting, persistent disorientation, personality changes, seizures, irregular heartbeat and breathing, and unequal or unreactive pupils. Severe head injuries must be treated by seeking immediate medical help or evacuation.

Spinal cord injuries

If spinal cord injuries are suspected, patients must be immobilized. Some expeditions or rescue teams may carry special splints or vests in their medical kits. If no such equipment is available, *spineboards* may be fashioned from available materials, such as backpacks, poles, or ice axes, to prevent unnecessary movement of the injured backbone.

Fractures and dislocations

Wilderness care for fractures recommends **immobilization** by using splints and slings. If manufactured

splints and slings are not available in the medicine kit, they can be improvised by using natural materials, ski poles, ice axes, clothing, or parts of backpacks. In the case of **dislocations**, standard wilderness procedure is to splint, tape, and stabilize the injury in the current position. However, if circulation or nerve function is impaired, or if the injured person is in extreme pain, relocation may be necessary by realigning the injured area. Relocation is most effective if it is done immediately following the injury, before stiffness or **muscle spasms** set in.

Altitude sickness

Symptoms of **altitude sickness** include **headache**, nausea, **fatigue**, vomiting, and bluish skin. Ataxia, or loss of muscular control and balance indicates more severe altitude sickness. Altitude sickness can occur at altitudes above 8,000 feet. The best prevention of the condition is allowing plenty of time for acclimatization at high altitudes, drinking plenty of fluids, and eating a diet rich in carbohydrates. **Aspirin** or **acetaminophen** may be taken, while the drug acetazolamide (Diamox) can relieve symptoms of mild acute mountain sickness (AMS). Other related conditions, which can cause death, are high altitude cerebral **edema** (HACE), which causes fluid accumulation on the brain, and high altitude **pulmonary edema** (HAPE), which causes fluid in the lungs. The main treatment for acute mountain sickness is to rapidly descend to lower altitudes. In some cases oxygen may be available to ease symptoms.

Problems from cold and heat

Frostbite is localized tissue damage from exposure to cold and is remedied by the slow warming of exposed parts, preferably in heated water. Hypothermia is the condition resulting from lowered body core temperature and is a common affliction in wilderness medicine. Mild hypothermia occurs when the body's core temperature (measured rectally) falls from normal to 95°F (35°C) Fahrenheit. Moderate hypothermia gives temperatures between 90-95°F (32.2-35°C), while severe hypothermia occurs when a body's core temperature falls below 90°F (32.2°C). Symptoms include severe shivering, confusion, apathy, drowsiness, slurred speech, and impaired reflexes and progresses to the point of unconsciousness.

Even cases of the mildest hypothermia must be cared for closely. Patients in whom hypothermia is suspected should be immediately warmed by gently removing wet clothing and providing dry clothing, blankets, and shelter. They should be monitored for body temperature changes. Severe hypothermia cannot be remedied in the wilderness; victims must be immediately and gently evacuated. Warming severe hypothermia victims too quickly is dangerous. Cardiopulmonary resuscitation (CPR) may be initiated on victims of severe hypothermia who have cardiac arrest. In cases of near drowning, hypothermia must always be suspected.

Illness from heat includes heat exhaustion and the more severe heat **stroke**. Symptoms include confusion, rapid weak pulse, cramps, dizziness, nausea, diarrhea, headache, and high measured temperatures. Sweating may or may not occur, and the skin may be clammy and blotched. The principle treatment for heat illness in the wilderness is immediate cooling of the patient, by providing shade, fanning, sponging, and immersion in cold water. Heat exhaustion will correct itself with enough rest and water. Heat stroke is life threatening and requires immediate cooling and rehydration with fluids, preferably intravenous ones. Prevention of heat illness includes proper conditioning, protective clothing, and avoiding **dehydration**.

Insect, reptile, and animal bites

Wilderness medicine must deal with an array of **bites and stings**, from bears, snakes, reptiles, spiders, scorpions, bees, fish, and ticks. Prevention includes knowledge of the threats in the region being explored, as well as packing appropriate supplies such as bee sting kits for anaphylactic shock and snakebite kits for venomous attacks. The goal of treatment is to stop bleeding, prevent infection, and alleviate envenomation, or exposure to poison. The Sawyer Extractor is a suction tool used to remove snake venom, while the Epipen and Ana-kit are available by prescription for anaphylactic shock due to **stings** and severe allergic reactions.

Preparation

Knowledge and sound planning can be the difference between success and disaster in the backcountry. Members of extended wilderness outings should undergo thorough examinations by their physicians and dentists prior to undertaking expeditions. People going on wilderness outings should begin in a state of sound physical fitness by undertaking appropriate conditioning programs, as well as becoming acclimatized to special conditions such as altitude or extreme temperatures. Those with medications should be aware of potential side effects and complications, and inform other members of their group. At least two, and preferably all, members of wilderness expeditions should be familiar with first aid, wilderness medicine and rescue procedures. All members of wilderness outings should

carry appropriate clothing, equipment, food, water, and first aid supplies. Trip itineraries should be recorded with park rangers or other official services. Means of communication with rescue facilities should be considered in advance in case emergencies arise.

Carrying adequate medical supplies is a crucial preparation for wilderness outings. These supplies will vary depending on the length of the trip and the region. Medical kits should contain basic first aid supplies, such as bandages, **dressings**, pain relievers, water purification tablets, sunscreen, **antiseptics**, and ointments. Additional medical supplies include **antibiotics**, medications for gastrointestinal problems, **antihistamines,** and emergency kits for **asthma** or allergic reactions, snake and insect bite kits, splints, and basic surgical supplies. Extended expeditions or those facing extreme conditions might include intravenous fluids, oxygen bottles for altitude problems, rescue gear and evacuation equipment, and specific medications for regional diseases and infections, such as **malaria**.

Immunizations are a very important preparation for those entering wilderness areas, particularly in Third World countries. Immunizations should be planned as far in advance as possible, as some take several weeks to become effective and others cannot be given together. Some immunizations that may be required, depending on the region, include **tetanus**, poliovirus, **measles**, **mumps**, **rubella**, **cholera**, **yellow fever**, meningococcus, hepatitis, bubonic **plague**, **typhoid fever,** and **rabies**. See Resources at the end of this article for sources of specific immunization information.

Several organizations provide training and certification for various levels of wilderness medicine. The most basic levels of preparation are first aid and first responder certifications, followed by outdoor emergency care (OEC) training. More rigorous training provides the wilderness first responder (WFR), the wilderness emergency medical technician (WEMC), or the wilderness prehospital emergency care (WPHEC) certifications. The most advanced level of wilderness medical certification is search and rescue (SAR) emergency care, which provides expertise in a sophisticated array of rescue techniques and equipment.

Wilms' tumor

Definition

Wilms' tumor is a cancerous tumor of the kidney that usually occurs in young children. This tumor type is named for the German surgeon Max Wilms (1867–1918) and is also known as a nephroblastoma.

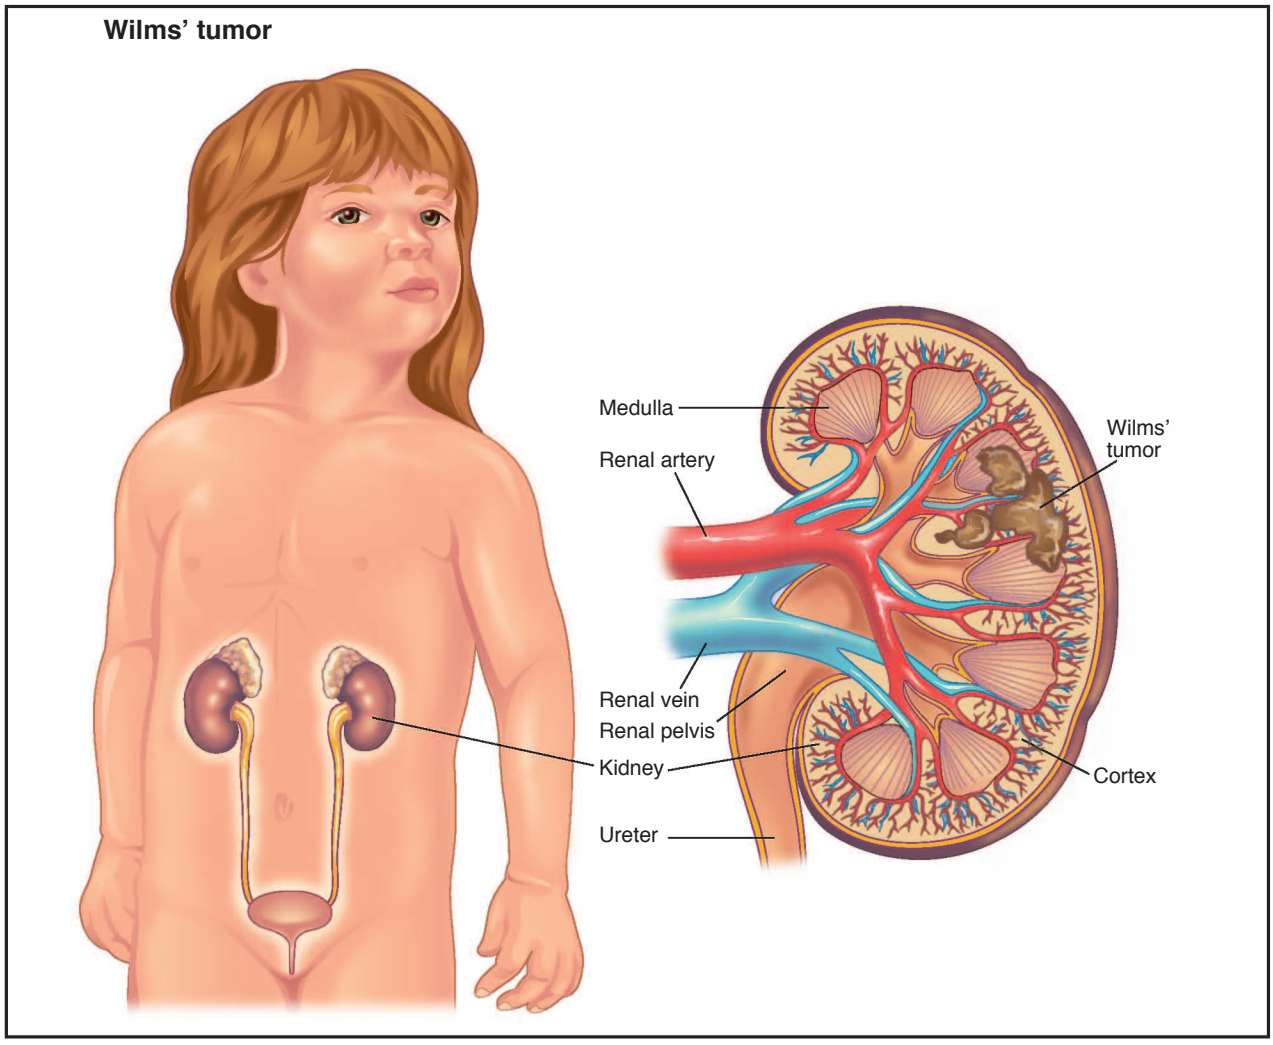
Demographics

Wilms' tumor occurs almost exclusively in young children. The average patient is about three years old, although cases have been reported in infants younger than six months and in adults in their early twenties. It is uncommon for this type of **cancer** to be diagnosed after age six years. Incidence of Wilms' tumor is slightly higher among African Americans and females. In the United States, about 500 new cases are diagnosed annually—the incidence rate has been stable for many years. Wilms' accounts for about 5% of all cancers diagnosed in children in the United States, and it is the most common type of renal cancer in children.

Description

When an unborn baby is developing, the kidneys are formed from primitive cells. Over time, these cells become more specialized. The cells mature and organize into normal kidney structure. Sometimes, clumps of these cells remain in their original, primitive form. If these cells begin to multiply after birth, they may ultimately form a large mass of abnormal cells. This is known as a Wilms' tumor.

Wilms' tumor is a type of malignant tumor, which means that it is made up of cells that are significantly immature and abnormal. These cells are also capable of invading nearby structures within the kidney and



Wilms' tumor. *((Illustration by Electronic Illustrators Group. Reproduced by permission of Gale, a part of Cengage Learning.)*

traveling out of the kidney into other structures. Malignant cells can even travel through the body to invade other organ systems, most commonly the lungs and brain. These features of Wilms' tumor make it a type of cancer that, without treatment, eventually causes **death**. However, advances in medicine during the last 20 years have made Wilms' tumor a very treatable form of cancer.

There are three types or variants of Wilms' tumors: those cases that develop sporadically; tumors that develop as part of genetic syndromes; and those that are familial or hereditary in nature. Most Wilms' tumors develop independent of genetic syndromes or family history although familial Wilms' tumor can be very common in some families.

Wilms' tumors may be found in patients with other types of **birth defects**. These defects include:

- absence of the colored part (the iris) of the eye (aniridia)
- enlargement of one arm, one leg, or half of the face (hemihypertrophy)
- certain birth defects of the urinary system or genitals
- certain genetic syndromes (WAGR syndrome, Denys–Drash syndrome, and Beckwith–Wiedemann syndrome)

Causes and symptoms

The cause of Wilms' tumor is not completely understood. Because 15% of all patients with this type of tumor have other heritable defects, it seems clear that at least some cases of Wilms' tumor are due to an inherited alteration. A genetic defect known as WT1, the Wilms' tumor suppressor gene, has been identified in some patients on chromosome 11p13. It

appears that the tendency to develop a Wilms' tumor can run in families. In fact, about 1.5% of all children with a Wilms' tumor have family members who have also had a Wilms' tumor. The genetic mechanisms associated with the disease are unusually complex. Researchers believe that the tumor develops because the defective WT1 gene fails to stop its growth.

Some patients with Wilms' tumor experience abdominal **pain**, **nausea**, **vomiting**, high blood pressure, or blood in the urine. However, the parents of many children with this type of tumor are the first to notice a firm, rounded mass in their child's abdomen. This discovery is often made while bathing or dressing the child and frequently occurs before any other symptoms appear. Rarely, a Wilms' tumor is diagnosed after there has been bleeding into the tumor, resulting in sudden swelling of the abdomen and a low red blood cell count (anemia).

About 4-5% of Wilms' tumor cases involve both kidneys during the initial evaluation. The tumor appears on either side equally. When pathologists look at these tumor cells under the microscope, they see great diversity in the types of cells. Some types of cells are associated with a more favorable outcome in the patient than others. In about 15% of cases, physicians find some degree of cancer spread (metastasis). The most common sites in the body where metastasis occurs are the liver and lungs.

Researchers have found evidence that certain types of lesions occur before the development of the Wilms' tumor. These lesions usually appear in the form of stromal, tubule, or blastemal cells.

KEY TERMS

Biopsy—A procedure in which a small sample of tissue is removed, prepared, and examined with a microscope to determine the characteristics of the tissue's cells.

Blastemal—An immature material from which cells and tissues develop.

Cancer—A process in which abnormal cells within the body begin to grow out of control, acquire the ability to invade nearby structures, and travel through the bloodstream and invade distant structures.

Malignant—Refers to cancer or cancer cells.

Sarcoma—A type of cancer that originates from connective tissue such as bone or muscle.

Stromal—A type of tissue that is associated with the support of an organ.

Tubule—Tissues and cells associated with the structures that connect the renal pelvis to the glomeruli.

Diagnosis

Children with Wilms' tumor generally first present to physicians with a swollen abdomen or with an obvious abdominal mass. The physician may also find that the child has **fever**, bloody urine, or abdominal pain. The physician will order a variety of tests before imaging is performed. These tests mostly involve blood analysis in the form of a **white blood cell count**, **complete blood count**, coagulation profile, **platelet count**, and serum **calcium** evaluation. Liver and kidney function testing will also be performed, as well as a **urinalysis**. Other tests which may be ordered include testing for chromosome analysis and gene mapping.

Initial diagnosis of Wilms' tumor is made by looking at the tumor using various imaging techniques. Ultrasound, **computed tomography scans** (CT scans), and **magnetic resonance imaging** (MRI) are helpful in diagnosing Wilms' tumor. Final diagnosis, however, depends on obtaining a tissue sample from the mass (biopsy) and examining it under a microscope in order to verify that it has the characteristics of a Wilms' tumor. This biopsy is usually done during surgery to remove or decrease the size of the tumor. Other studies (chest x rays, CT scan of the lungs, bone scans) may also be done in order to see if the tumor has spread to other locations.

Treatment

In the United States, treatment for Wilms' tumor almost always begins with surgery to remove or decrease the size of the kidney tumor. Except in patients who have tumors in both kidneys, this surgery usually requires complete removal of the affected kidney. During surgery, the surrounding lymph nodes, the area around the kidneys, and the entire abdomen will also be examined. While the tumor can spread to these surrounding areas, it is less likely to do so as compared to other types of cancer. In cases where the tumor affects both kidneys, surgeons try to preserve the kidney with the smaller tumor by removing only a portion of the kidney, if possible. Additional biopsies of these areas may be done to see if the cancer has spread. The next treatment steps depend on whether and where the cancer has spread. Samples of the tumor

are also examined under a microscope to determine particular characteristics of the cells making up the tumor.

Information about the tumor cell type and the spread of the tumor is used to decide the best kind of treatment for a particular patient. Treatment is usually a combination of surgery, medications used to kill cancer cells (**chemotherapy**), and x rays or other high–energy rays used to kill cancer cells (**radiation therapy**). These therapies are called adjuvant therapies, and this type of combination therapy has been shown to substantially improve outcome in patients with Wilms' tumor. It has long been known that Wilms' tumors respond to radiation therapy. Likewise, some types of chemotherapy have been found to be effective in treating Wilms' tumor. The most effective drugs include dactinomycin, doxorubicin, and vincristine. Cyclophosphamide can be added to the treatment regimen if the tumor is comprised of an unfavorable tumor type or if the cancer is in an advanced stage. The chemotherapy drugs cyclophosphamide, ifosfamide, cisplatin, carboplatin, and etoposide can be used to treat patients once they have relapsed following initial treatment. Chemotherapy may be administered preoperatively to some patients, specifically for patients with tumor in both kidneys and to treat large tumors that are considered to be inoperable initially.

The National Wilms' Tumor Study Group (NWTSG) has developed a staging system to describe Wilms' tumors. All of the stages assume that surgical removal of the tumor has occurred. Stage I involves "favorable" Wilms' tumor cells and is usually treated successfully with combination chemotherapy involving dactinomycin and vincristine for 18 weeks and without abdominal radiation therapy. Stage II tumors involving a favorable histology (cell characteristics) are usually treated with the same therapy as Stage I with the addition of the chemotherapy drug doxorubicin and are treated for 24 weeks. Stage III tumors with favorable histology are usually treated with combination chemotherapy consisting of doxorubicin, dactinomycin, and vincristine for 24 weeks, along with radiation therapy to the abdomen. Stage IV disease with a favorable histology is generally treated with combination chemotherapy with dactinomycin, doxorubicin, and vincristine. These patients usually receive abdominal radiation therapy and lung radiation therapy if the tumor has spread to the lungs. Patients in Stage IV with a favorable histology will also receive prophylactic administration of the antibiotic drug sulfamethoxazole and trimethoprim (Bactrim) to prevent infection with Pneumocystis carinii.

In the case of Stage II through IV tumors with unfavorable, or anaplastic, cells, then the previously mentioned combination chemotherapy is used along with the drug cyclophosphamide for 24 months. These patients also receive lung radiation therapy if the tumor has spread to the lungs as well as radiation to the abdomen. Another type of tumor cell can be present in Stages I through IV. This cell type is called clear cell sarcoma of the kidney. If this type of cell is present, then patients receive combination therapy with vincristine, doxorubicin, and dactinomycin. All of these patients receive abdominal radiation therapy and lung radiation therapy if the tumor has spread to the lungs.

Prognosis

The prognosis for patients with Wilms' tumor is quite good compared to the prognosis for most types of cancer. The overall survival rate has risen to approximately 90% during the past three decades. Patients who have the best prognosis are usually those who have a small-sized tumor, a favorable cell type, are young (especially under two years old), and have an early stage of cancer that has not spread. Modern treatments have been especially effective in the treatment of this cancer.

Genetic factors can be used to help determine the prognosis in some children diagnosed with Wilms' tumor. Children with genetic changes on chromosomes 1p and 16q, about 5% of children diagnosed with favorable-histology Wilms' tumor, appear to be at greater risk for relapse after initial treatment and are at greater risk of dying than children without these chromosomal changes.

Prevention

There are no known ways to prevent a Wilms' tumor, although it is important that children with birth defects associated with Wilms' tumor be carefully monitored. Some clinicians recommend screening using ultrasounds of the kidneys once or twice per year.

Wilson disease

Definition

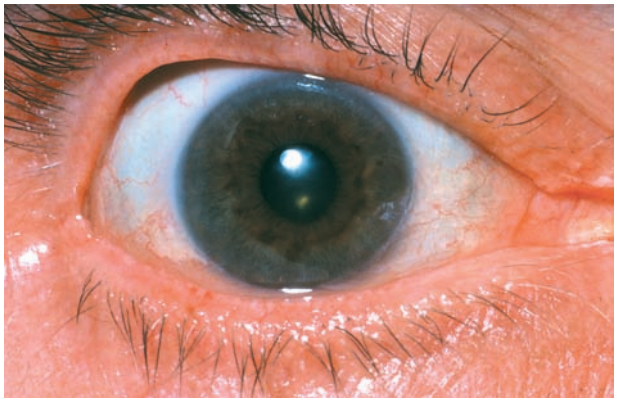
Wilson disease, or WD, is a rare inherited disorder that causes excess copper to accumulate in the body. It is also known as hepatolenticular degeneration. Steadily increasing amounts of copper circulating in the blood are deposited primarily in the brain, liver, kidneys, and the cornea of the eyes. WD is fatal if it is not recognized and treated. It is named for a U.S. neurologist, Samuel A. K. Wilson, who first described it in 1912.

Description

Under normal conditions, copper that finds its way into the body through the diet is processed within the liver. This processed form of copper is then passed into the gallbladder, along with the other components of bile (a fluid produced by the liver, which enters the small intestine in order to help in digestive processes). When the gallbladder empties its contents into the first part of the small intestine (duodenum), the copper in the bile enters and passes through the intestine with the waste products of digestion. In healthy individuals, copper is then passed out of the body in stool.

In Wilson disease, copper does not pass from the liver into the bile, but rather begins to accumulate within the liver. As copper levels rise in the liver, the damaged organ begins to allow copper to flow into the bloodstream, where it circulates. Copper is then deposited throughout the body, building up primarily in the kidneys, the brain and nervous system, and the eyes. Wilson disease, then, is a disorder of copper **poisoning** occurring from birth.

Wilson disease affects approximately 1 in 30,000 to 1 in 100,000 individuals and can affect people from many different populations. Approximately one in 90 individuals are carriers of the gene for Wilson disease.



Copper deposits are visible as a ring around the iris in patients with Wilson disease. *(Photo Researchers, Inc.)*

Causes and symptoms

Wilson disease is inherited in an autosomal recessive manner. Autosomal recessive refers to the pattern of inheritance where each parent carries a gene for the disease on one of his or her chromosome pairs. When each parent passes on the chromosome with the gene for Wilson disease, the child will be affected with the disease. Both males and females can be affected with Wilson disease. If an individual is a carrier of the Wilson disease gene they do not have any symptoms of this disease. In order to be affected, an individual must inherit two copies of the gene, one from each parent. Many cases of Wilson disease may not be inherited but occur as a spontaneous mutation in the gene.

The gene for Wilson disease is located on chromosome number 13. The name of the gene is called ATP7B and is thought to be involved in transporting copper. More than 200 different mutations of this gene have been identified, making diagnosis by **genetic testing** difficult.

Symptoms typically present between the ages of 3 and 60, with age 17 considered to be the average age a diagnosis is made. About half of all patients experience their first symptoms in the liver. The illness causes swelling and tenderness of the liver, sometimes with **fever**, mimicking more common disorders, such as viral hepatitis and **infectious mononucleosis**. Abnormal levels of circulating liver enzymes reveal that the liver is being seriously damaged. This form of damage is referred to as fatty degeneration. Without medical intervention, the liver damage will progress to actual **cirrhosis**. An often-fatal manifestation of **liver disease** is called fulminant hepatitis. This extremely severe inflammation of the liver (hepatitis) results in **jaundice**, fluid leaking into the abdomen, low protein circulating in the blood, abnormalities of the blood clotting system, swelling of the brain, and anemia due to the abnormal destruction of red blood cells.

Neurological symptoms are the first to occur in half of all patients due to copper accumulation in the brain and nervous system. The average age of onset for neurological symptoms is 21. These symptoms include **tremors** of the hands, uncontrollable movements of the limbs, stiffness, drooling, difficulty swallowing, difficulty talking, and **headache**. There is no change in patient's intelligence.

About one-third of all patients with Wilson disease have a variety of psychiatric symptoms as the first signs of the disease. These symptoms include inability to cope, depression, irritability, increased anger, and inappropriate behavior. Often times patients have trouble completing tasks at work or in school.

Other symptoms that can affect patients with Wilson disease, and may occur before or after a diagnosis has been made, include joint disorders, symptoms of arthritis, and skeletal problems such as **osteoporosis**. Patients have occasionally been affected with **kidney stones**, abnormal handling of glucose in their body, and women have menstrual cycle irregularities including stopping their regular cycle temporarily.

Diagnosis

The diagnosis of Wilson disease can be performed relatively easily through several different tests; however, because Wilson disease is so rare, diagnosis is often unfortunately delayed. The tests used to diagnose Wilson disease can be performed on patients who have and who have not already shown symptoms of the disease. It is extremely important to make a diagnosis as soon as possible since liver damage can occur before there are any signs of the disease.

An easy way to diagnose Wilson disease is to measure the amount of a glycoprotein found in the blood called ceruloplasmin. Low levels of ceruloplasmin can diagnose the disease in about 80% of affected patients. This procedure is not as effective for women taking birth control pills, pregnant women, or infants younger than six months of age.

A second test involving an **eye examination** to detect a characteristic ring of copper deposited in a membrane of the cornea (referred to as Kayser-Fleischer rings) is very easy to perform and is very useful in diagnosing patients who have already exhibited symptoms. This test is not as effective in persons without symptoms. This diagnostic test cannot be used by itself to make a diagnosis because some patients with liver disease but not Wilson disease will test positive.

A third test for diagnosing Wilson disease involves measuring the amount of copper in the liver. This can be accomplished by sampling a portion of the liver, called a biopsy. This is one of the most effective ways in which to diagnose Wilson disease, but the procedure itself is more difficult to perform than the others.

Other tests are also useful, for example measuring the amount of copper passed into the urine daily (high in Wilson disease). Another lab test measures the ability of a patient's ceruloplasmin to bind with a form of copper (decreased in Wilson disease). Finally, as discussed under genetic profile, some patients can be diagnosed through a DNA test to determine whether or not they carry two genes for Wilson disease. This

KEY TERMS

Anemia—A blood condition in which the level of hemoglobin or the number of red blood cells falls below normal values. Common symptoms include paleness, fatigue, and shortness of breath.

Bile—A substance produced by the liver, and concentrated and stored in the gallbladder. Bile contains a number of different substances, including bile salts, cholesterol, and bilirubin.

Biopsy—The surgical removal and microscopic examination of living tissue for diagnostic purposes.

Cell—The smallest living units of the body which group together to form tissues and help the body perform specific functions.

Ceruloplasmin—A protein circulating in the bloodstream that binds with copper and transports it.

Chelation therapy—A method of removing copper or other heavy metals from the body by giving medications that bind to the metal and allow it to be excreted.

Chromosome—A microscopic thread-like structure found within each cell of the body and consists of a complex of proteins and DNA. Humans have 46 chromosomes arranged into 23 pairs. Changes in either the total number of chromosomes or their shape and size (structure) may lead to physical or mental abnormalities.

Cirrhosis—A chronic degenerative disease of the liver, in which normal cells are replaced by fibrous tissue. Cirrhosis is a major risk factor for the later development of liver cancer.

Deoxyribonucleic acid (DNA)—The genetic material in cells that holds the inherited instructions for growth, development, and cellular functioning.

Gallbladder—A small, pear-shaped organ in the upper right hand corner of the abdomen. It is connected by a series of ducts (tube-like channels) to the liver pancreas, and duodenum (first part of the small intestine). The gallbladder receives bile from the liver and concentrates and stores it. After a meal, bile is squeezed out of the gallbladder into the intestine, where it aids in digestion of food.

Gene—A building block of inheritance, which contains the instructions for the production of a particular protein, and is made up of a molecular sequence found on a section of DNA. Each gene is found on a precise location on a chromosome.

Glucose—One of the two simple sugars, together with galactose, that makes up the protein, lactose, found in milk. Glucose is the form of sugar that is usable by the body to generate energy.

Hepatitis—A viral disease characterized by inflammation of the liver cells (hepatocytes). People infected with hepatitis B or hepatitis C virus are at an increased risk for developing liver cancer.

Jaundice—Yellowing of the skin or eyes due to excess of bilirubin in the blood.

Toxic—Poisoinous.

test does not always prove to be useful in certain patients and is of most use when used to test the brothers and sisters of affected patients.

Molecular genetic testing is not particularly valuable in diagnosing WD because of the large number of possible gene mutations.

Treatment

Treatment involves life-long administration of either D-penicillamine (Cuprimine, Depen) or trientine hydrochloride (Syprine). Both of these drugs remove copper deposits throughout the body by binding to the copper which then leaves the body in the urine. This type of treatment is called **chelation therapy**. Zinc acetate (Galzin) and a low copper diet are other ways in which to treat Wilson disease.

Penicillamine has a number of serious side effects:

- joint pain
- neurological problems
- systemic lupus erythematosus
- decreased production of all blood elements
- interference with clotting
- allergic reactions

Careful monitoring is necessary. When patients have side effects from penicillamine, the dose can sometimes be lowered to an effective level that causes fewer difficulties. Alternatively, steroid medications may be required to reduce certain sensitivity reactions. Trientine has fewer potential side effects, but must still be carefully monitored.

Treatment with zinc acetate is also an effective way to remove excess copper from the body. Zinc is a metal that works to block copper absorption and bind copper in the intestinal cells until it is all released into the stool approximately one week later. The benefit of treatment with zinc is there are no toxic side effects however the zinc is a slower acting agent than the other drugs. It takes four to eight months for the zinc to be effective in reducing the overall amount of copper in the body.

Finally, patients with Wilson disease are encouraged to follow a diet low in copper, with an average copper intake of 1.0 mg per day. Foods to be avoided for the high levels of copper include liver and shellfish. Patients are also instructed to monitor their drinking water for excess levels of copper and drink distilled water instead.

Patients may be given a liver transplant in the event of liver failure as a complication of WD. **Liver transplantation** has been reported to have a relatively favorable outcome, in some cases decreasing the patient's neurologic symptoms.

Prognosis

Without treatment, Wilson disease is always fatal. With treatment, symptoms may continue to worsen for the first six to eight weeks. After this time, definite improvement should begin to be seen. However, it may take several years (two to five) of treatment to reach maximal benefit to the brain and liver. Even then, many patients are not returned to their original level of functioning. Patients with Wilson disease need to maintain some sort of anticopper treatment for the rest of their lives in order to prevent copper levels from rising in the body. Interruptions in treatment can result in a relapse of the disease which is not reversible, and can ultimately lead to **death**.

Wiskott-Aldrich syndrome

Definition

Wiskott-Aldrich syndrome (WAS) is a rare inherited disorder **immunodeficiency** disorder marked by a low level of blood platelets (**thrombocytopenia**), **eczema**, recurrent infections, and a high risk of leukemia or lymph node tumors.

Demographics

WAS syndrome is rare. It affects about 1 in every 250,000 male children and occurs worldwide. Children are born with the genetic defect that causes this syndrome and usually do not live beyond childhood.

Description

WAS is named for the two physicians who first reported the disorder. In 1937, Dr. A. Wiskott, a physician working in Munich, Germany, described two affected boys of German ancestry who had repeated infections, a skin rash, and poor blood-clotting ability. Nearly 20 years later, Dr. R. A. Aldrich reported similar symptoms in members of a U.S. family of Dutch ancestry.

WAS is inherited as a rare X-linked genetic disorder and therefore affects only males. The gene responsible

for WAS, officially called the Wiskott-Aldrich syndrome (eczema-thrombocytopenia) gene or WAS gene, is located on the short arm of the X chromosome. Since males have only one X chromosome, they have only one copy of the genes on this chromosome. If their copy of the WAS gene is abnormal, they will have WAS. In contrast, females have two X chromosomes. They can have a normal copy of the WAS gene on one chromosome, even if they have an abnormal WAS gene on the other. Because the defective gene that causes WAS is rare and usually causes **death** in childhood, it is highly unlikely that a female will have two defective copies of the gene. The single normal copy of the WAS gene on one X chromosome is sufficient to prevent females from having WAS. However, women who have one abnormal copy of the WAS gene are designated as carriers. While they will not have WAS, they have a 50% chance of passing the gene to each of their sons who will have WAS. Carrier females also have a 50% risk of passing the defective copy of the gene to their daughters who also become carriers.

Researchers identified the gene for WAS in 1994 and pinpointed its location on the short arm of the X chromosome. As of 2010, over 250 different mutations have been found in the gene among WAS patients. The fact that there are many mutations may explain some of the variability of symptoms among boys with WAS. However, even within the same family, affected individuals with the identical WAS gene mutation may have different degrees of severity of the disease. The mild form, called X–linked thrombocytopenia, is also caused by mutations in this same gene.

Causes and symptoms

The syndrome is caused by a defect (mutation) in a specific gene called the WAS gene that normally codes for the protein named Wiskott-Aldrich Syndrome Protein (WASP). This vital protein is a component of cells that are important in the body's defense against infection (lymphocytes). The same protein also functions in cells that help prevent bleeding (platelets). A less severe form of the disease, X–linked thrombocytopenia, affects mainly platelets.

Increased susceptibility to infections, eczema, and excessive bleeding are hallmarks of WAS, although symptoms can vary significantly from one patient to another. The immune system of patients with WAS produces too few B and T cells. B cells are cells in the body that make antibodies. There are many types of T cells. Both B and T cells are needed to defend the body against infection. Because both types of cells are affected, WAS patients are subject to repeated infections from bacteria, fungi, and viruses. Ear infections, **meningitis**, and **pneumonia** are common in boys with WAS.

WAS patients also have thrombocytopenia, a decreased number of platelets. Platelets are specialized blood cells that help to form **blood clots** and prevent uncontrolled bleeding. The platelets also may be smaller than normal. Some of the earliest symptoms of the syndrome are hemorrhage from **circumcision**, bloody **diarrhea**, and a tendency to bruise very easily.

Anemia and an enlarged spleen (splenomegaly) are seen in some patients. About 10% of patients develop malignancies (cancers), usually leukemia or tumors in the lymph nodes (non–Hodgkin's lymphoma).

Diagnosis

The diagnosis of WAS is usually suspected in male infants who have excessive bleeding, eczema, and frequent bacterial or viral infections. Special blood tests can then be ordered to confirm WAS. The blood of Wiskott-Aldrich patients will show a low **platelet count** and a weak immune (antibody) response. It is also possible to confirm the diagnosis by obtaining a small sample of the patient's blood and analyzing the DNA for a mutation in the WAS gene. Knowledge of the exact mutation combined with information about how much WAS protein the defective gene can produce may help predict how severe a form of the disease an individual will have.

Carrier Testing

If the specific WAS gene mutation is identified in an affected child, that child's mother can then be tested to confirm that she carries the gene. Other members of the mother's family may also want to consider testing to find out if they carry the same gene mutation. The first step in studying other family members is for a geneticist or genetic counselor to obtain a detailed family history and construct a pedigree (family tree) to determine which family members should be offered testing.

Prenatal Diagnosis

In families where one child has been born with WAS, prenatal testing should be offered in subsequent pregnancies. There is a 50% chance with each

KEY TERMS

Amniocentesis—A procedure performed at 16–18 weeks of pregnancy in which a needle is inserted through a woman's abdomen into her uterus to draw out a small sample of the amniotic fluid from around the baby. Either the fluid itself or cells from the fluid can be used for a variety of tests to obtain information about genetic disorders and other medical conditions in the fetus.

Anemia—A blood condition in which the level of hemoglobin or the number of red blood cells falls below normal values. Common symptoms include paleness, fatigue, and shortness of breath.

B cells (B lymphocytes)—a type of white blood cell that produces antibodies.

Chorionic villus biopsy—A procedure used for prenatal diagnosis at 10–12 weeks gestation. Under ultrasound guidance a needle is inserted either through the mother's vagina or abdominal wall and a sample of cells is collected from around the early embryo. These cells are then tested for chromosome abnormalities or other genetic diseases.

Eczema—Inflammation of the skin with redness and other variable signs such as crusts, watery discharge, and itching.

Gene—A building block of inheritance which contains the instructions for the production of a particular protein and is made up of a molecular sequence found on a section of DNA. Each gene is found on a precise location on a chromosome.

Immune system—The mechanism that protects the body from foreign substances, foreign cells, and pathogens. The thymus, spleen, lymph nodes, white blood cells, including the B cells and T cells, and antibodies are involved in the immune response, which aims to destroy these foreign bodies.

Mutation—A permanent change in the genetic material that may alter a trait or characteristic of an individual, or manifest as disease, and can be transmitted to offspring.

Platelets—Small disc–shaped structures that circulate in the blood stream and participate in blood clotting.

Prenatal diagnosis—The determination of whether a fetus possesses a disease or disorder while it is still in the womb.

Syndrome—A group of signs and symptoms that collectively characterize a disease or disorder.

T cells (T lymphocytes)—White blood cells that originate in the thymus gland. T cells regulate the immune system's response to infections, including HIV. CD4 lymphocytes are a subset of T lymphocytes.

Thrombocytopenia—A persistent decrease in the number of blood platelets usually associated with hemorrhaging.

X–linked—Located on the X chromosome, one of the sex chromosomes. X–linked genes follow a characteristic pattern of inheritance from one generation to the next.

subsequent **pregnancy** that the mother, who is a carrier, will transmit the abnormal copy of the gene to her baby. The key is to first identify the particular WAS gene mutation in the child with WAS. Then, early in a pregnancy, cells can be obtained from the developing fetus by **chorionic villus sampling** or **amniocentesis**, and checked for the same mutation. Women who carry the abnormal WAS gene and are considering prenatal diagnosis should discuss the risks and benefits of this type of testing with a geneticist or genetic counselor.

Treatment

Standard treatments for individuals with WAS include **antibiotics** for infections and platelet transfusions to limit bleeding. Immune globulin is given to strengthen the individual's immune system. Eczema can be treated with corticosteroid creams applied directly to the skin. The spleen is sometimes removed to reduce the risk of bleeding. In individuals with WAS, however, removal of the spleen also increases the risk of infection unless antibiotics are given to prevent infections.

About 50% of individuals with WAS are helped by treatment with transfer factor, which is a substance derived from the T cells of a healthy person. Transfer factor is given to improve both blood clotting and immune functions. **Bone marrow transplantation** has been successful in a number of cases. It has been most successful in boys under five years of age where the donor is a sibling whose tissue type closely matches that of the individual with WAS. Bone marrow

transplantation can cure this condition but a highly matched donor must be found, transplantation should occur before age five, and the procedure carries substantial risks. Investigation into treatment with **gene therapy** is ongoing as of 2010.

Prognosis

Prognosis for males diagnosed with Wiskott-Aldrich syndrome who do not undergo successful bone marrow transplantation is poor. The average individual lives about six years; those who survive into adolescence often develop **cancer**. Death usually occurs from severe bleeding or overwhelming infection in the first few years of life.

Prevention

Wiskott-Aldrich syndrome is a genetic defect present at birth and cannot be prevented.

Withdrawal syndromes

Definition

Withdrawal syndrome occurs in drug and alcohol addicted individuals who discontinue or reduce the use of their drug of choice. This process of eliminating drugs and alcohol from the body is known as **detoxification**. **Anxiety**, **insomnia**, **nausea**, perspiration, body aches, and **tremors** are just a few of the physical and psychological symptoms of drug and alcohol withdrawal that may occur during detoxification.

Description

Drugs and alcohol affect mood by altering brain chemistry, specifically the production of neurotransmitters. Neurotransmitters are chemicals in the central nervous system that enable nerve impulses to travel through the central nervous system and regulate thought processes, behavior, and emotion. Drugs that temporarily elevate neurotransmitter levels are called stimulants. Drugs that decrease neurotransmitter levels and depress the central nervous system are called depressants; they include opiates and sedative-hypnotic drugs such as alcohol and **barbiturates**. (There are exceptions: benzodiazepine elevates the level of an inhibitory neurotransmitter, GABA, therefore it serves as a tranquilizer.)

When drug or alcohol consumption becomes chronic, the body adjusts to the constant presence of the substance by changing its normal production of neurotransmitters. If drug and alcohol use suddenly stops, the body and central nervous system react to the absence of the substance with an array of symptoms known collectively as withdrawal syndrome.

Causes and symptoms

Acute withdrawal syndrome begins within hours of abstinence and includes a full range of physical and psychological symptoms. More long-term, or subacute, withdrawal symptoms, such as intense drug craving, may occur weeks or months after detoxification has taken place.

Alcohol withdrawal

Alcohol withdrawal syndrome occurs in alcohol-dependent individuals who suddenly stop or dramatically reduce their alcohol intake. The onset of the syndrome is likely to occur within a week, but usually occurs within 24 hours of the individual's last drink and is triggered when the central nervous system attempts to adjust to the sudden absence of ethyl

alcohol in the body. Symptoms may include extreme anxiety, disorientation, **hallucinations**, **sleep disorders**, hand tremors, nausea, sweating, seizures, and racing pulse. **Delirium** tremens (DTs) are an extreme example of withdrawal. In the worst cases, untreated alcohol withdrawal syndrome can result in **death**. As many as two million Americans may experience symptoms of alcohol withdrawal conditions each year.

Barbiturate withdrawal

Barbiturates are prescribed as anticonvulsants, sedatives, and general anesthetics. They can also mimic some of the characteristics of alcohol intoxication (including euphoria, elation, and uninhibited behavior), which make them candidates for **abuse**. Commonly abused barbiturates include amobarbital (Amytal), pentobarbital (Nembutal), and secobarbital (Seconal). These drugs depress the respiratory and nervous system functions. Because abusers rapidly build up a tolerance to the effects of the drug, fatal overdose or **coma** can easily occur. Symptoms of withdrawal syndrome appear 12-20 hours after the last dose; they include anxiety, irritability, elevated heart and respiration rate, muscle **pain**, nausea, tremors, hallucinations, confusion, and seizures. Death is a possibility if the condition is left untreated. Because barbiturates decrease REM (rapid eye movement) sleep, during which dreaming takes place, withdrawal often results in sleep disruptions such as nightmares, insomnia, or vivid dreaming.

Opiate withdrawal

Opiates are powerfully addictive analgesic drugs that deaden nerve pathways related to pain. Abusers of propoxyphene (Darvon), meperidine (Demerol), percocet (Oxycodone), heroin, morphine, and other powerfully addictive opiates quickly build up a tolerance to the drugs and need progressively larger doses to achieve the desired effect. Stopping or reducing the intake of the drug can cause severe withdrawal symptoms, which begin six to eight hours after the last dosage. Symptoms are flu-like and include gastrointestinal distress, anxiety, nausea, insomnia, muscle pain, fevers, sweating, and runny nose and eyes.

Stimulant withdrawal

Use of stimulants, such as **cocaine**, crack, amphetamines, and methamphetamines, cause an increase in neurotransmitters in the central nervous system and produce feelings of alertness and increased energy. This initial "rush" is followed by a longer period of neurotransmitter loss, characterized by depression, lethargy, and a craving for more stimulants sometimes called a rebound effect. When a stimulant-dependent individual abstains from stimulant use, withdrawal symptoms, including depression, **fatigue**, insomnia, and loss of appetite, reflect this drop in neurotransmitter levels. Withdrawal typically takes one to two weeks.

Diagnosis

A detailed history of the patient's drug or alcohol use taken before detoxification can be helpful in predicting the severity of withdrawal symptoms. Standardized clinical tests, such as the Clinical Institute Withdrawal Assessment for Alcohol, revised, (CIWA-Ar), are used to evaluate the severity of withdrawal symptoms throughout the detoxification procedure.

Treatment

Pharmacologic and medical management is often recommended for withdrawal syndrome. The physical condition of the patient is closely monitored throughout the detoxification procedure.

Alcohol withdrawal

Alcohol withdrawal syndrome can be treated at home or in a hospital or treatment setting. Inpatient treatment is recommended for patients who are at risk for serious withdrawal symptoms or re-intoxication if treated as an outpatient. Withdrawal symptoms are minimized through the administration of cross-tolerant sedatives. Long-acting **benzodiazepines**, such as diazepam (Valium), chlordiazepoxide (Librium), and lorazepam (Ativan), are the pharmacologic treatments of choice in managing the symptoms of alcohol withdrawal. Drug dosage is adjusted to offset the discomfort of withdrawal, without causing a euphoric effect, and is then gradually decreased as withdrawal symptoms lessen.

Barbiturate withdrawal

Because the risk for seizures and other severe complications is high, barbiturate withdrawal should be monitored in a hospital setting. Patients are given low doses of phenobarbital at a regular interval until mild intoxication is achieved. The dosage amount and frequency is then gradually decreased until withdrawal is complete.

Opiate withdrawal

Two basic treatment approaches are used for managing opiate withdrawal. The first involves treating the symptoms of the withdrawal with appropriate

KEY TERMS

Analgesics—Pain killing drugs that depress respiratory function. Opiates are analgesics.

Antagonist—A substance that tends to nullify the action of another.

Benzodiazepines—Sedatives used to treat anxiety, epilepsy, and alcohol withdrawal syndrome. Diazepam (Valium), alprazolam (Xanax), and chlordiazepoxide (Librium) are all benzodiazepines.

Cross-tolerant—A drug that has the same pharmacological effect as another is considered cross-tolerant. Cross-tolerant drugs are often used in treating withdrawal syndromes.

Detoxification—The process of physically eliminating drugs and/or alcohol from the system of a substance-dependent individual.

Dysphoria—A depressed and anxious mood state.

Neurotransmitters—Chemicals in the brain that affect the nervous system and alter thinking patterns.

Opiates—Analgesic, pain killing drugs, such as heroin and morphine that depress the central nervous system.

medication. Clondine, an antihypertensive drug, is commonly prescribed to reduce muscle pain and cramping. Other symptom-specific drugs are administered on an as-needed basis.

The second treatment option is to replace the patient's drug of choice with **methadone**, a long-acting, cross-tolerant opiate that does not normally produce a "high." Doses of methadone are administered every four to six hours. The patient's reaction is closely observed, and dosages are slowly decreased until withdrawal symptoms have disappeared, then dosages are discontinued. Methadone withdrawal can be completed within three weeks. It is important to note that methadone withdrawal treatment differs from a methadone maintenance program, in which patients who are unwilling to give up opiates are prescribed methadone as a legal, long-term substitute for their drug of choice.

Rapid opiate detoxification (ROD) is an emerging treatment option for opiate withdrawal. The ROD method is reported to be faster and to cause less physical discomfort than traditional forms of opiate detoxification. The treatment is typically performed in a hospital or private clinic setting. Naltrexone, an opiate antagonist that blocks opiate receptors and reverses the effects of opiates, is administered to trigger the withdrawal response. Clonidine is given simultaneously to ease the symptoms of withdrawal. The patient is anesthetized throughout the three to four hour procedure, and withdrawal occurs while the patient sleeps. Vital signs are monitored closely and a ventilator may be employed.

In early 2004, a new single injection method for opiate **addiction** was being tested. It consisted of a slow-release form of buprenorphine and prevented symptoms for an entire month.

Stimulant withdrawal

Because of the depression and dysphoria (feeling of a psychological low) related to stimulant withdrawal, psychological and/or medical management is critical. Treatment may include a regimen of drugs that increase neurotransmitter production.

Prognosis

A closely observed, medically managed detoxification typically results in a safe and tolerable withdrawal experience for the patient. Detoxification is only a short-term solution for obtaining abstinence. An addiction treatment and long-term recovery program is necessary to achieve long-term sobriety. Without such a treatment program, the likelihood of recurrence of abuse, and, therefore, the recurrence of withdrawal syndrome, is high.

Prevention

After detoxification, alcohol and drug dependent individuals are encouraged to maintain their abstinence through participation in **substance abuse** treatment or a 12-step recovery program.

Wolff-Parkinson-White syndrome

Definition

Wolff-Parkinson-White syndrome is an abnormality in the electrical functioning of the heart which may cause rapid heart rates. The abnormality affects the electrical signal between the atria and ventricles.

Description

Blood is circulated through the heart and body by a muscular pump and valve system involving the atria and ventricles. The right atrium receives oxygen-lacking blood returning to the heart from the body. The blood is passed from the right atrium into the right ventricle, which contracts and sends blood out to the pulmonary artery. The pulmonary artery sends the blood into the lungs, where carbon dioxide is removed, and fresh oxygen is added. The left atrium receives blood with oxygen from the lungs and passes this arterial blood to the left ventricle, where it is emptied into the aorta, the main artery of the heart.

These functions are directed by electrical signals within the heart. In patients afflicted with Wolff-Parkinson-White syndrome, an abnormal pathway exists that causes additional electrical signals to pass between the atria and ventricles, possibly causing rapid heart rate.

Causes and symptoms

Congenital heart disease may contribute to this and other **arrhythmias**. Ebstein's anomaly, a congenital heart defect that involves displacement of the tricuspid valve, located on the right side of the heart, is one known cause of Wolff-Parkinson-White syndrome. This anomaly allows blood to flow via the small hole to the other side of the heart. Often, there is no known cause for Wolff-Parkinson-White syndrome. Many people with the syndrome have no symptoms. On the other hand, some people experience temporary rapid heartbeat due to certain drugs, **smoking**, and **anxiety**.

Diagnosis

Electrocardiography (ECG) is used to diagnose Wolff-Parkinson-White syndrome, and other cardiac arrhythmias. A trained physician, normally a cardiologist, can recognize patterns of electrical conduction. With this syndrome, the extra pathway will show a pattern different from those of normal conduction. If no irregular patterns show on the ECG, the patient may be sent home with a 24-hour heart monitor, called a Holter monitor, which will help detect intermittent occurrences. Other studies, such as the cardiac electrophysiologic study (EPS), may be ordered to pinpoint the location of the accessory pathway and to determine a course of treatment.

Treatment

Various drugs may be used to treat Wolff-Parkinson-White syndrome, as well as other cardiac arrhythmias. The purpose of these drugs is to slow the electrical signals and excitation of heart muscles. As some of these drugs may have side effects, including the rare production of new or more frequent arrhythmias, the patient should be carefully observed. Ablative therapies may be accomplished with radiofrequency or cardiac catheters to cut through the tissue which is causing the abnormal electrical signals.

At one time, only open heart surgery was used, but the procedure can be done now with **local anesthesia** in a special cardiac laboratory. In some cases, surgery may still be recommended to treat Wolff-Parkinson-White syndrome.Young people with this syndrome may be treated more successfully with surgery, rather than enduring a lifetime of drug treatments, or the possible threat of **sudden cardiac death**.

Alternative treatment

A provider may teach patients methods to help control heart rate. Relaxation techniques, **acupuncture**, botanical medicine, and homeopathy can all be helpful supportive therapies.

Prognosis

Most patients with this syndrome can lead normal lives, even with episodes of tachycardia. In many cases, the syndrome is secondary to the underlying congenital heart defect. However, Wolff-Parkinson-White syndrome can cause sudden cardiac arrest in certain instances.

KEY TERMS

Ablative—Used to describe a procedure involving removal of a tissue or body part, or destruction of its funtion.

Arrhythmia—Irregular heart beat.

Electrocardiograph (ECG)—A test of a patient's heartbeat that involves placing leads, or detectors, on the patient's chest to record electrical impulses in the heart. The test will produce a strip, or picture record of the heart's electrical function.

Tachycardia—Rapid heart rate, defined as more than 100 beats per minute.

Prevention

If the syndrome is not due to congenital heart disease, the patient may try avoiding behaviors which lead to arrhythmia, such as elimination of **caffeine**, alcohol, **cocaine**, and smoking.

Teresa Odle

Women's health

Definition

Women's health is concerned with how disease and health issues affect women and with diseases and conditions that affect women at higher rates. It promotes the inclusion of gender perspectives in a broad spectrum of health issues.

Description

Generally speaking, both women and men share the same health problems. However, several conditions and diseases affect women differently, either because they experience different symptoms or because the disease may be more common in women, such as **osteoarthritis obesity,** and depression. Other conditions, such as **menopause** and **pregnancy**, are unique to women. Another factor in women's health is consideration of the health consequences of discrimination against women that exist in nearly all cultures.

The average life expectancy has almost doubled for women (79 years for women and 73 years for men), when compared with averages at the beginning of the twentieth century. Because of the gender gap in lifespan, women represent approximately two-thirds of the population older than 65 and three-fourths of the population aged 85 years and older. The reasons for this variance are primarily due to physiological differences among men and women.

During different phases of a woman's life cycle, there are complex interactions between sex hormones, physiological changes, and emotional issues. Physiological changes occur as early as embryonic development when hormones program structural differences between male and female brains. During reproductive years, sex hormones profoundly influence reproduction and development, which creates a spectrum of gender-specific health issues. With advancing age and onset of menopause, women's risk factors for disease is generally similar to men's. Although the same disease may affect women and men equally, biological mechanisms and psychosocial differences can influence the clinical course of a disease differently in women. The number of women working has doubled within the past 50 years. The effect of work **stress**, new environmental exposures and multiple roles is expected to have health and social impact. For example, women are often more stressed than men at work, due to the high demands of having to combine work and family responsibilities.

The leading causes of **death** among women are cardiovascular disease, **cancer**, cerebrovascular disease, chronic lung disease, pneumonia/influenza, and diabetes.

Malignant cancers are the most common cause of premature death among women. **Breast cancer** is the second leading cause of death in women and the most commonly diagnosed cancer. Lung cancer, secondary to cigarette **smoking** is the leading cause of cancer death among women.

Cerebrovascular disease accounts for approximately 6% of all deaths in women and it is the third leading cause of mortality. The least common form of **stroke** in the general population, **subarachnoid hemorrhage**, is more common in women.

The prevalence of cigarette smoking has increased greatly in women and this is correlated with pulmonary

Statistics on women's health

Characteristic	Percentage of U.S. women	Age
In fair or poor health	14%	18+
Without health insurance	15%	<65
Currently smoke	18%	18+
Engage in regular physical activity	30%	18+
Have hypertension	33%	20+
Are obese	35%	20+
Had a mammogram in the past 2 years	68%	40+
Had a Pap smear in the past 3 years	75%	18+

SOURCE: Centers for Disease Control and Prevention, FastStats.

(Table by PreMediaGlobal. Reproduced by permission of Gale, a part of Cengage Learning.)

disease. Death rates for pulmonary disease including cancer and infectious causes of death are expected to rise for women.

Diabetes, a leading cause of death in women is more prevalent among Hispanic, African-American, and Native American women. Past age 45, diabetes affects about one in six women.

Women are more vulnerable to psychological disorders, such as depression, a serious affective disorder whereby the prevailing emotional mood interferes with quality of life and normal functioning. **Postpartum depression** is specific to women and is diagnosed when a new mother develops a major depressive episode within one month after giving birth. Other psychological disorders include **eating disorders**, such as **anorexia nervosa** and bulimia, which are much more prevalent in teenage girls and young women than in boys and young men.

Other health issues affecting women include:

- Osteoporosis, or loss of the quantity of bone, common in postmenopausal women.
- Alcohol abuse, which can have adverse affects on fertility and in the developing fetus (fetal alcohol syndrome). Women frequently do not seek treatment because of fear of consequences (i.e., loss of child custody).
- Acquired immunodeficiency syndrome (AIDS), which represents the highest percent increase in the death rates of women.
- Violence is a major issue and a leading cause of death, primarily from a perpetrator who is or was a partner.

Demographics

A number of diseases affect women at a disproportionately high rate and the prevalence of some diseases is also increasing in women. For example, by the end of 2005, according to the World Health Organization (WHO), 17.5 million women worldwide were infected with HIV. According to the Centers for Disease Control and Prevention (CDC), between 2000 and 2004, the estimated number of **AIDS** cases in the United States increased 10% among women compared to 7% in males. In 2004, women accounted for 27% of the 44,615 newly reported AIDS cases among adults and adolescents. HIV affects African-American and Hispanic women to a higher degree. Even though they represent less than 25% of all women in the United States, they account for more than 79% of AIDS cases in women. Worldwide, more than 90% of all adolescent and adult HIV infections have resulted from heterosexual intercourse. Women are particularly vulnerable to heterosexual HIV transmission as a result of substantial mucosal exposure to seminal fluids. This increases the risk of HIV transmission when coupled with the high prevalence of non-consensual sex, sex without condom use, and the high-risk behaviors of their partners.

Heart disease also ranks high in women's health issues. It is responsible for more deaths in women than all forms of cancer combined. Heart disease is the most significant health concern for women in the United States, causing nearly 350,000 deaths each year.

The third leading cause of cancer death for women in the United States is colorectal cancer. Colorectal cancer is often mistakenly thought of as a man's disease, but equal numbers of men and women die of colorectal cancer each year.

Nearly 160,000 people in the United States die of stroke each year, and almost two-thirds of them are women. Stroke not only ranks as women's third killer, but is also one of the leading causes of women's disability in the United States.

Chronic lung conditions, including **bronchitis** and **emphysema**, kill approximately 65,000 women in the United States each year. The main cause is smoking, strongly associated with lung cancer.

More women than men have **Alzheimer's disease**. Some 45,000 women die with Alzheimer's disease each year, more than twice the number of men. One reason more women may be affected is that women generally live longer, and the risk of Alzheimer's increases with age.

Autoimmune diseases, which include **systemic lupus erythematosus** (SLE), **rheumatoid arthritis**, and **multiple sclerosis**, represent another health issue for women. Although many autoimmune diseases are rare, collectively these chronic diseases afflict 5–8% of the U.S. population and affect women at much higher rates. For example, 90% of the nearly two million Americans diagnosed with (or suspected of having) SLE are women.

Chronic fatigue syndrome (CFS) is another disorder that is diagnosed two to four times more often in women than in men.

An estimated 15 million new cases of **sexually transmitted diseases** (STD) occur in the United States each year. Some STDs such as **syphilis** have declined in women, while others (e.g., **genital herpes**, **gonorrhea**, chlamydia) continue to spread through the population, posing a significant health problem for women. This is because symptoms in women are minor or nonspecific, especially in the early stages. The result is that STDs in women sometimes are not diagnosed until late in the disease. STDs that occur during pregnancy can affect the fetus or newborn. About one-quarter to one-half of women infected with an STD during pregnancy give birth to either premature or low-birthweight infants. In about one-third to two-thirds of these pregnancies, the infection is passed to the infant, possibly causing permanent disabilities.

Psychological and affective disorders are more prevalent in women. Major depression and dysthymia affect twice as many women as men. This two-to-one ratio exists regardless of racial and ethnic background or economic status. The same ratio has been reported in ten other countries all over the world. Men and women have about the same rate of **bipolar disorder**, although its course in women typically has more depressive and fewer manic episodes. A greater number of women have the rapid cycling form of bipolar disorder, which may be more resistant to standard treatments. As for postpartum depression, it is estimated that 10–15% of women experience it after giving birth. As for eating disorders, the American Anorexia/Bulimia Association reports that more than 1,000 women and girls die of anorexia each year and more than 90% of people with anorexia are adolescent and young women.

Causes and symptoms

Cardiovascular disease can be caused by blockage of a blood vessel, high blood pressure, or a secondary complication to another disease. There may be an abnormal heart rhythm or cell death. Patients may complain of a broad spectrum of symptoms that may include **pain**, chest discomfort, high blood pressure, or strain during physical exertion.

When attempting to define the cause and symptoms of cancer, it is important to assess the type of cancer and location. Additionally, whether the tumor is localized (benign) or has spread to other areas (malignant) is vital for treatment planning and overall prognosis. In cases of breast cancer there may be a lump discovered during self-examination or **mammography** (special breast x rays).

Cerebrovascular disease may cause **tremors** (shaking), loss of balance and coordination, or functional and sensation loss in some parts of the body. Patients may have sudden transient strokes that could result in temporary loss of consciousness and **amnesia** of the incident. Patients may also develop chronic neurological states that causing **memory loss** and behavioral changes (Alzheimer's disease).

Patients with pulmonary (lung) cancer may develop **shortness of breath**, **fatigue**, weight loss, worsening **cough**, and coughing up bright red blood with sputum. Lung infections such as **pneumonia** may present with high **fever**, weakness, difficulty breathing, and abnormal breath sounds heard with a stethoscope during **physical examination**.

Diabetes is a syndrome with disordered metabolism and high blood sugar due to an abnormality in the chemical that regulates sugar levels. It is characterized by an increased thirst, urination, and chronic skin infections.

Osteoporosis may cause the bones to be brittle and weak. It is usually not detected until bones start to break.

An alcohol abuser will continue to drink despite negative repercussions. The person may not seek treatment to evade legal and/or child custody problems. The patient may hide alcohol, or confine drinking to specific times. The disease progresses to where there may be permanent liver damage, memory blackouts, and **malnutrition**.

Depression is characterized by a combination of symptoms that interfere with the ability to work, sleep, study, eat, and enjoy once-pleasurable activities.

Patients with AIDS may not have symptoms for years. When active disease occurs, patients typically develop recurrent infections that are the usual cause of death.

Domestic violence is usually associated with a perpetrator who is in a relationship with the affected

person. **Abuse** can be manifested by physical violence and/or homicide.

Diagnosis

Diagnosis can be accomplished with a history, physical examination, and specialized tests or procedures.

Tests

For cardiovascular disease, an electrocardiogram can determine the activity of the heart. Additional tests may include **echocardiography** (ultrasonic waves that generate an image), stress testing, and studies that require placing a catheter with a probe to examine the damage to heart tissue. Special tests may inject dyes to enhance visualization.

Cancer may be detected using specialized test called **tumor markers** and imaging studies such as MRI and CAT scans. Cerebrovascular disease can be detected with a complete neurological examination and specialized imaging technology. Diabetes is usually detected by a careful history, presence of risk factors (obesity), and blood analysis of glucose levels. Osteoporosis can be evaluated with specialized bone densitometry.

Alcohol abuse can be established by a bio-psychosocial assessment and standardized tests that screen for this disorder. Psychological evaluation (such as the **Minnesota Multiphasic Personality Inventory**, MMPI) can usually detect depression or eating disorders. AIDS can be established by a careful history, belonging to high-risk groups and Western blot analysis (examination of blood to detect the protein of human **immunodeficiency** virus). Violence can be established by physical signs of beating, such as cuts and **bruises**.

Treatment

Treatment depends on the extent of disease and the present health status of the patient. In some cases, treatment may stopped or it may altogether be refused.

Treatment for cardiovascular disease may include surgical intervention and/or conservative medical treatment with medications. Diet, **exercise**, and weight reduction are important parameters for treatment planning. Appropriate referrals, counseling, and follow-up are usually indicated. Treatment for cancer may include a combination of surgery, **chemotherapy**, or **radiation therapy**. These treatment modalities may be given singly or in combination different times during disease progression. Cerebrovascular disease can be treated surgically and/or with medications that thin the blood. Symptomatic care may be indicated in addition to close monitoring if the patient develops disability and/or cognitive impairment.

Diabetes can be treated by dietary modifications and medications, which treat abnormal levels of blood glucose (sugar). Osteoporosis can be treated with estrogen replacement therapy and regular vitamin/mineral intake. Alcohol abuse may require long-term therapy, inpatient treatment and medications. Community-centered support group meetings are also recommended as a form of treatment maintenance.

To date there is no treatment for AIDS, other than medications that offer symptomatic relief. Alcohol abuse, psychological disorders, and violence require therapy, possible medication, and community centered support group meetings.

Alternative

There are numerous studies that support intake of co-enzyme Q10 for cardiovascular health. Studies have shown that beta-carotene and vitamin E and C have no effect for cancer. Some studies indicate positive results for reproductive health using **acupuncture**. Certain herbs may be beneficial during menopause. According to most medical literature, further research using scientific method is vital for general acceptance.

Clinical trials

Many clinical trials for the study and treatment of women's health are currently sponsored by the National Institutes of Health (NIH) and other agencies. Clinical trial information is constantly updated by NIH.

Prognosis

The prognosis depends on the extent of disease and the physical and emotional status of the patient. Prognosis is also related to tolerance of treatment, adverse drug effects, complication during or after surgery, disease resurgence, and patient compliance with treatment recommendations.

Prevention

One of the most reliable measures of prevention is education and training. The Council on Graduate Medical Education and several institutes of the NIH have provided funding for numerous centers to research women's health issues. On a more individual level, preventive and personal habits are vital for good

KEY TERMS

Alzheimer's disease—A progressive neurologic disease of the brain that leads to the irreversible loss of neurons and dementia.

Anorexia nervosa—Starving oneself to reduce body weight below the minimum level required to maintain health.

Antidepressant—A drug used to treat depression.

Bulimia—Eating excessively large amounts of food followed by vomiting or other forms of purging and stomach emptying.

Cardiovascular disease—A structural or functional abnormality of the heart, or of the blood vessels supplying the heart, that impairs its normal function.

Cerebrovascular disease—Disorders affecting the blood vessels that supply the brain that may result in a stroke.

Chlamydia—Small pathogens associated with pneumonia, abortion, diarrhea, conjunctivitis, arthritis, and encephalitis.

Dysthymia—Type of affective disorder or mood disorder that often resembles a less severe, yet more chronic form of major.

Electrocardiogram—An instrument that monitors heart rate and rhythm.

Emphysema—A chronic, irreversible disease of the lungs.

Estrogen—A hormone secreted by the ovaries that affects many aspects of the female body, including a woman's menstrual cycle and normal sexual and reproductive development.

Estrogen replacement therapy—Use of the female hormone estrogen to replace that which the body no longer produces naturally after medical or surgical menopause.

Genital herpes—A sexually-transmitted disease caused by the herpes simplex virus.

Gonorrhea—A sexually-transmitted infection caused by the bacterium *Neisseria gonorrhoea*.

Menopause—The time of life when a woman's menstrual periods stop. A woman is in menopause when she has not had a period for 12 months in a row.

Osteoporosis—A decrease in bone density.

Postmenopausal—A term referring to the time period following menopause.

Stroke—The sudden death of some brain cells due to a lack of oxygen when the blood flow to the brain is impaired by blockage or rupture of an artery to the brain.

Syphilis—A sexually-transmitted disease caused by the bacterium *Treponema pallidum*.

health. Most physicians believe that a baseline physical examination is a reliable comparative tool. Women should receive counseling for special health issues such as smoking, exercise, diet, primary disease prevention, safe sexual practices, alcohol abuse, psychological disorders, and violence. Knowledge of family history is important since many diseases have a strong propensity among first-degree relatives. Blood pressure should normally be measured every other year. Screening tests for breast, cervical, and colorectal cancer is recommended. Pap smears taken during routine pelvic examinations can screen for disease processes in the reproductive tract. Serum cholesterol monitoring and reduction are advised. Patients may require postmenopausal estrogen replacement therapy and vitamin/mineral supplements.

Wound culture

Definition

A wound culture is a laboratory test in which microorganisms from a wound are grown in a special growth medium. It is done to find and identify the microorganism causing an infection in a wound or an **abscess**. If a microorganism is found, more testing is done to determine how to treat the infection.

Purpose

Wounds are injuries to body tissues caused by disease processes or events such as **burns**, punctures, and human or animal **bites**. Wounds or abscesses also occur within body tissues as a result of surgery or dental procedures. Wounds become infected when microorganisms from the outside environment, or from within the person's body, enter the open wound and multiply. A wound that is red, painful, swollen, and draining pus is probably infected. A **fever** following surgery indicates an infection at the site of surgery.

To enable healing and prevent the spread of infection to other body tissues, the infecting microorganisms must be killed. A wound culture discovers which type of microorganism is causing the infection and the best antibiotic with which to kill it. This is important as physicians have become less inclined to prescribe **antibiotics** until certain they are needed because of antibiotic resistance that has developed due to overuse of the drugs.

KEY TERMS

Aerobe—Bacteria that require oxygen to live.

Anaerobe—Bacteria that live only where there is no oxygen.

Normal flora—The mixture of bacteria normally found at specific body sites.

Description

A sample of material, such as pus or a portion of tissue, is taken from the wound, placed in a sterile container, and sent to the laboratory. In the laboratory, this material is spread over the surface of several different types of culture plates and placed in an incubator at body temperature for one to two days.

A Gram stain is done by staining the slide with purple and red stains, then examining it under a microscope. If many white blood cells and bacteria are seen, it is an early confirmation of infection. The color of stain retained by the bacteria (purple or red), their shape (such as round or rectangular), and their size provides valuable clues as to their identity, and helps the physician predict which antibiotics might work best even before the entire test is completed. Bacteria that stain purple are called gram-positive; those that stain red are called gram-negative.

Bacteria can be grouped into two categories: aerobes and anaerobes. Aerobes are bacteria that need oxygen to live; anaerobes live only where there is no oxygen. Deep wounds, closed-off from oxygen, are an ideal environment for an anaerobic infection to develop. Foul-smelling odor, gas, or **gangrene** at the infection site are signs of an infection caused by an anaerobic bacteria. Routine cultures typically only look for aerobic bacteria. If the physician tells the laboratory to include a culture for anaerobes, a portion of the wound sample will be put on culture plates, or in a tube of culture broth, and incubated in a special chamber without oxygen.

Bacteria present in the wound sample will multiply and appear as visible colonies on the plates, or as cloudiness in the tube of broth. They are identified by the appearance of their colonies, the results of biochemical tests, and information from Gram staining part of the bacterial colony.

A sensitivity test, also called an antibiotic susceptibility test, is also done. The bacteria are tested against different antibiotics to determine which will treat the infection by killing the bacteria.

If the physician thinks the wound may be infected with a mold or yeast, a fungal culture is also done. The wound sample is spread on special culture plates that are treated to encourage the growth of mold and yeast. Different biochemical tests and stains are used to identify molds and yeast.

Other more unusual microorganisms, such as *Mycobacterium leprae*, may be the cause of a wound infection. The physician must notify the laboratory to culture specifically for these more unusual microorganisms.

The initial Gram stain result is available the same day, or in less than an hour if requested by the physician. An early report, known as a preliminary report, is usually available after one day. This report will tell if any microorganisms have yet been found, and, if so, their Gram stain appearance. For example, they may have the appearance of a gram-negative rod, or a gram-positive cocci (spherical shape). The final report, usually available in one to three days, includes complete identification, an estimate of the quantity of the microorganisms, plus a list of the antibiotics to which they are sensitive. Cultures for fungi and anaerobic bacteria may take two to three weeks.

Wound culture is also called soft tissue culture, abscess culture, or wound culture and sensitivity.

Preparation

A piece of the infected tissue is the best specimen. If this is not possible, the next best specimen is pus from the wound. Because many microorganisms normally live on skin and mucous membrane, the specimen must not be allowed to touch the area surrounding the wound.

The physician first cleans the surface of the wound using alcohol. Using a syringe, the physician suctions out (aspirates) as much pus as possible from the wound. Next, this is sent to the laboratory in a sterile container. If it is impossible to aspirate the pus, pus from within the wound can be collected on a swab.

The physician may choose to start the person on an antibiotic before the culture and sensitivity tests are completed. However, the specimen for culture should be collected before antibiotics are begun. Antibiotics in the person's system may prevent microorganisms present in the wound from growing in culture, and thus not be identifiable.

Normal results

A normal culture may be contaminated by a mixture of microorganisms normally found on a person's skin (normal flora).

It is not uncommon for the microorganism causing a wound infection to not grow in culture. This is particularly true if the specimen was collected with a swab rather than an aspirate or tissue biopsy.

Abnormal results

Streptococcus Group A, ***Escherichia coli***, *Proteus*, *Klebsiella*, *Pseudomonas*, *Enterobacter*, Enterococci, *Staphylococcus aureus*, *Bacterioides*, and *Clostridium*, are common causes of wound infections. More than one microorganism may be the cause of the infection.

Wound flushing

Definition

Wound flushing is a method of cleaning a wound by applying pressurized water or antiseptic solutions to the tissues. It is also called irrigation.

Purpose

Wound flushing is used to help flush debris from a wound, lessening the risk of infection or treating an infection that already exists. If the wound is flushed with an antiseptic, it is more likely to heal correctly; flushing the wound can help prevent the surface from healing over a possibly infected area underneath.

Wound flushing is routinely performed by dentists or oral surgeons following tooth extractions, mouth trauma, or gum surgery, to prevent bacteria from the mouth entering the bloodstream as well as to cleanse the tooth socket.

KEY TERMS

Antiseptic—Chemicals applied to the skin to destroy bacteria and prevent infection.

Irrigation—The medical name for wound flushing.

Description

Wound flushing is usually done in a hospital or oral surgery center, although if it is performed at home, there is less chance of infection because of the higher risk of bacterial contamination in the hospital environment. Wound flushing is especially helpful in treating people with **bites**, lacerations, or crush injuries, which often become infected due to the presence of dead tissue and foreign debris, such as splinters or dirt. In a non-surgical situation, the procedure is usually performed by a nurse. An acute injury, such as a crushing wound or knife cut, the wound is flushed right before the injury is stitched closed. For people with chronic **wounds**, such as bed sores or abscesses, the wound may be flushed periodically to treat or prevent infection. During an operation, a surgeon uses an antibacterial solution to flush the surgical site just before stitching the wound closed. After surgery, the wounds may be flushed to treat or prevent infection.

Preparation

The nurse or doctor may inject the site with a local anesthetic before flushing the wound.

Aftercare

After the wound is flushed, the health care provider cleans the area around the wound to guard against infection. Packing to absorb excess fluids may be placed into the wound, followed by a sterile bandage.

Risks

Complications rarely occur, especially if the solution used to flush the wound is chosen carefully so as to avoid skin irritation; occasionally, however, serious infections are reported. In addition, damage to skin or internal organs has been reported from the use of hydrogen peroxide to flush wounds or irrigate the abdominal cavity after surgery.

Patients should call the doctor immediately if there is any sign of infection, such as **fever**, pus, or swelling.

Normal results

The wound will heal correctly, from the inside out, without infection.

Wounds

Definition

A wound occurs when the integrity of any tissue is compromised (e.g. skin breaks, muscle tears, **burns**, or bone **fractures**). A wound may be caused by an act, such as a gunshot, fall, or surgical procedure; by an **infectious disease**; or by an underlying condition.

Demographics

Wounds are very common. Nearly everyone has had a wound of one type or another. Minor wounds are especially common in childhood because children engage in so much play and activity. Annually, about 3.6 million Americans acquire some type of open wound requiring treatment by a healthcare provider, and an additional four million Americans are affected by a chronic wound.

Description

Types and causes of wounds are wide ranging, and health care professionals have several different ways of classifying them. They may be chronic, such as the skin ulcers caused by **diabetes mellitus**, or acute, such as a gunshot wound or animal bite. Wounds may also be referred to as open, in which the skin has been compromised and underlying tissues are exposed, or closed, in which the skin has not been compromised, but trauma to underlying structures has occurred (e.g. a bruised rib or cerebral contusion). Emergency personnel and first-aid workers generally place acute wounds in one of eight categories:

- Abrasions. Also called scrapes, they occur when the skin is rubbed away by friction against another rough surface (e.g. rope burns and skinned knees).
- Avulsions. These occur when an entire structure or part of it is forcibly pulled away, such as the loss of a permanent tooth or an ear lobe. Explosions, gunshots, and animal bites may cause avulsions.
- Contusions. Also called bruises, these are the result of a forceful trauma that injures an internal structure without breaking the skin. Blows to the chest, abdomen, or head with a blunt instrument (e.g., a football or a fist) can cause contusions.
- Crush wounds. Occur when a heavy object falls onto a person, splitting the skin and shattering or tearing underlying structures.
- Cuts. These are slicing wounds made with a sharp instrument, leaving even edges. They may be as minimal as a paper cut or as significant as a surgical incision.
- Lacerations. Also called tears, these are separating wounds that produce ragged edges. They are produced by a tremendous force against the body, either from an internal source as in childbirth, or from an external source like a punch.
- Missile wounds. Also called velocity wounds, they are caused by an object entering the body at a high speed, typically a bullet.

Examples of open wounds. *(Illustration by Electronic Illustrators Group. Reproduced by permission of Gale, a part of Cengage Learning.)*

- Punctures. These are deep, narrow wounds produced by sharp objects such as nails, knives, and broken glass.

Causes and symptoms

Acute wounds have a wide range of causes. Often they are the unintentional results of motor vehicle accidents, falls, mishandling of sharp objects, or sports-related injury. Wounds may also be an intentional result of violence involving assault with weapons, including fists, knives, or guns.

The general symptoms of a wound are localized **pain** and bleeding. Specific symptoms include:

- An abrasion usually appears as lines of scraped skin with tiny spots of bleeding.
- An avulsion has heavy, rapid bleeding and a noticeable absence of tissue.
- A contusion may appear as a bruise beneath the skin or may appear only on imaging tests. An internal wound may also generate symptoms such as weakness, perspiration, and pain.
- A crush wound may have irregular margins like a laceration; however, the wound will be deeper and trauma to muscle and bone may be apparent.
- A cut may have little or profuse bleeding depending on its depth and length; its even edges readily line up.
- A laceration may have little or profuse bleeding. The tissue damage is generally greater and the wound's ragged edges do not readily line up.
- A missile entry wound may be accompanied by an exit wound, and bleeding may be profuse, depending on the nature of the injury.
- A puncture wound will be greater in depth than in its length, therefore there is usually little bleeding around the outside of the wound and more bleeding inside, causing discoloration.

Diagnosis

A diagnosis is made by visual examination and may be confirmed by a report of the causal events. Medical personnel will also assess the extent of the wound and the effect it has had on the patient's well-being (e.g., profound blood loss, damage to the nervous system or skeletal system).

Treatment

Treatment of wounds involves stopping any bleeding, then cleaning and dressing the wound to prevent infection. Additional medical attention may be required if the effects of the wound have compromised the body's ability to function effectively.

Stopping the bleeding

Most bleeding may be stopped by direct pressure. Direct pressure is applied by placing a clean cloth or dressing over the wound and pressing the palm of the hand over the entire area. This limits local bleeding without disrupting a significant portion of the circulation. The cloth absorbs blood and allows clot formation. The clot should not be disturbed, so if blood soaks through the cloth, another cloth should be placed directly on top rather than replacing the original cloth.

If the wound is on an arm or leg that does not appear to have a broken bone, the wound should be elevated to a height above the person's heart while direct pressure is applied. Elevating the wound allows gravity to slow down the flow of blood to that area.

If severe bleeding cannot be stopped by direct pressure or with elevation, the next step is to apply pressure to the major artery supplying blood to the area of the wound. In the arm, pressure would be applied to the brachial artery by pressing the inside

KEY TERMS

Abrasion—Also called a scrape. The rubbing away of the skin surface by friction against another rough surface.

Avulsion—The forcible separation of a piece of tissue from an entire structure.

Butterfly bandage—A narrow strip of adhesive with wider flaring ends (shaped like butterfly wings) used to hold the edges of a wound together while it heals.

Cut—Separation of skin or other tissue made by a sharp edge, producing regular edges.

Laceration—Also called a tear. Separation of skin or other tissue by a tremendous force, producing irregular edges.

Plasma—The straw-colored fluid component of blood, without blood cells.

Puncture—An injury caused by a sharp, narrow object deeply penetrating the skin.

Tourniquet—A device used to control bleeding, consisting of a constricting band applied tightly around a limb above the wound. It should only be used if the bleeding in life-threatening and can not be controlled by other means.

Traumatic shock—A condition of depressed body functions as a reaction to injury with loss of body fluids or lack of oxygen. Signs of traumatic shock include weak and rapid pulse; shallow and rapid breathing; and pale, cool, clammy skin.

Whole blood—Blood that contains red blood cells, white blood cells, and platelets in plasma.

of the upper arm against the bone. In the leg, pressure would be applied to the femoral artery by pressing on the inner crease of the groin against the pelvic bone.

If the bleeding from an arm or leg is so extreme as to be life-threatening and if it cannot be stopped by any other means, a tourniquet may be required. However, in the process of limiting further blood loss, the tourniquet also drastically deprives the limb tissues of oxygen. As a result, the patient may live but the limb may die.

In 2004, a new solution to stopping bleeding was introduced. Called QuikClot, the U.S. Food and Drug Administration (FDA) approved substance is made up of synthetically made material called zeolite, which occurs naturally in volcanic rock. When used properly, it can be poured into a wound that will not stop bleeding and will slow blood loss. The trauma pack costs about 50 cents and has shown particular promise in the battlefield and in wilderness situations.

Dressing the wound

Once bleeding has been stopped, cleaning and dressing the wound is important for preventing infection. Although flowing blood flushes debris from the wound, running water should also be used to rinse away dirt. Embedded particles such as wood slivers and glass splinters, if not too deep, may be removed with a needle or pair of tweezers that has been sterilized in rubbing alcohol or in the heat of a flame. Once the wound has been cleared of foreign material and washed, it should be gently blotted dry, with care not to disturb the blood clot. An antibiotic ointment may be applied. The wound should then be covered with a clean dressing and bandaged to hold the dressing in place.

Getting medical assistance

A person who has become impaled on a fixed object, such as a fence post or a stake in the ground, should be moved only by emergency medical personnel. **Foreign objects** embedded in the eye should be removed only by a doctor. Larger penetrating objects, such as a fishhook or an arrow, should be removed only by a doctor to prevent further damage as the object exits the body.

Additional medical attention is necessary in several instances. Wounds that penetrate the muscle beneath the skin should be cleaned and treated by a doctor. Such a wound may require sutures (stitches) to keep it closed during healing. Some deep wounds that do not extend to the underlying muscle may only require butterfly **bandages** to keep them closed during healing. Wounds to the face and neck, even small ones, should always be examined and treated by a doctor to preserve sensory function and minimize scarring. Deep wounds to the hands and wrists should be examined for nerve and tendon damage. Puncture wounds may require a **tetanus** shot to prevent serious infection. Animal **bites** should always be examined and the possibility of **rabies** infection determined.

Infection

Wounds that develop signs of infection should also be brought to a doctor's attention. Signs of infection are swelling, redness, tenderness, throbbing pain, localized warmth, **fever**, swollen lymph glands, the presence of pus either in the wound or draining from it, and red streaks spreading away from the wound.

Emergency treatment

With even as little as one quart of blood lost, a person may lose consciousness and go into traumatic **shock**. Because this is a life-threatening situation, emergency medical assistance should be called immediately. If the person stops breathing, artificial respiration (also called mouth-to-mouth resuscitation or rescue breathing) should be administered. In the absence of a pulse, **cardiopulmonary resuscitation** (CPR) must be performed. Once the person is breathing unassisted, the bleeding may be attended to.

In cases of severe blood loss, medical treatment may include the intravenous replacement of body fluids. This may be infusion with saline or plasma, or a **transfusion** of whole blood.

Chronic wound treatment

Treating a chronic wound involves encouraging an environment in the wound bed that promotes healing, supporting overall health and **nutrition**, and managing chronic conditions (such as diabetes) that contribute to chronic wounds. **Debridement** of dead tissue from the wound, either by surgery or with the use of enzymatic debriding medication, helps create a wound bed that enables new tissue granulation. Occlusive moist **dressings** encourage autolytic debridement, which is the body's own sloughing and breaking down of dead cells. Negative pressure dressings, silver-containing antimocrobial medication, hyperbaric **oxygen therapy**, **physical therapy**, and **nutritional supplements** are also available to treat chronic wounds. Chronic wounds are often chronically painful, so **pain management** is important to enable the affected person to participate fully in their care and maintain their usual activities.

In some cases, clinicians have resorted to a Civil War-era treatment that does not sound appealing, but works well enough to receive FDA approval. Maggots can be placed on wounds that refuse to heal with high–tech medical methods. The maggots are dropped into the wound and covered with special mesh to keep them in place. They are removed in two to three days.

Alternative treatment

In addition to the conventional treatments described above, there are alternative therapies that may help support the injured person. Homeopathy can be very effective in acute wound situations. *Ledum* (*Ledum palustre*) is recommended for puncture wounds (taken internally). Calendula (*Calendula officinalis*) is the primary homeopathic remedy for wounds. An antiseptic, it is used topically as a succus (juice), tea, or salve. Another naturally occurring antiseptic is tea tree oil (*Melaleuca* spp.), which can be mixed with water for cleaning wounds. Aloe (*Aloe barbadensis*) can be applied topically to soothe skin during healing. When wounds affect the nerves, especially in the arms and legs, St. John's wort (*Hypericum perforatum*) can be helpful when taken internally or applied topically. **Acupuncture** can help support the healing process by restoring the energy flow in the meridians that have been affected by the wound. Alternative treatments should be used with care, as the benefits of many such treatments have not been confirmed by scientific research.

Prognosis

Without the complications of infection or excess blood loss, most wounds heal well with time. Depending on the depth and size of the wound, it may or may not leave a visible scar.

Generally, wounds heal in a series of progressive steps. During the inflammatory phase, which begins with the injury, blood vessels narrow and clot formation begins. Substances are also released that initiate the healing process and macrophages begin to clear the wound of debris. The next phase is one of proliferation, during which a network of collagen and new capillaries begin to form the basis of the healing wound bed. The wound appears dark pink or purple due to the presence of many new capillaries that supply blood to the healing tissue. During the phase of epithelialization, new skin cells begin to form, eventually creating a new barrier between the wound bed and outside elements. This process usually begins within about 48 hours of injury. The collagen and new skin cells become more organized during the remodeling phase, which ends in the closure of the wound with skin that is about 75% as strong as the original skin. When excess collagen is formed in a wound bed that penetrates the dermis, a scar is formed. When wound healing is severely delayed or remains in a particular phase, it becomes a chronic wound.

Prevention

Most actions that result in wounds are preventable. Injuries from motor vehicle accidents may be reduced by wearing seat belts and placing children in size-appropriate car seats in the back seat. Sharp, jagged, or pointed objects or machinery parts should be used according to the manufacturer's instructions and only for their intended purpose. Firearms and

explosives should be used only by adults with explicit training; they should also be kept locked and away from children. Persons engaging in sports, games, and recreational activities should wear all proper protective equipment and follow safety rules.

Chronic wounds are best avoided by preventing the diseases that cause them. Diabetes and **peripheral vascular disease** are the major causes of chronic wounds among ambulatory people. Maintaining a healthy diet, weight, and lifestyle that includes **exercise** are helpful in preventing either of these conditions. Maintaining control of blood glucose levels, along with care of the feet and toes is important for persons with diabetes in preventing wounds that can become chronic. In non-ambulatory persons, pressure reliving devices in wheelchairs or beds, frequent changes in position, and sometimes **diets** fortified with protein, **vitamins** A and C, and the mineral zinc can help prevent chronic ulcerating wounds.

X

X-linked agammaglobulinemia

Definition

X-linked agammaglobulinemia (XLA), or Bruton's agammaglobulinemia, is present at birth (congenital) and is characterized by low or completely absent levels of immunoglobulins in the bloodstream. Immunoglobulins are protein molecules in blood serum that function like antibodies. Without them, the body lacks a fully functioning immune system. Persons with XLA are vulnerable to repeated, potentially fatal bacterial infections.

Description

XLA occurs in one in 50,000 to one in 100,000 newborns. Almost all persons with the disorder are males. Although persons with XLA carry the genes to produce immunoglobulins, a genetic defect on the X chromosome prevents their formation. This defect is not associated with the immunoglobulins themselves, but rather with the B cells in the bloodstream that ordinarily secrete the immunoglobulins.

B cells are a type of white blood cell. They are the sole producers of immunoglobulins in the body. B cells are produced in the bone marrow and carried to the spleen, lymph nodes, and other organs as they mature. The maturation process depends on an enzyme called Bruton's agammaglobulinemia tyrosine kinase (Btk). If Btk is missing or defective, the B cells cannot mature and cannot produce immunoglobulins.

The gene for Btk is on the X chromosome. Certain changes (mutations) in this gene result in defective Btk. Since the gene is carried on the X chromosome, XLA individuals are almost always male. Females have two X chromosomes, which means they have two copies of the Btk gene, one of which is normal. Males have only one X chromosome.

Causes and symptoms

XLA is caused by a defect in the gene that codes for Btk. This defect leads to blocked maturation of B cells, the cells that produce immunoglobulins. Because other portions of the immune system are functional, people with XLA can fight off some types of infection, such as fungal and most viral infections. Immunoglobulins, however, are vital to combat bacterial infections. Infants with XLA usually do not show symptoms during the first six months of life because immunoglobulins from their mothers are circulating in their bloodstreams. As the mother's supply decreases, the baby becomes increasingly vulnerable to bacterial infections.

Common symptoms of immunoglobulin deficiency appear after the infant is six months old. They include frequent ear and sinus infections, **pneumonia**, and **gastroenteritis**. Certain viruses, such as hepatitis and **polio**, can also pose a threat. Children with XLA grow slowly, have small tonsils and lymph nodes, and may develop chronic skin infections. Approximately 20% of these children develop arthritis, possibly as a result of joint infections.

Diagnosis

Frequent bacterial infections, a lack of mature B cells, and low-to-nonexistent levels of immunoglobulins point to a diagnosis of XLA. A sample of the infant's blood serum can be analyzed for the presence of immunoglobulins by a technique called **immunoelectrophoresis**. To make a definitive diagnosis, the child's X chromosome is analyzed for defects in the Btk gene. Similar analysis can be used for prenatal diagnosis or to detect carriers of the defective gene.

Treatment

Treatment of XLA consists of regular intravenous doses of commercially prepared **gamma globulin** (sold under the trade names Gamimune or Gammagard) to ward off infections. **Antibiotics** are used to treat

KEY TERMS

Antibody—A molecule that is produced by the immune system in response to a protein, called an antigen, that is not recognized as belonging in the body.

B cell—A type of lymphocyte, or white blood cell, that is a key component of the body's immune system. Mature B cells produce immunoglobulins.

Bruton's agammaglobulinemia tyrosine kinase (Btk)—An enzyme vital for the maturation of B cells.

Carrier—A person who has a genetic defect but does not develop any symptoms or signs of the defect. The carrier's offspring may inherit the defect and develop the associated disorder.

Enzyme—A protein molecule that prompts rapid biochemical reactions.

Immunoglobulin—A protein molecule formed by mature B cells in response to foreign proteins in the body. There are five types of immunoglobulins, but the major one is gamma globulin, or immunoglobulin G.

Mutation—A change in a gene that alters the function or other characteristics of the gene's product.

X chromosome—One of the two sex chromosomes (the other is Y) that determine a person's gender. Normal males have both an X and a Y chromosome, and normal females have two X chromosomes.

infections as they occur. Children with XLA must be treated promptly for even minor cuts and scrapes and taught to avoid crowds and people with active infections.

Prognosis

Prior to the era of gamma globulin and antibiotic treatment, approximately 90% of XLA individuals died before age 8. Early diagnosis and current therapy allows most individuals with XLA to reach adulthood and lead relatively normal lives. Infants who develop polio or persistent viral infections, however, have a poorer prognosis.

Prevention

Parents of a child with XLA should consider **genetic counseling** if they are planning to have more children.

Julia Barrett

X rays of the orbit

Definition

Orbital x rays are studies of the area and structures containing the eye. The orbit is the circle of thin bones that houses and protects the eye, even extending behind the eye and nearly wrapping around it. The orbit includes the eyebrow, the bridge of the nose and the cheekbone. X rays are a form of radiation (like light) that can penetrate body tissues.

Purpose

Orbital x ray, or orbital radiography, is often used to detect problems resulting from injury or trauma to the eye. The exam may also detect changes to the structure of the eye, which may indicate various diseases. An ophthalmologist may also order an orbital x ray if there is concern that foreign bodies may be present in the eye that cannot be detected with an instrument called an ophthalmoscope.

Precautions

Pregnant women and women who could possibly be pregnant should only receive orbital x rays when absolutely necessary. If the patient is in severe **pain** due to injury or trauma, a painkiller may be given to help ease discomfort during positioning of the head throughout the exam. No other precautions are necessary for orbital x rays.

Description

Each orbit is composed of a floor, a roof, a medial (in the center plane) and lateral (sides of the plane) walls. The orbital x ray involves several different views in order for the physician to clearly see various parts of the eye without obstruction. In orbital x rays, images of the unaffected eye may also be taken to compare its shapes and structures to those of the affected eye. Views may include side view (lateral), back to front (posteroanterior), base view, views from both sides, and an image from the center to one outside edge (half-axial projection). Projections of the optical canal will also be included. For all of these views, the patient may be seated upright or asked to lie on a table in the x ray room.

The orbital x ray procedure should take about 15 minutes to complete. Following the procedure, the patient will usually be asked to wait until the films are developed to ensure they are high enough quality and that repeat x rays are not necessary. A physician may perform the x ray exam in his or her office, or refer the patient to an outpatient radiology facility or hospital radiology department. In the case of emergency, the exam may be performed in the emergency room or a nearby radiology area of the hospital.

Preparation

There are no special dietary preparations needed prior to an orbital x ray. As with any radiography procedure, the patient should remove any jewelry or metal objects, which may interfere with a clear image.

Aftercare

No aftercare is required following this diagnostic test.

Risks

Radiation exposure is low for this procedure and all certified radiology facilities follow strict personnel and equipment guidelines for radiation protection. Women of child bearing age and children should be offered protective shielding (lead aprons) to cover the genital and/or abdominal areas.

Normal results

Normal findings will show the bones of the orbit intact, and will show similarity between the orbit that is being studied and the unaffected orbit.

Abnormal results

Positive findings from an orbital x ray may show that there has been injury to the eye. Certains signs may indicate some disease that is affecting the orbital structures. Tiny **fractures** in the orbital bones can usually be detected on the radiograph. The floor bone, the medial wall and the ethmoid bone, which is a spongy bone that forms the upper part of the nasal cavity, are the most likely to break. In a blowout fracture (one involving the orbital floor), radiographic findings may include disruption to the orbital floor, an opaque look to the sinuses on the same side as the affected orbit (due to hemorrhage), or signs of sinus problems from the orbital root's interference. These indications can be seen in most typical orbital x ray views.

Since the physician examines both orbits side by side, indications of differences in size and shape of the various structures in the orbit may be apparent. The orbit may be enlarged, indicating irritation from an injury or foreign body. A number of growing tumors within the eye or brain area may also cause orbital enlargement. Destruction of the walls of the orbit may indicate a nearby infection or malignancy. Changes in density of the tiny orbit bones may also be a sign of bone disease or **cancer** spread to bone.

Children's orbits are more likely to be enlarged by a fast growing lesion, since their orbital bones have not fully developed.

KEY TERMS

Blowout fracture—A fracture or break in the orbit that is caused by sudden and violent impact to the area.

Malignancy—A tumor that is cancerous and growing.

Medial wall—The middle bone, or wall, of the eye's orbit. It is generally thicker than the roof and floor walls.

Ophthalmologist—A physician who specializes in the workings, structures, and care of the eyes.

Ophthalmoscope—An instrument routinely used by ophthalmologists to examine the interior of the eye. It consists of a small light, a mirror, and lenses of differing powers that magnify.

Radiography—Examination of any part of the body through the use of x rays. The process produces an image of shadows and contrasts on film.

X ray—A form of electromagnetic radiation with shorter wavelengths than normal light. X rays can penetrate most structures.

Y

Yaws

Definition

Yaws is a chronic illness that first affects the skin and then affects the bones.

Description

Yaws tends to strike children, particularly between the ages of two and five. It is common in areas where poverty and overcrowding interfere with good hygiene practices. The most common locations are in rural areas throughout Africa, Southeast Asia, and in locations bordering the equator in the Americas.

Causes and symptoms

Yaws is caused by a spiral-shaped bacterium (spirochete) called *Treponema pertenue*. This bacterium belongs to the same family as the bacterium that causes **syphilis**.

Yaws is passed among people by direct skin contact. It requires some kind of a scratched or insect bitten area in order for the bacteria to actually settle in and cause infection. An injured spot on the leg is the most common part of the body through which the bacteria enter. Young children, who are constantly bumping themselves in play, who wear little clothing, who do not wash their hands often, and who may frequently put their hands in their mouths, are particularly susceptible.

The first symptom of yaws occurs three to four weeks after acquiring the bacteria. The area where the bacteria originally entered the skin becomes a noticeable bump (papule). The papule grows larger and develops a punched-out center (ulcer), covered with a yellow crust. Lymph nodes in the area may become swollen and tender. This first papule may take as long as six months to heal. Secondary soft, gummy growths then appear on the face, arms and legs, and buttocks. These soft, tumor-like masses may grow on the soles of the feet, causing the patient to walk in an odd and characteristic fashion on the sides of his or her feet (nicknamed "crab yaws"). More destructive tumors may then disrupt the bones of the face, the jaw, and the lower leg. Ulcers around the nose and on the face may be very mutilating.

Diagnosis

Samples taken from the first papules may be examined using a technique called dark-field microscopy. This often allows the spirochetes to be identified. They may also be identified in fluid withdrawn from swollen lymph nodes. Various tests can also be run on blood samples to determine if an individual is producing antibodies (special immune cells) which are specifically made in response to the presence of these spirochetes.

Treatment

A single penicillin injection in a muscle is sufficient to completely end the disease.

Prognosis

Without treatment, yaws is a terribly disfiguring, chronic illness. With appropriate treatment, the progression of the disease can be completely halted.

Prevention

For a time, the World Health Organization (WHO) was working to totally eradicate yaws, just as **smallpox** was successfully eradicated. This has not occurred, however. WHO continues to work to identify and respond to outbreaks quickly, in an effort to at least slow the spread of yaws.

KEY TERMS

Papule—A raised bump on the skin.

Ulcer—A punched-out, irritated pit on the skin.

Yellow fever

Definition

Yellow **fever**, also known as sylvatic fever and viral hemorrhagic fever or VHF, is a severe **infectious disease** caused by a type of virus called a flavivirus. This flavivirus can cause outbreaks of epidemic proportions throughout Africa and tropical America.

Demographics

Yellow fever is found most commonly in men between the ages of 15 and 45 years who work outdoors and live in fever-endemic areas. Race has not been shown to be a factor in contraction or transmission. Between 1970 and 2002, only nine cases of yellow fever were reported in travelers from the United States and Europe. All cases were found in unimmunized travelers who had visited South America or Africa. Seven of the cases were fatal.

Description

The first written evidence of a yellow fever epidemic occurred in the Yucatan in 1648. Since that time, much has been learned about the interesting transmission patterns of this devastating illness. It is thought that the disease originated in Africa and spread to the Americas in the seventeenth and eighteenth centuries through trading ships. The flavivirus that causes yellow fever was first identified in 1928 and the first vaccine against the disease was produced at the Rockefeller Institute in New York in 1937.

In order to understand how yellow fever is passed, several terms need to be defined. The word "host" refers to an animal that can be infected with a particular disease. The term "vector" refers to an organism that can carry a particular disease-causing agent (such as a virus or bacteria) without actually developing the disease. The vector can then pass the virus or bacterium on to a new host.

Many of the common illnesses in the United States (including the **common cold**, many viral causes of **diarrhea**, and **influenza** or "flu") are spread by direct passage of the causative virus between human beings. Yellow fever, however, cannot be passed directly from one infected human to another. Instead, the virus responsible for yellow fever requires an intermediate vector, a mosquito, which carries the virus from one host to another.

The hosts of yellow fever include both humans and monkeys. The cycle of yellow fever transmission occurs as follows: an infected monkey is bitten by a tree-hole breeding mosquito. This mosquito acquires the virus and can pass the virus on to any number of other monkeys that it may bite. This form of yellow fever is known as sylvatic yellow fever, and usually affects humans only incidentally. When a human is bitten by an infected mosquito, the human may acquire the virus. In the case of South American yellow fever, the infected human may return to the city, where an urban mosquito (*Aedes aegypti*) serves as a viral vector, spreading the infection rapidly by biting humans. This form of the disease is known as urban yellow fever or epidemic yellow fever.

Yellow fever epidemics also may occur after flooding caused by earthquakes and other natural disasters. They result from a combination of new habitats available for the vectors of the disease and changes in human behavior (spending more time outdoors and neglecting sanitation precautions).

Cases of yellow fever are uncommon in the United States and Canada as of 2010. The last reported case of a U.S. citizen dying of yellow fever concerned a man who contracted yellow fever after visiting Venezuela in 1999. The man had not been vaccinated against yellow fever. The last epidemic in the United States occurred in New Orleans in 1905.

Causes and symptoms

Once a mosquito has passed the yellow fever virus to a human, the chance of disease developing is about 5%–20%. Infection may be fought off by the host's immune system or may be so mild that it is never identified.

In human hosts who develop the disease yellow fever, there are five distinct stages through which the

WILBUR AUGUSTUS SAWYER (1879–1951)

Wilbur Augustus Sawyer was born in Appleton, Wisconsin, on August 7, 1879, to Minnie Edmea (Birge) and Wesley Caleb Sawyer. The Sawyers moved to Oshkosh, Wisconsin and finally to Stockton, California in 1888. Sawyer spent two years at the University of California and then entered Harvard College where he earned his A.B. degree in 1902. In 1906, Sawyer graduated from Harvard Medical School and began a private practice, which lasted until he started his internship at Massachusetts General Hospital. Sawyer returned to California in 1908 in order to obtain a position at the University of California as a medical examiner. He then worked with California State Board of Health from 1910 until 1918. In 1911, Sawyer married Margaret Henderson. The couple had three children.

Sawyer's first publication (1913) dealt with his research of poliomyelitis. His discovery, in 1915, that examination of the individual's stool could lead to detection of the disease was later regarded as very significant. In 1918 and 1919, Sawyer worked to control venereal disease while employed by the Army Medical Corps. In 1926 and 1927, while director of the West African Yellow Fever Commission, Sawyer succeeded in isolating the yellow fever virus. He would ultimately return to the United States, where he and Wray Lloyd would devise an immunization against yellow fever (1931).

In 1944, Sawyer became director of health for the United Nations Relief and Rehabilitation Administration, a position he held for three years. He retired to Berkeley, California, where he died on November 12, 1951. The company he built with his brother still thrives today.

infection evolves. These have been termed the periods of incubation, invasion, remission, intoxication, and convalescence.

Yellow fever's incubation period (the amount of time between the introduction of the virus into the host and the development of symptoms) is three to six days. During this time, there are generally no symptoms identifiable to the host.

The period of invasion lasts two to five days, and begins with an abrupt onset of symptoms, including fever and chills, intense **headache** and lower backache, muscle aches, **nausea**, and extreme exhaustion. The patient's tongue shows a characteristic white, furry coating in the center, surrounded by a swollen, reddened margin. While most other infections that cause a high fever also cause an increased heart rate, yellow fever results in an unusual finding, called Faget's sign. This is the simultaneous occurrence of a high fever with a slowed heart rate. Throughout the period of invasion, there are still live viruses circulating in the patient's bloodstream. Therefore, a mosquito can bite the ill patient, acquire the virus, and continue passing it on to others.

The next phase is the period of remission. The fever falls, and symptoms decrease in severity for several hours to several days. In some patients, this signals the end of the disease; in other patients, this proves only to be the calm before the storm.

The period of intoxication represents the most severe and potentially fatal phase of the illness. During this time, lasting three to nine days, a type of degeneration of the internal organs (specifically the kidneys, liver, and heart) occurs. This fatty degeneration results in what is considered the classic triad of yellow fever symptoms: **jaundice**, black vomit, and the dumping of protein into the urine. Jaundice causes the whites of the patient's eyes and the patient's skin to take on a distinctive yellow color. This is due to liver damage, and the accumulation of a substance called bilirubin, which is normally processed by a healthy liver. The liver damage also results in a tendency toward bleeding; the patient's vomit appears black due to the presence of blood. Protein, which is normally kept out of the urine by healthy, intact kidneys, appears in the urine due to disruption of the kidney's healthy functioning.

Patients who survive the period of intoxication enter into a relatively short period of convalescence. They recover with no long-term effects related to the yellow fever infection. Infection with the yellow fever virus results in lifelong immunity against repeated infection with the virus.

The course of yellow fever is complicated in some patients by secondary bacterial infections.

Diagnosis

Examination

A diagnosis of yellow fever may be suspected during a physical exam when the classic triad of symptoms are present. These include:

- a sudden onset of fever, chills, intense headaches and lower backaches, muscle aches, nausea, and exhaustion
- Faget's sign—simultaneous occurance of a high fever and increased heart rate
- a white furry coating in the center of the tongue surround by a swollen, red margin

KEY TERMS

Antibody—A protein normally produced by the immune system to fight infection or rid the body of foreign material. The material that stimulates the production of antibodies is called an antigen. Specific antibodies are produced in response to each different antigen and can only inactivate that particular antigen.

Antigen—Any foreign substance, usually a protein, that stimulates the body's immune system to produce antibodies.

Bilirubin—A reddish-yellow bile pigment made by the liver.

Dialysis—The cleansing of the blood through use of a special machine that filters the blood. Dialysis is done when the kidneys are unable to filter blood properly.

Epidemic—A situation in which a particular disease spreads rapidly through a population of people in a relatively short period of time.

Faget's sign—The simultaneous occurrence of a high fever with a slowed heart rate.

Flavivirus—The virus that causes yellow fever.

Hemorrhage—Abnormal and obsessive bleeding.

Host—The organism (such as a monkey or human) in which another organism (such as a virus or bacteria) is living.

Jaundice—The yellowing of the skin and whites of the eyes caused by an increased level of bilirubin in the blood.

Sylvatic—Pertaining to or living in the woods or forested areas. The form of yellow fever transmitted by mosquitoes to rainforest monkeys is called sylvatic yellow fever.

Vector—A carrier organism (such as a fly or mosquito) that serves to deliver a virus (or other agent of infection) to a host.

Tests

Diagnosis of yellow fever depends on the examination of blood by various techniques in order to demonstrate either yellow fever viral antigens (the part of the virus that stimulates the patient's immune system to respond) or specific antibodies (specific cells produced by the patient's immune system that are directed against the yellow fever virus). The most rapid method of diagnosis as of 2010 was capture enzyme immunoassay.

Procedures

Typically, the only procedure required for diagnosis is a blood draw so that the blood can be evaluated for signs of yellow fever.

Treatment

Traditional

As of 2010, the only treatments for yellow fever are given to relieve its symptoms. Fevers and **pain** should be relieved with **acetaminophen**, not **aspirin** or ibuprofen, both of which could increase the already-present risk of bleeding. **Dehydration** (due to fluid loss both from fever and bleeding) needs to be carefully avoided. This can be accomplished by increasing fluids. The risk of bleeding into the stomach can be decreased through the administration of **antacids** and other medications. Hemorrhage (heavy bleeding) may require blood transfusions. Kidney failure may require dialysis (a process that allows the work of the kidneys in clearing the blood of potentially toxic substances to be taken over by a machine, outside of the body).

Drugs

There are no antiviral treatments available as of 2010 to combat the yellow fever virus. Nonclinical research has led to limited results.

Researchers have found that ribavirin (Virazole, Rebetol), a drug that is given by mouth to treat **hepatitis C**, is successful in reducing mortality from yellow fever in hamsters, but only if given within 120 hours of infection. Another drug, Interferon-alpha has also been found to reduce mortality in monkeys with yellow fever but only when administered within 24 hours of infection.

Alternative

Prognosis

Five to ten percent of all diagnosed cases of yellow fever are fatal. Jaundice occurring during a yellow fever infection is an extremely grave predictor; 20-50% of these patients die of the infection. **Death** may occur due to massive bleeding (hemorrhage), often following a lapse into a comatose (unconscious) state.

Prevention

A very safe and very effective yellow fever vaccine exists. The Arilvax vaccine is made from a live attenuated (weakened) form of the yellow fever virus, strain 17D. In the United States, the vaccine is given only at Yellow Fever **Vaccination** Centers authorized by the United States Public Health Service. About 95% of vaccine recipients acquire long-term immunity to the yellow fever virus. Careful measures to decrease mosquito populations in both urban areas and jungle areas where humans are working, along with programs to vaccinate all people living in such areas, are necessary to avoid massive yellow fever outbreaks.

Individuals planning to travel to countries where yellow fever is endemic may obtain up-to-date information on yellow fever vaccination from the Centers for Disease Control and Prevention.

Yersinia enterocolitica infection *see* **Yersinosis**

Yersinia pestis see **Plague**

Yersinia pseudotuberculosis infection *see* **Yersinosis**

Yersinosis

Definition

Yersinosis refers to infection by a genus of bacteria known as *Yersinia*. The two sub-types that are responsible for yersinosis are *Yersinia enterocolitica* and *Yersinia pseudotuberculosis*. The diseases produced by these organisms are called "zoonoses," because the bacteria is passed to humans from animal sources.

The name *Yersinia* comes from Dr. Alexandre Yersin, who was the first person to grow a much more deadly type of *Yersinia* known as *Yersinia pestis*, the bacteria responsible for what is now known as bubonic **plague**. This article, however, will deal with the more common forms of *Yersinia*, namely *Y. enterocolitica* and *Y. pseudotuberculosis*.

Description

Yersinia are classified as gram-negative bacteria (bacteria that do not accept the color of a stain in a Gram stain test, which indicates the general chemical nature of the cell wall of the bacteria); they have a variety of appearances, and are therefore called pleomorphic. They belong to Enterobacteriacae, the large group of organisms that inhabit the intestinal tract. There are many different subtypes of *Yersinia*.

They are found worldwide and have been isolated from soil, fresh water, contaminated foods, and many wild and domestic animals. For reasons not entirely clear, disease caused by these organisms occurs more

frequently in areas of northern Europe, especially Scandinavia. Infection, particularly in children ages one through four years, is quite common, though often these infections produce few symptoms. Studies have shown that infection with these bacteria is almost as common as that with *Shigella* or *Campylobacter*.

Causes and symptoms

Animals are the most important sources of bacterial infection for humans. Whether from pets or undercooked meat (especially pork), these bacteria almost always enter the human body through the mouth (oral transmission). An incubation period of one to eleven days passes before signs of disease develop. Rare cases have been transmitted by way of contaminated blood transfusions.

Yersinia produces several different types of disease. The most common form is a short-lived inflammation of the intestine known as enterocolitis. Most often the very end of the small intestine is involved, an area known as the terminal ileum. The result is **gastroenteritis**, with cramping abdominal **pain**, **fever**, and **diarrhea**. Diarrhea generally continues for two weeks or so, but can go on for many months. Up to 40% of patients also experience **nausea and vomiting**, and in one-third, inflammation of the intestine leads to bleeding.

In other patients, the same area of the intestine is involved, but instead of causing diarrhea, a syndrome resembling **appendicitis** occurs. In this syndrome, the lymph nodes surrounding the intestine are especially involved; this has lead to the term mesenteric adenitis. Although this syndrome resolves without serious consequences, it is often difficult to differentiate from appendicitis, and leads to surgery in some instances. Ultrasound exam may be able to demonstrate a normal appendix and avoid surgery. Why some patients develop symptoms of gastroenteritis, and others only inflammation, pain, and fever, is unknown.

In some patients, *Yersinia* produces infection of areas other than the intestinal tract. These include:

- Inflammation of the throat (pharyngitis) and tonsillitis; this can be quite severe and even lead to death, particularly in adults.
- Septicemia, or infection of the blood stream, with spreading of infection to other organs such as bone, meninges, kidneys, and others. Individuals with decreased immunity due to liver disease, diabetes, cancer, and other diseases are at increased risk for this complication.

KEY TERMS

Mesenteric adenitis—Inflammation of the lymph nodes that serve the small intestine, with symptoms similar to appendicitis.

Septicemia—Systemic disease associated with the presence of microorganisms or their toxins in the blood; blood poisoning.

Different parts of the body may be affected (such as joints, eyes, and urinary system) by changes in the immune system caused by *Yersinia* infection. Arthritis, which is especially frequent in Scandinavia, occurs in up to 10% of *Yersinia* infections. About one week after typical intestinal symptoms, swelling and pain in multiple joints occurs. The knees and ankles are most often involved and become inflamed over a period of two weeks. In two-thirds of those affected, symptoms gradually resolve over one to three months without need for treatment. Rarely does chronic joint disease develop.

Inflammation of the heart muscle, called **myocarditis**, sometimes occurs together with the arthritis. In about 15%–20% of patients, the skin develops a red, raised area, usually located on the shins, called **erythema nodosum**. This appears within a few weeks of the intestinal symptoms and disappears over a month or so.

Diagnosis

Identifying *Yersinia* as the cause of all or any of these symptoms is not an easy task. It is possible to grow the organism from stool cultures, but this is difficult to do unless special methods are used.

A change in antibody levels can also be used to determine the presence of infection. To be accurate, levels must be initially examined early in the illness. Therefore, it is most important for the possible diagnosis and examination to be thought of early.

Treatment

Since most of the symptoms caused by *Yersinia* are self limiting, specific antibiotic treatment is generally not needed. Patients with **dehydration** from gastroenteritis are given supportive therapy, including treatment aimed at replacing fluids.

Antibiotics are indicated, however, for those patients who develop more severe infections, such as invasion of the bloodstream (septicemia), or who develop infections at specific sites, such as bone. A

variety of antibiotics have been used, but it is not clear which produces the best results.

No specific treatment is indicated for the joint, ocular, skin, or urinary symptoms that result from infection. As stated, these are not due to direct invasion by the bacteria, but are related to changes in immune reactions produced by the infection. However, treatment of those experiencing severe arthritic symptoms with NSAIDS (**nonsteroidal anti-inflammatory drugs**) or steroid injection at inflamed joints is used in selected cases.

Prognosis

As noted, most of the time, *Yersinia* infection has an excellent outlook. However, when these bacteria invade the bloodstream or produce disease beyond the gastrointestinal tract, the outlook is less positive. This may be because more severe infections occur in those with decreased immunity. The **death** rate from septicemia has been reported to be as high as 50%.

Prevention

Safe food handling procedures and food-preparation practices are by far the best means of avoiding infection. Undercooked food, especially pork or other animal products, should not be eaten.

Yoga positions

Name	Description
Boat	Sitting on floor with knees bent, extend legs out at a 45-degree angle to the floor so that body forms a "V" shape. Arms should be parallel to the ground.
Bridge	Lying on back with knees bent and feet flat on floor, raise pelvis off floor and arch back, keeping shoulders pressed to the ground.
Camel	While kneeling, arch back and bend head back toward feet. Hold heels with hands and exhale while in movement.
Cat-cow	On hands and knees, arch back and inhale, looking at ceiling. On exhale, round back and drop head down.
Child	Kneeling with arms to the side, roll torso to floor and rest forehead on the ground.
Cobra	Stretched out on floor with stomach down, align elbows beneath shoulders and raise torso up. Arms should straighten with hands flat on floor.
Corpse	Lie on back with feet and arms outstretched. Breathe deeply.
Downward Dog	From hands and knees, form an inverted "V" by straightening legs and pressing hands and heels to floor. Exhale while in movement.
Locust	Lying on stomach with hands at sides, squeeze buttocks and lift legs up off the ground. Simultaneously lift head, chest, and arms.
Mountain	Standing with feet together, inhale while raising arms straight above the head and clasp hands together. Exhale while lowering arms.
Spinal twist	Sitting with right foot crossed over left leg, grasp right leg with left arm and twist to the right. Repeat on other side.
Tree	While standing, place one foot on the inside of the opposite thigh. Place hands in prayer position in front of chest, and then extend toward ceiling.
Triangle	Standing with legs slightly wider than hip width, turn one foot out and reach for that foot, extending opposite arm toward ceiling.
Warrior I	Raise arms over head with palms together and lunge forward with one foot, keeping thigh parallel to the ground.
Warrior II	From Warrior I, rotate back foot so that it is perpendicular with front heel and extend arms straight out to sides. Look out over front hand.

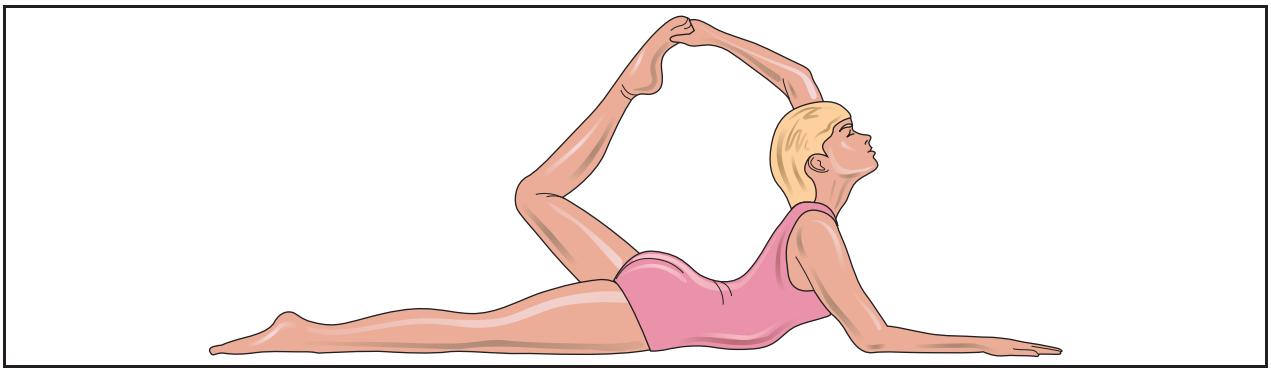
Yoga

Definition

The term *yoga* comes from a Sanskrit word which means yoke or union. Traditionally, yoga is a method joining the individual self with the Divine, Universal Spirit, or Cosmic Consciousness. Physical and mental exercises are designed to help achieve this goal, also called self-transcendence or enlightenment. On the physical level, yoga postures, called *asanas*, are designed to tone, strengthen, and align the body. These postures are performed to make the spine supple and healthy and to promote blood flow to all the organs, glands, and tissues, keeping all the bodily systems healthy. On the mental level, yoga uses breathing techniques (*pranayama*) and **meditation** (*dyana*) to quiet, clarify, and discipline the mind. However, experts are quick to point out that yoga is not a religion, but a way of living with health and peace of mind as its aims.

Purpose

Yoga has been used to alleviate problems associated with high blood pressure, high cholesterol,



Yoga is a system that benefits the body, mind, and spirit by teaching self-control through a series of postures and exercises as well as through breathing, relaxation, and meditation techniques. *(Illustration by Electronic Illustrators Group. Reproduced by permission of Gale, a part of Cengage Learning.)*

migraine headaches, **asthma**, shallow breathing, backaches, **constipation**, diabetes, **menopause**, **multiple sclerosis**, **varicose veins**, **carpal tunnel syndrome**, and many chronic illnesses. It also has been studied and approved for its ability to promote relaxation and reduce **stress**.

As of late 2002, yoga is increasingly recommended for **dysmenorrhea**, **premenstrual syndrome**, and other disorders in premenopausal women in Europe as well as in the United States.

Yoga can also provide the same benefits as any well-designed **exercise** program, increasing general health and stamina, reducing stress, and improving those conditions brought about by sedentary lifestyles. Yoga has the added advantage of being a low-impact activity that uses only gravity as resistance, which makes it an excellent **physical therapy** routine; certain yoga postures can be safely used to strengthen and balance all parts of the body. A study published in late 2002 summarized recent findings about the benefits of yoga for the cardiovascular and musculoskeletal systems. The review noted that yoga is still viewed as a "trendy" form of exercise rather than one with documented medical benefits.

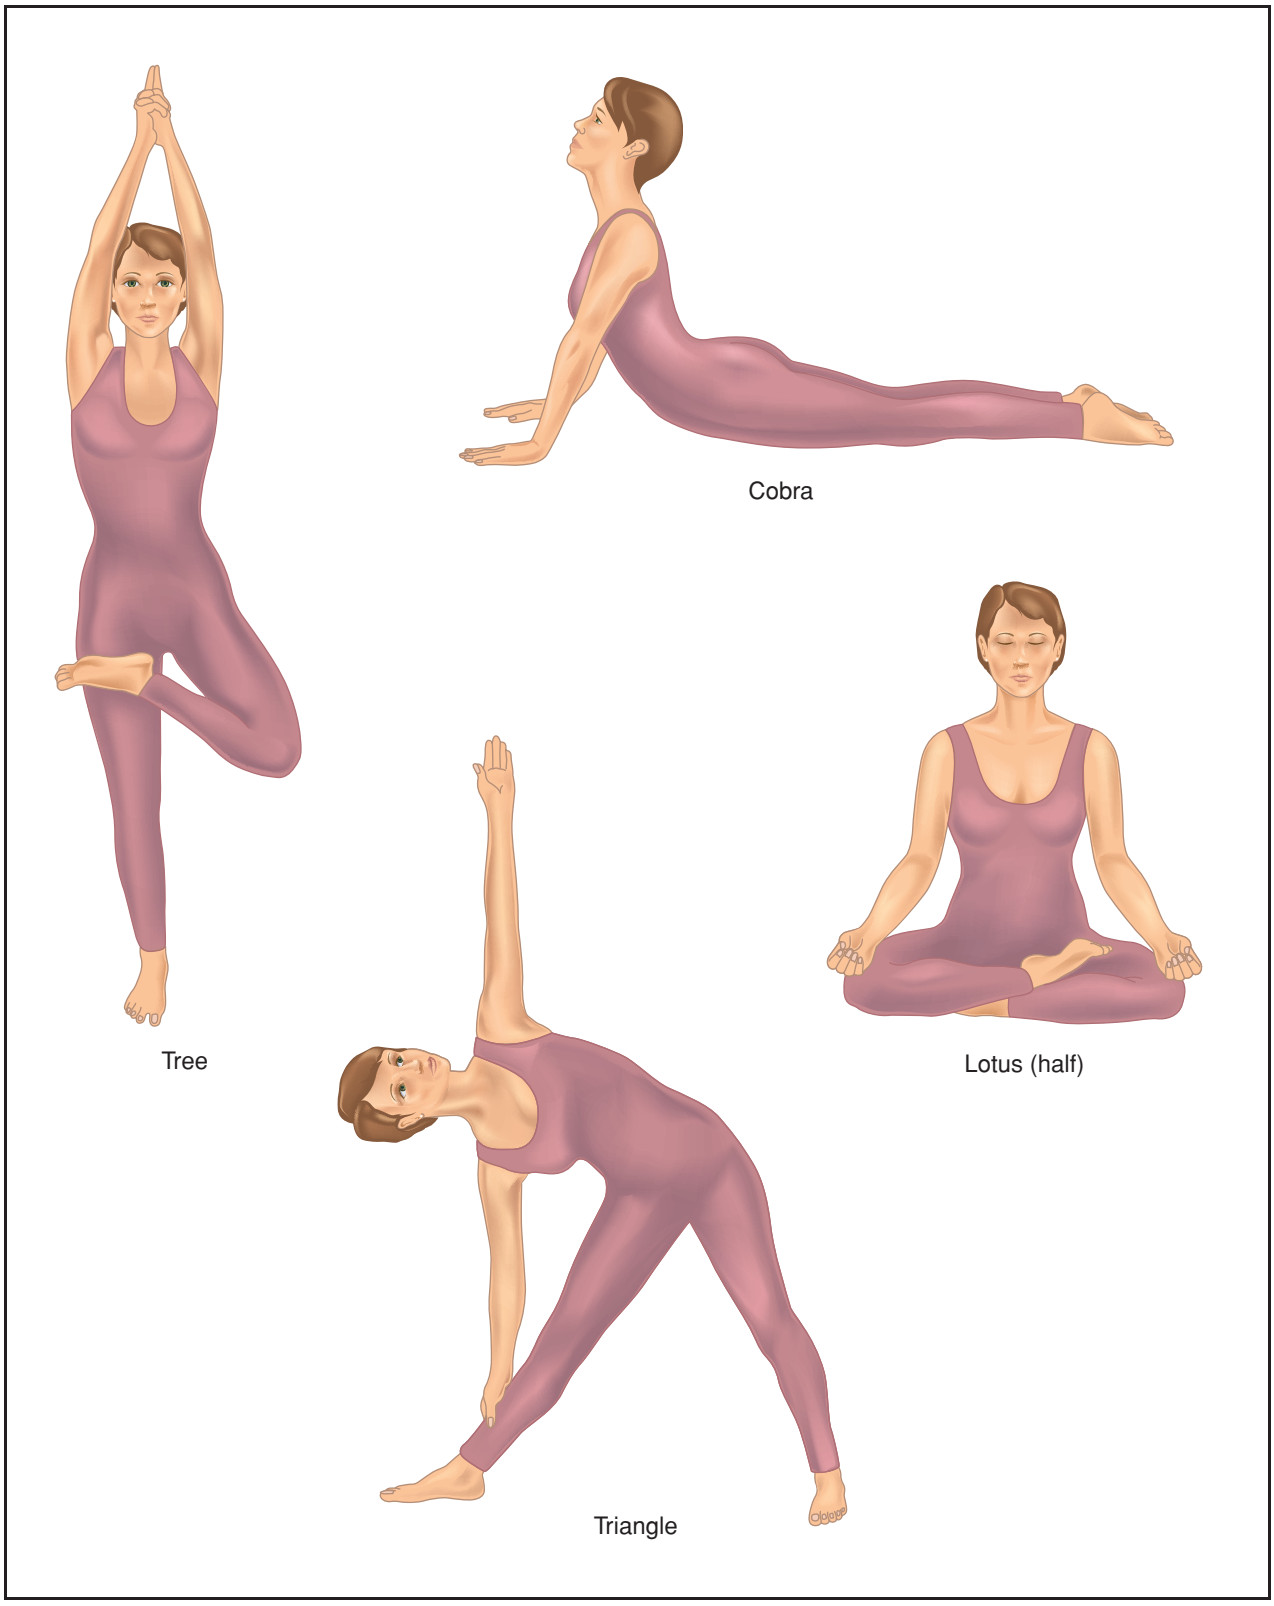
Meditation has been much studied and approved for its benefits in reducing stress-related conditions. The landmark book *The Relaxation Response*, by Harvard cardiologist Herbert Benson, showed that meditation and breathing techniques for relaxation could have the opposite effect of stress, reducing blood pressure and other indicators. Since then, much research has reiterated the benefits of meditation for **stress reduction** and general health. Currently, the American Medical Association recommends meditation techniques as a first step before medication for borderline **hypertension** cases. Some 2002 studies indicate that yogic meditation by itself is effective in lowering serum cholesterol as well as blood pressure.

Modern psychological studies have shown that even slight facial expressions can cause changes in the involuntary nervous system; yoga utilizes the mind/body connection. That is, yoga practice contains the central ideas that physical posture and alignment can influence a person's mood and self-esteem, and also that the mind can be used to shape and heal the body. Yoga practitioners claim that the strengthening of mind/body awareness can bring eventual improvements in all facets of a person's life.

Description

Origins

Yoga originated in ancient India and is one of the longest surviving philosophical systems in the world. Some scholars have estimated that yoga is as old as 5,000 years; artifacts detailing yoga postures have been found in India from over 3000 B.C. Yoga masters (*yogis*) claim that it is a highly developed science of healthy living that has been tested and perfected for all these years. Yoga was first brought to the United States in the late 1800s when Swami Vivekananda, an Indian teacher and yogi, presented a lecture on meditation in Chicago. Yoga slowly began gaining followers, and flourished during the 1960s when there was a surge of interest in Eastern philosophy. There has since been a vast exchange of yoga knowledge in the United States, with many students going to India to study and many Indian experts coming here to teach, resulting in the establishment of a wide variety schools. Today, yoga is thriving, and it has become easy to find teachers and practitioners throughout the United States. A recent Roper poll, commissioned



Demonstrations of the tree, triangle, cobra, and lotus poses. The tree and triangle are good for balance and coordination. Cobra stretches the pelvic and strengthens the back. Lotus is a meditative pose. *(Illustration by Electronic Illustrators Group. Reproduced by permission of Gale, a part of Cengage Learning.)*

PATANJALI (SECOND CENTURY B.C.)

There is little historical information available on Patanjali, who is credited with developing yoga, one of the six systems of Hindu philosophy. Several scholars suggest several persons may have developed yoga under the pseudonym of Patanjali. In any case, Patanjali existed around 150 B.C. in India. He developed yoga based on a loose set of doctrines and practices from the Upanishads, themselves a set of mystical writings. The Upanishads are part of the Aranyakas, philosophical concepts that are part of the Veda, the most ancient body of literature of Hinduism. Patanjali gave these combined philosophical and esoteric writings a common foundation in his *Yoga Sutra*, a set of 196 concise aphorisms (wise sayings) that form the principles of yoga. He also drew upon Samkhya, the oldest classic system of Hindu philosophy. Patanjali's yoga accepted Samkhya metaphysics and the concept of a supreme soul. He established an eight-stage discipline of self-control and meditation. The individual sutras (verses) lay out the entire tradition of meditation. They also describe the moral and physical disciplines needed for the soul to attain absolute freedom from the body and self.

by *Yoga Journal*, found that 11 million Americans do yoga at least occasionally and 6 million perform it regularly. Yoga stretches are used by physical therapists and professional sports teams, and the benefits of yoga are being touted by movie stars and *Fortune* 500 executives. Many prestigious schools of medicine have studied and introduced yoga techniques as proven therapies for illness and stress. Some medical schools, like UCLA, even offer yoga classes as part of their physician training program.

Classical yoga is separated into eight limbs, each a part of the complete system for mental, physical and spiritual well-being. Four of the limbs deal with mental and physical exercises designed to bring the mind in tune with the body. The other four deal with different stages of meditation. There are six major types of yoga, all with the same goals of health and harmony but with varying techniques: hatha, raja, karma, bhakti, jnana, and tantra yoga. **Hatha yoga** is the most commonly practiced branch of yoga in the United States, and it is a highly developed system of nearly 200 physical postures, movements and breathing techniques designed to tune the body to its optimal health. The yoga philosophy believes the breath to be the most important facet of health, as the breath is the largest source of *prana*, or life force, and hatha yoga utilizes *pranayama*, which literally means the science or control of breathing. Hatha yoga was originally developed as a system to make the body strong and healthy enough to enable mental awareness and spiritual enlightenment.

There are several different schools of hatha yoga in the United States; the two most prevalent ones are Iyengar and ashtanga yoga. Iyengar yoga was founded by B.K.S. Iyengar, who is widely considered as one of the great living innovators of yoga. Iyengar yoga puts strict emphasis on form and alignment, and uses traditional hatha yoga techniques in new manners and sequences. Iyengar yoga can be good for physical therapy because it allows the use of props like straps and blocks to make it easier for some people to get into the yoga postures. Ashtanga yoga can be a more vigorous routine, using a flowing and dance-like sequence of hatha postures to generate body heat, which purifies the body through sweating and deep breathing.

The other types of yoga show some of the remaining ideas which permeate yoga. Raja yoga strives to bring about mental clarity and discipline through meditation, simplicity, and non-attachment to worldly things and desires. Karma yoga emphasizes charity, service to others, non-aggression, and non-harming as means to awareness and peace. Bhakti yoga is the path of devotion and love of God, or Universal Spirit. Jnana yoga is the practice and development of knowledge and wisdom. Finally, tantra yoga is the path of self-awareness through religious rituals, including awareness of sexuality as sacred and vital.

A typical hatha yoga routine consists of a sequence of physical poses, or asanas, and the sequence is designed to work all parts of the body, with particular emphasis on making the spine supple and healthy and increasing circulation. Hatha yoga asanas utilize three basic movements: forward bends, backward bends, and twisting motions. Each asana is named for a common thing it resembles, like the sun salutation, cobra, locust, plough, bow, eagle, tree, and the head to knee pose, to name a few. Each pose has steps for entering and exiting it, and each posture requires proper form and alignment. A pose is held for some time, depending on its level of difficulty and one's strength and stamina, and the practitioner is also usually aware of when to inhale and exhale at certain points in each posture, as breathing properly is another fundamental aspect of yoga. Breathing should be deep and through the nose. Mental concentration in each position is also very important, which improves awareness, poise and posture. During a yoga routine there is often a position in which to perform meditation, if deep relaxation is one of the goals of the sequence.

Yoga routines can take anywhere from 20 minutes to two or more hours, with one hour being a good time

investment to perform a sequence of postures and a meditation. Some yoga routines, depending on the teacher and school, can be as strenuous as the most difficult workout, and some routines merely stretch and align the body while the breath and heart rate are kept slow and steady. Yoga achieves its best results when it is practiced as a daily discipline, and yoga can be a life-long exercise routine, offering deeper and more challenging positions as a practitioner becomes more adept. The basic positions can increase a person's strength, flexibility, and sense of well-being almost immediately, but it can take years to perfect and deepen them, which is an appealing and stimulating aspect of yoga for many.

Yoga is usually best learned from a yoga teacher or physical therapist, but yoga is simple enough that one can learn the basics from good books on the subject, which are plentiful. Yoga classes are generally inexpensive, averaging around 10 dollars per class, and students can learn basic postures in just a few classes. Many YMCAs, colleges, and community health organizations offer beginning yoga classes as well, often for nominal fees. If yoga is part of a physical therapy program, its cost can be reimbursed by insurance.

Preparations

Yoga can be performed by those of any age and condition, although not all poses should be attempted by everyone. Yoga is also a very accessible form of exercise; all that is needed is a flat floor surface large enough to stretch out on, a mat or towel, and enough overhead space to fully raise the arms. It is a good activity for those who can't go to gyms, who don't like other forms of exercise, or have very busy schedules. Yoga should be done on an empty stomach, and teachers recommend waiting three or more hours after meals. Loose and comfortable clothing should be worn.

Precautions

People with injuries, medical conditions, or spinal problems should consult a doctor before beginning yoga. Those with medical conditions should find a yoga teacher who is familiar with their type of problem and who is willing to give them individual attention. Pregnant women can benefit from yoga, but should always be guided by an experienced teacher. Certain yoga positions should not be performed with a **fever** or during menstruation.

Beginners should exercise care and concentration when performing yoga postures and not try to stretch too much too quickly as injury could result. Some advanced yoga postures, like the headstand and full lotus position, can be difficult and require strength, flexibility, and gradual preparation, so beginners should get the help of a teacher before attempting them.

Yoga is not a competive sport; it does not matter how a person does in comparison with others, but how aware and disciplined one becomes with one's own body and limitations. Proper form and alignment should always be maintained during a stretch or posture, and the stretch or posture should be stopped when there is **pain**, **dizziness**, or **fatigue**. The mental component of yoga is just as important as the physical postures. Concentration and awareness of breath should not be neglected. Yoga should be done with an open, gentle, and non-critical mind; when one stretches into a yoga position, it can be thought of accepting and working on one's limits. Impatience, self-criticism, and comparing oneself to others will not help in this process of self-knowledge. While performing the yoga of breathing (pranayama) and meditation (dyana), it is best to have an experienced teacher, as these powerful techniques can cause dizziness and discomfort when done improperly.

Side effects

Some people have reported injuries by performing yoga postures without proper form or concentration, or by attempting difficult positions without working up to them gradually or having appropriate supervision. Beginners sometimes report muscle soreness and fatigue after performing yoga, but these side effects diminish with practice.

Research and general acceptance

Although yoga originated in a culture very different from that of the modern United States, it has been

KEY TERMS

Asana—A position or stance in yoga.

Dyana—The yoga term for meditation.

Hatha yoga—Form of yoga using postures, breathing methods and meditation.

Meditation—Technique of concentration for relaxing the mind and body.

Pranayama—Yoga breathing techniques.

Yogi (female, yogini)—A trained practitioner of yoga.

accepted and its practice has spread relatively quickly. Many yogis are amazed at how rapidly yoga's popularity has spread in the United States and Canada, considering the legend that it was passed down secretly by handfuls of adherents for many centuries.

There can still be found some resistance to yoga, for active and busy Americans sometimes find it hard to believe that an exercise program that requires them to slow down, concentrate, and breathe deeply can be more effective than lifting weights or running. However, ongoing research in top medical schools is showing yoga's effectiveness for overall health and for specific problems, making it an increasingly acceptable health practice.

The growing acceptability of yoga as an alternative therapy for certain disorders or conditions is reflected in the fact that the National Center for Complementary and Alternative Medicine (NCCAM) is conducting a series of clinical trials of yoga. As of December 2010, NCCAM has four clinical trials in progress, evaluating yoga as a treatment for **menopause**, **post-traumatic stress disorder**, and arthritis.

Zellweger syndrome

Definition

Zellweger syndrome (ZS) is the most severe of three very rare, inherited, related metabolic disorders known collectively as the Zellweger spectrum. ZS affects all of the major organs of the body, especially the brain, liver, and kidneys. It is almost always fatal within the first year of life.

Demographics

The worldwide incidence of Zellweger syndrome is estimated to be about one in 100,000 births. The incidence of Zellweger spectrum is estimated at about one in 50,000.

Description

Zellweger syndrome and the other two disorders that constitute Zellweger spectrum—neonatal **adrenoleukodystrophy** (NALD) and infantile Refsum disease (IRD)—are peroxisome biogenesis disorders (PBDs). PBDs are inherited defects or mutations in genes that are involved in the formation of peroxisomes. Peroxisomes are small sac–like compartments or organelles in all human cells. Peroxisomes are surrounded by a membrane and contain enzymes that break down or oxidize many different substances, especially fatty acids and certain toxins. For example, when large amounts of alcohol are consumed, 5 to 25 percent of the ethanol is oxidized and detoxified in peroxisomes. Peroxisomes also are important for the synthesis of some key compounds in the body, including hormones and fats (lipids) that are required by the nervous system and for digestion. Peroxisomes are especially important in the brain, liver, and kidneys. In peroxisome biogenesis disorders, defective genes prevent peroxisomes from forming correctly, resulting in an absence of peroxisomes or malformed peroxisomes that cannot perform their functions adequately.

Peroxisomes are essential for the formation and maintenance of myelin. Myelin is the substance that covers and protects nerves and promotes the efficient transmission of nerve impulses. The parts of the brain and spinal cord that contain myelin are called the white matter and include the cerebral cortex of the brain. Therefore peroxisome biogenesis disorders interfere with brain development. The destruction of the myelin (demyelination) causes the loss of white matter or leukodystrophy. Therefore, PBDs are members of a larger group of inherited disorders known as leukodystrophies. Leukodystrophies also affect the metabolism of some substances.

The brain abnormalities of Zellweger syndrome are caused by disruption of neuroblast migration in the fetus during about the third month of gestation. Neuroblasts are cells that develop into nerve cells, called neurons. This defect leads to small thick convolutions in the cerebral tissue of the brain and distinguishes Zellweger syndrome from other brain abnormalities.

After birth, defects in these same genes that cause the brain abnormalities of Zellweger syndrome also cause the reduction in or elimination of peroxisomes. The absence of peroxisomes in the liver and kidney cells of babies with Zellweger syndrome was first demonstrated in 1985 by the American pathologist S. L. Goldfischer. This absence of peroxisomes is now considered to be the hallmark of Zellweger syndrome. Babies with Zellweger syndrome also have far fewer peroxisomes in their brain cells. The fibroblasts of the skin appear to have ghost–like peroxisomes because the organelles lack certain proteins. Development of the heart, cartilage, and muscle also are affected in Zellwinger syndrome.

Risk factors

Newborns are at risk for Zellweger syndrome if each parent carries an abnormal copy of a gene responsible for the disorder. Zellweger syndrome is inherited as an autosomal recessive trait. “Autosomal” means that the genes that are responsible for ZS are not located on the X or Y sex chromosomes and therefore affect males and

KEY TERMS

Amniocentesis—The insertion of a needle through the mother's abdomen into the uterus at 16–18 weeks of gestation to withdraw a small sample of the amniotic fluid surrounding the fetus to test for genetic disorders and other medical conditions.

Autosomal—Located on a chromosome other than the X or Y sex chromosomes.

Fibroblast—A connective–tissue cell.

Leukodystrophy—Any of several inherited diseases characterized by the degeneration of myelin in the brain, spinal cord, and peripheral nerves.

Myelin—Soft white material composed of lipids (fats) and protein that forms a thick sheath around nerve cells.

Neuroblast—An embryonic nerve cell that differentiates into a neuron.

Peroxins—Proteins that are responsible for forming the peroxisomal membrane and transporting other proteins into the peroxisome; these proteins are encoded by various PEX genes.

Peroxisome—A cellular organelle or microbody that contains various enzymes that are responsible for the production of cellular components and the breakdown of toxic waste products.

Peroxisome biogenesis disorder; PBD—An inherited disorder, such as Zellweger syndrome and other Zellweger spectrum disorders, that disrupt the formation and functioning of peroxisomes.

Plasmalogen—Any of a group of phospholipids; plasmalogen synthesis is disrupted in ZS.

Recessive—A gene or trait whose effects are apparent only in the absence of a corresponding dominant gene or trait.

Zellweger spectrum—Three peroxisome biogenesis disorders—Zellwinger syndrome, neonatal adrenoleukodystrophy, and infantile Refsum disease—which can be caused by different mutations in the same genes and which differ only in the severity of the resulting condition.

females with equal frequency. "Recessive" means that Zellweger syndrome only occurs in individuals with two defective gene copies, one inherited from each parent. Although the parents each carry one copy of the mutated gene, they typically have no signs and symptoms of the condition. However each of their offspring has a 25% chance of having Zellwinger syndrome and a 50% chance of inheriting one abnormal gene, thereby becoming a ZS "carrier."

Causes and symptoms

Zellweger syndrome is caused by mutations or defects in any one of several genes that encode proteins called peroxins that are essential for the formation (biogenesis) and normal functioning of peroxisomes. Peroxins produce the peroxisome membrane and import enzymes into the organelle. Mutations in at least 12 different genes can result in Zellweger spectrum. These genes are located on different chromosomes and encode distinct peroxin proteins. Defects in the peroxin–1 protein encoded by the PEX1 gene account for about 70% of Zellweger spectrum disorders. Zellweger syndrome is caused by severe defects in PEX1 or other PEX genes that result in peroxisomes that are essentially nonfunctional.

The symptoms of Zellweger syndrome are apparent at birth. They include distinct facial, developmental, and ocular (eye) features, some of which are due to high levels of iron and copper in the blood and tissues. These signs and symptoms include:

- a flattened face
- high forehead
- broad nasal bridge
- up–slanted eyes
- skin folds—called epicanthal folds—between the upper and lower eyelids along the nasal border
- underdeveloped eyebrow ridges
- deformed ear lobes
- neurological abnormalities, such as mental retardation and seizures
- an enlarged liver
- severe weakness and lack of muscle tone—sometimes to the degree that the infant is unable to move, suck, or swallow
- ocular abnormalities that can affect vision, including glaucoma and retinal degeneration
- hearing impairment
- cysts on the kidneys
- sometimes jaundice or gastrointestinal bleeding

Diagnosis

Examination

Although the distinctive shape of the head and facial features are diagnostic for Zellweger spectrum, in some cases it can be difficult to distinguish between Zellweger syndrome and the other related conditions of the spectrum.

Tests

Zellweger syndrome is usually diagnosed through biochemical tests of the blood, urine, and fibroblasts. The most commonly used test is a measurement of very–long–chain fatty acids (VLCFA), which accumulate to high levels in the blood plasma with ZS. Blood levels of other fatty acids, pipecolic acid, and bile acid intermediates are also typically elevated. Plasmalogen levels are diminished.

A medical geneticist may confirm the diagnosis through detection of DNA mutations in one of the 12 different PEX genes located on chromosomes 1, 2, 6, 7, 8, 11, 12, 17, and 22. A PEX1 gene mutation is the most common cause of Zellweger syndrome. Genetic studies are accomplished with a small blood sample.

Procedures

Fatty acid levels and plasmalogen synthesis can be detected before birth using amniocentesis—the withdrawal through the mother's abdomen of fetal cells in the amniotic fluid.

Various procedures may be used to detect life–threatening problems in other organs and tissues, including the liver, heart, and kidneys. X rays can detect skeletal abnormalities, including a large space between the bones of the skull and characteristic bone spots called chondrodysplasia punctata.

Treatment

Traditional

There is neither a cure for Zellweger syndrome nor a standard course of treatment. Since most of the neurological and metabolic abnormalities are caused during fetal development, treatments after birth are severely limited. The goal is to lessen symptoms and support the involved organs. In addition to physicians and nurses, physical, occupational, respiratory, and speech therapists provide supportive strategies and devices to maintain posture, independent breathing, eating, speech, and other developmentally appropriate activities for as long as is practical. It is important to protect against infection in order to delay the development of complications. Support services are available for family members.

Drugs

Infants may be treated with vitamin K to prevent abnormal bleeding. Some patients have improved with experimental therapies using docosahexaenoic acid (DHA), an omega–3 essential fatty acid that is deficient with Zellweger syndrome. The administration of bile acids, such as cholic acid or chenodeoxycholic acid, is being tested for improvement of liver function.

Prognosis

Most infants with Zellweger syndrome do not survive past their first six months and rarely live more than one year after diagnosis. **Death** is usually due to respiratory distress, liver failure, severe feeding difficulties, heart defects, and/or gastrointestinal bleeding.

Prevention

Because Zellweger syndrome is usually fatal within the first year of life, **genetic counseling** and prenatal diagnosis are usually a high priority for parents who are at risk of conceiving an afflicted child, particularly couples who have had a previous child with Zellweger syndrome. Prospective parents with family histories of Zellweger syndrome or spectrum may be able to undergo genetic screening to determine the likelihood of their conceiving an afflicted child.

Zoonosis

Definition

Zoonosis, also called *zoonotic disease*, refers to diseases that can be passed from animals, whether wild or domesticated, to humans.

Description

Although many diseases are species specific, meaning that they can only occur in one animal species, many other diseases can be spread between different animal species. These are infectious diseases, caused by bacteria, viruses, or other disease causing organisms that can live as well in humans as in other animals.

There are different methods of transmission for different diseases. In some cases, zoonotic diseases are transferred by direct contact with infected animals, much as being near an infected human can cause the spread of an **infectious disease**. Other diseases are spread by drinking water that contains the eggs of parasites. The eggs enter the water supply from the feces of infected animals. Still others are spread by eating the flesh of infected animals. Tapeworms are spread this way. Other diseases are spread by insect vectors. An insect, such as a flea or tick, feeds on an infected animal, then feeds on a human. In the process, the insect transfers the infecting organism.

The Centers for Disease Control (CDC) in Atlanta have said that most emerging diseases around the world are zoonotic. The director of the CDC has said that 11 of the last 12 emerging infections in the world with serious health consequences has probably arisen from animal sources. Wild animal trade occurs across countries and many people take in wild animals as domestic pets. However, pet shops and food markets are not properly testing for diseases and parasites that can cause harm to humans and other animals.

Some zoonotic diseases are well known, such as rats (**plague**) and deer ticks (**Lyme disease**). Others are not as well known. For example, elephants may develop **tuberculosis** and spread it to humans.

Causes and symptoms

The following is a partial list of animals and the diseases that they may carry. Not all animal carriers are listed, nor are all the diseases that the various species may carry.

- Bats are important rabies carriers and also carry several other viral diseases that can affect humans.
- Cats may carry the causative organisms for plague, anthrax, cowpox, tapeworm, and many bacterial infections.
- Dogs may carry plague, tapeworm, rabies, Rocky Mountain Spotted Fever, and Lyme disease.
- Horses may carry anthrax, rabies, and *Salmonella* infections.
- Cattle may carry the organisms that cause anthrax, European tick-borne encephalitis, rabies, tapeworm, *Salmonella* infections, and many bacterial and viral diseases.
- Pigs are best known for carrying tapeworm, but may also carry a large number of other infections including anthrax, influenza, and rabies.
- Sheep and goats may carry rabies, European tick-borne encephalitis, *Salmonella* infections, and many bacterial and viral diseases.
- Rabbits may carry plague and Q-Fever.
- Birds may carry *Campylobacteriosis*, *Chlamydia psittaci*, *Pasteurella multocida*, *Histoplasma capsulatum*, *Salmonellosis*, and others.

Zoonotic diseases may be spread in different ways. Tapeworms can often spread to humans when people eat the infected meat of cattle and swine. Other diseases are transferred by insect vectors, often blood-feeding insects that carry the cause of the disease from one animal to another.

Diagnosis

Diagnosis of the disease is made in the usual manner, by identifying the infecting organism. Each disease has established symptoms and tests. Identifying the carrier may be easy or may be more difficult when the cause is a fairly common infection. For example, tapeworms are usually species specific. Cattle, pigs, and fish all carry

KEY TERMS

Anthrax—A disease of warm blooded animals, particularly cattle and sheep, transmissible to humans. The disease causes severe skin and lung damage.

Bovine spongiform encephalopathy—Also known as Mad Cow disease, a progressive, fatal disease of the nervous system of domestic animals that is transmitted by eating infected food.

Lyme disease—An acute disease which is usually marked by skin rash, fever, fatigue, and chills. Left untreated, it may cause heart and nervous system damage.

Q-Fever—A disease that is marked by high fever, chills, and muscle pain. It is seen in North America, Europe, and parts of Africa. It may be spread by drinking raw milk or by tick bites.

Zoonotic—A disease which can be spread from animals to humans.

different species of tapeworms, although all can be transmitted to humans who eat undercooked meat containing live tapeworm eggs. Once the tapeworm has been identified, it is easy to tell which species the tapeworm came from.

Other zoonotic infections may be harder to identify. Sometimes the infection is fairly common among both humans and animals, and it is impossible to tell. Snakes may carry the bacteria ***Escherichia coli*** and *Proteus vulgaris*, but since these bacteria are already common among humans, it would be difficult to trace infections back to snakes.

Because of increased trade between nations and changes in animal habitats, there are often new zoonotic diseases. These may be found in animals transported from one nation to another, bringing with them new diseases. In some cases, changes in the environment lead to changes in the migratory habits of animal species, bringing new infections.

Treatment

Treatment is the established treatment for the specific infection.

Prevention

Prevention of zoonotic infections may take different forms, depending on the nature of the carrier and the infection.

Some zoonotic infections can be avoided by immunizing the animals that carry the disease. Pets and other domestic animals should have **rabies** vaccinations, and wild animals are immunized with an oral vaccine that is encased in a suitable bait. In some places, the bait is dropped by airplane over the range of the potential rabies carrier. When the animals eat the bait, they also ingest the oral vaccine, thereby protecting them from rabies and reducing the risk of spread of the disease. This method has been used to protect foxes, coyotes, and other wild animals.

Many zoonotic diseases that are passed by eating the meat of infected animals can be prevented by proper cooking of the infected meat. Tapeworm infestations can be prevented by cooking, and *Salmonella* infections from chickens and eggs can be prevented by being sure that both the meat and the eggs are fully cooked.

For other zoonotic diseases, programs are in place to eliminate the host, or the vector, that spreads the disease. Plague is prevented by elimination of the rats—a common source of the infection—and of fleas that carry the disease from rats to humans. Efforts around the world to control bovine spongiform **encephalitis**, better known as Mad Cow disease, have focused on the destruction of infected cattle to prevent spread of the disease. Regulations on the makeup of the cattle feed to ensure safety and prevent the disease have helped curb its spread.

Other means of prevention simply rely on care. People living in areas where Lyme disease is common are warned to take precautions against the bite of the deer tick, which transfers the disease. These precautions include not walking in tall grass, not walking bare legged, and wearing light-colored clothing so that the presence of the dark ticks can be readily seen.

GLOSSARY

The following is an alphabetical compilation of terms and definitions listed in the *Key Terms* section of the main body entries. Although the list is comprehensive, it is by no means exhaustive.

25–HYDROXY–VITAMIN D. The form of vitamin D that is measured in order to assess vitamin D deficiency.

A

AADC INHIBITORS. Drugs that block the amino acid decarboxylase; one type of enzyme that breaks down dopamine. Also called DC inhibitors, they include carbidopa and benserazide.

ABDOMINAL AORTIC ANEURYSM. Occurs when an area in the aorta (the main artery of the heart) is weakened and bulges like a balloon. The abdominal section of the aorta supplies blood to the lower body.

ABDOMINAL DISTENSION. Swelling of the abdominal cavity, which creates painful pressure on the internal organs.

ABDOMINAL MIGRAINE. A variant form of a migraine headache; moderate to severe midline abdominal pain, usually occurring in children with a family history of migraine.

ABLATION. The removal of abnormal tissue growths by surgery.

ABLATIVE. Used to describe a procedure involving removal of a tissue or body part, or destruction of its funtion.

ABO ANTIGEN. Protein molecules located on the surfaces of red blood cells that determine a person's blood type: A, B, or O.

ABO BLOOD GROUPS. A system in which human blood is classified according to the A and B antigens found in red blood cells. Type A blood has the A antigen, type B has the B antigen, AB has both, and O has neither.

ABO BLOOD TYPE. Blood type based on the presence or absence of the A and B antigens on the red blood cells.

ABORTIVE. Referring to treatment that relieves symptoms of a disorder.

ABRASION. An area of the body whose surface has been worn away by some abnormal process.

ABROVIRUS VIRUSES. Also known as arthropod-borne viruses, these viruses are maintained in nature through biological transmission between vertebrate hosts and blood-feeding arthropods. Infection occurs when an infected arthropod, such as a mosquito, feeds off a vertebrate, such as a human.

ABSCESS. A collection of pus buried deep in the tissues or in a body cavity.

ABSORPTION. The transfer of a vitamin from the digestive tract to the bloodstream.

ABSORPTION SPECTROMETRY. A scientific procedure to determine chemical makeup of samples.

ABSTINENCE. Refraining from the use of alcoholic beverages.

ABUTMENT TOOTH. A crowned tooth that stabilizes a bridge or partial denture.

ACALCULOUS CHOLECYSTITIS. Inflammation of the gallbladder that occurs without the presence of gallstones.

ACAMPROSATE. An anti–craving medication used in Europe to reduce the craving for alcohol. It is presently undergoing tests for approval in the United States.

ACANTHOSIS NIGRICANS. A dark brownish or blackish discoloration of the skin related to overweight and high levels of insulin in the blood. Acanthosis nigricans is most likely to develop in the groin or armpits, or around the back of the neck.

ACCESS. The point where a needle or catheter is inserted for dialysis.

ACCESS SITE. The vein tapped for vascular access in hemodialysis treatments. For patients with temporary

treatment needs, access to the bloodstream is gained by inserting a catheter into the subclavian vein near the patient's collarbone. Patients in long-term dialysis require stronger, more durable access sites, called fistulas or grafts, that are surgically created.

ACCESSORY ORGAN. A lump of tissue adjacent to an organ that is similar to it, but which serves no important purpose, if functional at all. While not necessarily harmful, such organs can cause problems if they grow too large or become cancerous. In any case, their presence points to an underlying abnormality in the parent organ.

ACCOMMODATION. The ability of the eye to change its focus from near to distant objects.

ACETABULUM. The large cup-shaped cavity at the junction of pelvis and femur or thigh bone.

ACETAMINOPHEN. A drug for relieving pain and fever. Tylenol is the most common example.

ACETYLCHOLINE. A neurotransmitter with effects that are generally opposite those of dopamine and norepinephrine. Acetylcholine dilates blood vessels, lowers blood pressure, and slows heartbeat.

ACETYLCHOLINESTERASE. An enzyme that breaks down acetylcholine.

ACHALASIA. Failure of the lower end of the esophagus (or another tubular valve) to open, resulting in obstruction, either partial or complete.

ACHLORHYDRIA. An abnormal condition in which hydrochloric acid is absent from the secretions of the gastric glands in the stomach.

ACHROMATOPSIA. The inability to distinguish any colors.

ACID. Common street name for LSD.

ACID INDIGESTION. Stomach discomfort that results from too much acid in the stomach.

ACID-BASE BALANCE. A balance of acidity and alkalinity of fluids in the body that keeps the pH level of blood around 7.35–7.45.

ACID-FAST STAIN. A special stain done to microscopically identify the bacteria that cause tuberculosis.

ACIDOPHILUS. The bacteria *Lactobacillus acidophilus* usually found in yogurt.

ACIDOSIS. A disturbance of the balance of acid to base in the body causing an accumulation of acid or loss of alkali (base). There are two types of acidosis: metabolic and respiratory. One of the most common causes of metabolic acidosis is an overdose of aspirin. Respiratory acidosis is caused by impaired breathing caused by conditions such as severe chronic bronchitis, bronchial asthma, or airway obstruction.

ACINAR CELL CARCINOMA. A malignant tumor arising from the acinar cells of the pancreas.

ACNE. A chronic inflammation of the sebaceous glands that manifests as blackheads, whiteheads, and/or pustules on the face or trunk.

ACOUSTIC NEUROMA. A benign tumor that grows on the nerve leading from the inner ear to the brain. As the tumor grows, it exerts pressure on the inner ear and causes severe vertigo.

ACQUIRED IMMUNE DEFICIENCY SYNDROME (AIDS). HIV infection that has led to certain opportunistic infections, cancers, or a CD4+ T-lymphocyte (helper cell) blood cell count lower than 200/mL.

ACROCYANOSIS. A slight cyanosis, or blueness of the hands and feet of the neonate is considered normal. This impaired ability to fully oxygenate the extremities is due to an immature circulatory system which is still in flux.

ACROMEGALY. A rare disease resulting from excessive growth hormone caused by a benign tumor. If such a tumor develops within the first 10 years of life, the result is gigantism (in which growth is accelerated) and not acromegaly. Symptoms include coarsening of the facial features, enlargement of the hands, feet, ears, and nose, jutting of the jaw, and a long face.

ACTH. Adrenocorticotropic hormone, a hormone normally produced by the pituitary gland, sometimes taken as a treatment for arthritis and other disorders.

ACTINIC KERATOSIS (PLURAL, KERATOSES). A type of precancerous skin growth with a scaly or bumpy surface caused by overexposure to the sun.

ACTIVATED PARTIAL THROMBOPLASTIN TIME. Partial thromboplastin time test that uses activators to shorten the clotting time, making it more useful for heparin monitoring.

ACTIVE IMMUNIZATION. Treatment that provides immunity by challenging an individual's own immune system to produce antibody against a particular organism, in this case the rabies virus.

ACTIVE TREATMENT STAGE. The period during which orthodontic appliances or braces are used.

ACTIVITIES OF DAILY LIVING (ADL). The skills and practices that determine how well individuals function

in their daily lives and relate to and participate in their environment.

ACUPOINT. A pressure point stimulated in acupressure.

ACUPRESSURE. A form of acupuncture in which certain points of the body are pressed with the fingers and hands to release energy blocks.

ACUPUNCTURE. A treatment technique associated with traditional Chinese medicine, in which thin needles are inserted into specific points located along energy channels in the human body known as meridians.

ACUTE. Having a sudden onset and lasting a short time.

ACUTE INTERMITTENT PORPHYRIA. An inherited disease affecting the liver and bone marrow. The liver overproduces a specific acid and the disease is characterized by attacks of high blood pressure, abdominal colic, psychosis, and nervous system disorders.

ACUTE LYMPHOBLASTIC LEUKEMIA (ALL). A type of leukemia, also called acute lymphocytic leukemia, primarily in children, affecting lymphocytes.

ACUTE OTITIS MEDIA. Inflammation of the middle ear with signs of infection lasting less than three months.

ACUTE PAIN. Pain in response to injury or another stimulus that resolves when the injury heals or the stimulus is removed.

ACUTE PHASE REACTANT. A substance in the blood that increases as a response to an acute condition such as infection, injury, tissue destruction, some cancers, burns, surgery, or trauma.

ACUTE PRESCRIBING. Homeopathic treatment for self-limiting illnesses with abrupt onset.

ACUTE RENAL (KIDNEY) FAILURE. Abrupt loss of kidney function.

ACUTE RESPIRATORY DISTRESS SYNDROME. A serious reaction to various forms of injuries to the lung, which is characterized by inflammation of the lung, leading to impaired gas exchange and release of inflammatory mediators causing inflammation and low blood oxygen and frequently resulting in multiple organ failure. This condition is life threatening and often lethal, usually requiring mechanical ventilation and admission to an intensive care unit.

ACUTE RETROVIRAL SYNDROME (ARS). A syndrome that develops in about 30% of HIV patients within a few weeks of infection. ARS is characterized by nausea, vomiting, fever, headache, general tiredness, and muscle cramps.

ACYCLOVIR. An antiviral drug used for combating chickenpox and other herpes viruses.

ADDICTION. The state of being both physically and psychologically dependent on a substance or activity.

ADDICTIVE PERSONALITY. The concept that addiction is the result of pre-existing character defects.

ADDISON'S DISEASE. A disease characterized by a deficiency in adrenocortical hormones due to destruction of the adrenal gland.

ADENOCARCINOMA. Malignant cancers that originate in the tissues of glands or that form glandular structures.

ADENOCARCINOMA. Type of cancer beginning in glandular epithelium.

ADENOIDS. Common name for the pharyngeal tonsils, which are lymph masses in the wall of the air passageway (pharynx) just behind the nose.

ADENOMA. A type of noncancerous (benign) tumor that often involves the overgrowth of certain cells of the type normally found within glands.

ADENOMYOSIS. Uterine thickening caused when endometrial tissue, which normally lines the uterus, extends outward into the fibrous and muscular tissue of the uterus.

ADENOSINE. A nucleoside that plays multiple physiological roles in energy transfer and molecular signaling, as a component of RNA, and as an inhibitory neurotransmitter that promotes sleep.

ADENOSINE DEAMINASE (ADA). An enzyme that is lacking in a specific type of SCID. Children with an ADA deficiency have low levels of both B and T cells.

ADENOVIRUS. A virus that affects the upper respiratory tract.

ADHD. Attention deficit hyperactivity disorder; a disorder characterized by a persistent pattern of inattention and/or hyperactivity.

ADHESION. The joining or sticking together of parts of an organ that are not normally joined together.

ADIPOSE TISSUE. Fat tissue.

ADJUNCTIVE. Refers to a form of treatment that is not strictly necessary to a therapy regimen but is helpful. Music therapy is an example of an adjunctive form of treatment.

ADJUSTMENT. A specific type of manipulation of the spine designed to return it to proper structural and functional form.

ADJUSTMENT DISORDER. A disorder defined by the development of significant emotional or behavioral symptoms in response to a stressful event or series of events within the normal range of human experience.

ADJUVANT. A substance added to a vaccine to increase the immune system's response to the vaccine contents.

ADJUVANT CHEMOTHERAPY. Treatment of the tumor with drugs after surgery to kill as many of the remaining cancer cells as possible.

ADJUVANT THERAPY. Treatment involving radiation, chemotherapy (drug treatment), hormone therapy, biotherapeutics, or a combination of any of these given after the primary treatment in order to rid the body of residual microscopic cancer.

ADRENAL CORTEX. The outer tissue of the adrenal gland. It produces a group of chemically related hormones called corticosteroids that control mineral and water balance in the body and include aldosterone and cortisol.

ADRENAL GLAND. An endocrine gland located above each kidney. The inner part of each gland secretes epinephrine (adrenaline) and the outer part secretes steroid hormones.

ADRENAL MEDULLA. The inner part of the adrenal gland. The adrenal medulla produces the hormones epinephrine (adrenaline), which stimulates the heart, tightens blood vessels, and relaxes some smooth muscles; and norepinephrine, which has similar effects.

ADRENALS. Glands on top of the kidneys that produce four different types of hormones.

ADRENERGIC. Refers to neurons (nerve cells) that use catecholamines as neurotransmitters at a synapse.

ADRENERGIC RECEPTOR. There are three families of adrenergic receptors, alpha$_1$, alpha$_2$ and beta, and each family contains three distinct subtypes. Each of the nine subtypes are coded by separate genes, and display specific drug specificities and regulatory properties.

ADRENOCORTICOTROPIC HORMONE (ACTH). A pituitary hormone that stimulates the cortex of the adrenal glands to produce adrenal cortical hormones.

ADRENOCORTICOTROPIN (CORTICOTROPHIN). A hormone that acts on cells of the adrenal cortex, causing them to produce male sex hormones and hormones that control water and mineral balance in the body.

ADSORPTION. A process that occurs when molecules of a liquid or gas cling to the surface of a solid.

ADVANCED BREAST BIOPSY INSTRUMENT (ABBI). Uses a rotating circular knife and thin heated electrical wire to remove a large cylinder of abnormal breast tissue.

AEROBIC BACTERIA. Bacteria that require oxygen in order to grow and survive.

AEROBIC EXERCISE. Any exercise that increases the body's oxygen consumption and improves the functioning of the cardiovascular and respiratory systems.

AEROSOLS. Sprays that contain propellants and solvents, including many household products.

AFFECT. An observed emotional expression or response.

AFFECTIVE DISORDER. An emotional disorder involving abnormal highs and/or lows in mood.

AFFECTIVE FLATTENING. A loss or lack of emotional expressiveness. It is sometimes called blunted or restricted affect.

AFFERENT. Refers to peripheral nerves that transmit signals to the spinal cord and the brain. These nerves carry out sensory function.

AFLATOXINS. A group of naturally occurring toxins produced by fungi of the genus *Aspergillus*.

AFP (ALPHA-FETOPROTEIN). A tumor marker associated with liver, testicular, and ovarian cancer.

AFRICAN ENDEMIC KAPOSI'S SARCOMA. A form of KS that affects men and boys and that can appear like classic KS or in a more lethal form.

AGAMMAGLOBULINEMIA. The lack of gamma globulins in the blood. Antibodies are the main gamma globulins of interest, so this term means a lack of antibodies.

AGAR. A gel made from red algae that is used to culture certain disease agents in the laboratory.

AGAVE NECTAR. A sweetener produced commercially in Mexico from the leaves of the agave, a succulent plant with thick fleshy leaves.

AGE-RELATED MACULAR DEGENERATION (ARMD). Degeneration of the macula (the central part of the retina where the rods and cones are most dense) that leads to loss of central vision in people over 60 years of age.

AGGLUTININ. An antibody that causes particulate antigens such as bacteria or other cells to clump together.

AGGRAVATED SEXUAL ABUSE. When an individual is forced to submit to sexual acts by use of physical force; threats of death, injury, or kidnapping; or substances that render that individual unconscious or impaired.

AGGREGATION. The blood cell clumping process that is measured in the platelet aggregation test.

AGITATION. Excessive restlessness or emotional disturbance that is often associated with anxiety or psychosis; common in middle-stage AD.

AGNOSIA. The inability to recognize familiar people, places, and objects.

AGONIST. A chemical that is added to the blood sample in the platelet aggregation test to stimulate the clumping process.

AGORAPHOBIA. An intense fear of being trapped in a crowded, open, or public space where it may be hard to escape, combined with the dread of having a panic attack.

AGRANULOCYTOSIS. An acute condition marked by severe depression of the bone marrow, which produces white blood cells, and by prostration, chills, swollen neck, and sore throat sometimes with local ulceration. Aalso called agranulocytic angina or granulocytopenia.

AIDS. Acquired immune deficiency syndrome. A disease caused by infection with the human immunodeficiency virus (HIV). In people with this disease, the immune system breaks down, increasing vulnerability to other infections and some types of cancer.

AIDS DEMENTIA COMPLEX. A type of brain dysfunction caused by HIV infection that causes difficulty thinking, confusion, and loss of muscular coordination.

AIDS–RELATED KAPOSI'S SARCOMA. A form of KS that emerged as one of the first illnesses associated with AIDS patients. Tumors usually appear on the upper body, the soft palate and gum areas, and, as the disease advances, in the lymph nodes, stomach, intestines, and lungs.

AKATHISIA. Agitated or restless movement, usually affecting the legs and accompanied by a sense of discomfort. It is a common side effect of neuroleptic medications.

ALBINISM. A genetic disease characterized by the absence of the normal skin pigment, melanin.

ALBINO. A person or animal lacking normal coloring in the eyes, hair, and skin due to a hereditary inability to produce the skin pigment melanin. The condition itself is called albinism.

ALBUMIN. A blood protein that is made in the liver and helps to regulate water movement in the body.

ALCOHOL USE DISORDERS INVENTORY TEST (AUDIT). A test for alcohol use developed by the World Health Organization (WHO). Its ten questions address three specific areas of drinking over a 12–month period: the amount and frequency of drinking, dependence upon alcohol, and problems that have been encountered due to drinking alcohol.

ALDOLASE. An enzyme, found primarily in the muscle, that helps convert sugar into energy.

ALDOLASE B. Also called fructose 1-phosphate aldolase, this chemical is produced in the liver, kidneys, and brain. It is needed for the breakdown of fructose, a sugar found in fruits, vegetables, honey, and other sweeteners.

ALDOSTERONE. A hormone produced in the cortex of the adrenal gland that increases the reabsorption of sodium and water and the release of potassium in the kidneys.

ALDOSTERONISM. A condition defined by high serum levels of aldosterone, a hormone secreted by the adrenal gland that is responsible for increasing sodium reabsorption in the kidneys.

ALEXANDER TECHNIQUE. A technique developed by Frederick Alexander that focuses on the variations in body posture, muscles, and breathing. Defects in these functions can lead to stress, nervous tension or possible loss of function.

ALGAE. Plants that have one cell.

ALKALINE. A solution is considered alkaline if it contains fewer hydrogen atoms than pure water.

ALKALINE PHOSPHATASE. An enzyme found throughout the body, primarily in liver, bone, placenta, and intestine.

ALKALOID. A bitter organic base, such as caffeine or morphine, that contains nitrogen and usually oxygen, often occurs in plant seeds, and usually has physiological activity.

ALKALOSIS. A condition of the blood and other body fluids in which bicarbonate levels are higher than normal.

ALKYLATING AGENT. A chemical that alters the composition of the genetic material of rapidly dividing cells, such as cancer cells, causing selective cell death; used as a chemotherapeutic agent to treat B-CLL.

ALLERGEN. A foreign substance, such as mites in house dust or animal dander which, when inhaled, causes the airways to narrow and produces symptoms of asthma.

ALLERGENIC. Acting as an allergen or inducing an allergic response.

ALLERGIC REACTION. An immune system reaction to a substance in the environment; symptoms include rash, inflammation, sneezing, itchy watery eyes, and runny nose.

ALLERGIC RHINITIS. Inflammation of the mucous membranes of the nose and eyes in response to an allergen. Hay fever is seasonal allergic rhinitis.

ALLERGY. Altered body reaction, usually hypersensitivity, as a response to exposure to a specific substance.

ALLEVIATE. To make something easier to be endured.

ALLOGENEIC. Referring to bone marrow transplants between two different, genetically dissimilar people.

ALLOGRAFT. Tissue that is taken from one person's body and grafted to another person.

ALLOPATHIC. Pertaining to conventional medical treatment of disease symptoms that uses substances or techniques to oppose or suppress the symptoms.

ALLOPATHY. Conventional medical treatment of disease symptoms that uses substances or techniques to oppose or suppress the symptoms.

ALLOPURINOL. A drug that corrects hyperuricemia by inhibiting urate production.

ALOE VERA. An extract from the plant *Aloe barbadensis* that is used in skin creams and for treating burns.

ALOPECIA. The medical term for baldness.

ALPHA BLOCKERS. Medications that bind alpha adrenergic receptors and decrease the workload of the heart and lower blood pressure. They are commonly used to treat hypertension, peripheral vascular disease, and hyperplasia.

ALPHA-2 AGONIST. A class of drugs that bind to and stimulate alpha-2 adrenergic receptors, causing responses similar to those of adrenaline and noradrenaline, by inhibiting aqueous humor production.

ALPHA-FETOPROTEIN. A substance produced by a fetus' liver that can be found in the amniotic fluid and in the mother's blood. Abnormally high levels of this substance suggests there may be defects in the fetal neural tube, a structure that will include the brain and spinal cord when completely developed. Abnormally low levels suggest the possibility of Down' syndrome.

ALPHA-FETOPROTEIN TEST. A blood test that can be done after the sixteenth week of pregnancy to evaluate the possibility of spina bifida and other birth defects in the fetus.

ALPHA-INTERFERON. A natural body substance that now can be made in large quantities and is an effective treatment for some types of viral inflammatory disease, including hepatitis C.

ALPHA-THALASSEMIA. An inherited disorder that interferes with the normal production of hemoglobin.

ALPROSTADIL. A smooth muscle relaxant sometimes injected into the penis or applied to the urethral opening to treat impotence.

ALTER. An alternate or secondary personality in a patient with Dissociative Identity Disorder (DID).

ALTERNATING CURRENT (AC). An electric current in which the flow of the electric charge periodically reverses direction. AC is the form in which electricity is usually delivered to homes. The usual household wall outlet (120 volts) provides a current with 120 reversals of the direction of flow occurring each second and is termed 60-cycle alternating current.

ALTERNATIVE THERAPY. A therapy is generally called alternative when it is used instead of conventional treatments.

ALTITUDE SICKNESS. A set of symptoms that people who normally live at low altitudes may have when they travel to high altitudes. The symptoms include nosebleed, nausea, and shortness of breath.

ALVARADO SCORE. A ten-point scoring system used by doctors to evaluate the likelihood that a patient has acute appendicitis.

ALVEOLI (SINGULAR, ALVEOLUS). Small spherical sacs at the ends of the bronchioles in the lungs in which blood gases are exchanged.

ALYKYLATING DRUG. A drug that kills cells by directly damaging DNA.

ALZHEIMER'S DISEASE. A progressive, neurodegenerative disease characterized by loss of function and death of nerve cells in several areas of the brain, leading to loss of mental functions such as memory and learning.

AMALGAM. A mixture of metals, primarily mercury used to make large, durable fillings. Also called silver fillings.

AMBIENT. Surrounding.

AMBLYOPIA. Decreased visual acuity, usually in one eye, in the absence of any structural abnormality in the eye; often called lazy eye.

AMBULATION. Moving from place to place.

AMBULATORY MONITORING. ECG recording over a prolonged period during which the patient can move around.

AMEBIASIS. An infection caused by an ameba, which is a type of protozoan.

AMEBOMA. A mass of tissue that can develop on the wall of the colon in response to amebic infection.

AMENORRHEA. Abnormal cessation of menstruation.

AMINO ACID. An organic compound composed of both an amino group and an acidic carboxyl group; amino acids are the basic building blocks of proteins.

AMINOACIDURIA. The abnormal presence of amino acids in the urine.

AMNESIA. A general medical term for loss of memory that is not due to ordinary forgetfulness. Amnesia can be caused by head injuries, brain disease, or epilepsy as well as by dissociation.

AMNESIC. Relating to amnesia, the loss of memory.

AMNIOCENTESIS. A procedure in which a needle is inserted through a pregnant woman's abdomen and into her uterus to withdraw a small sample of amniotic fluid. The amniotic fluid can be examined for sign of disease or other problems afflicting the fetus.

AMNIOTIC BAND. An abnormal condition of fetal development in which fibrous bands of tissue develop out of the amniotic sac. The bands encircle and constrict parts of the baby's body, interfering with normal development and sometimes causing congenital amputation.

AMNIOTIC FLUID. Fluid within the uterine sac in which the fetus lives until born.

AMNIOTIC MEMBRANE. The thin tissue that creates the walls of the amniotic sac.

AMNIOTIC SAC. The membranous sac that surrounds the embryo and fills with watery fluid as pregnancy advances.

AMOEBA. A type of protozoa (one-celled animal) that can move or change its shape by extending projections of its cytoplasm.

AMPERAGE. A measurement of the amount of electric charge passing a given point per unit time. One ampere represents about 6.241×10^{18} electrons passing a given point in a wire in one second of time.

AMPHETAMINES. Sympathomimetic amines; sometimes called speed; synthetic chemicals that stimulate the central nervous system.

AMPHOTERICIN B (FENGIZONE). An antifungal medication, prescribed for topical or systemic use in treating fungal infections.

AMPLIFICATION. A process by which something is made larger. In clotting, only a very few chemicals are released by the initial injury; they result in a cascade of chemical reactions which produces increasingly larger quantities of different chemicals, resulting in an appropriately sized, strong fibrin clot.

AMPULLA OF VATER. The widened portion of the duct through which bile and pancreatic juices enter the intestine. Ampulla is a Latin word for a bottle with a narrow neck that opens into a wide body.

AMPUTATION. Surgical removal of a limb.

AMYGDALA. An almond-shaped brain structure of the limbic system that is activated in stressful situations and triggers fear.

AMYLASE. A digestive enzyme that breaks down starch.

AMYLOID PLAQUE. A waxy, translucent substance composed of complex protein fibers and polysaccharides that forms in body tissues in some degenerative diseases, such as Alzheimer s disease.

AMYLOIDOSIS. Accumulation of amyloid deposits in various organs and tissues in the body such that normal functioning of an organ is compromised.

AMYLOPHAGIA. The compulsive eating of purified starch, typically cornstarch or laundry starch.

ANABOLIC. Causing muscle and bone growth and a shift from fat to muscle in the body.

ANABOLIC STEROID. Drugs derived from the male sex hormones that increase the rate of tissue growth. They are best known for increasing the rate of muscle development.

ANAEROBIC BACTERIA. Bacteria that can grow and reproduce in an oxygen-free environment.

ANAGRELIDE. An orphan drug that is approved for treating Polycythemia vera patients on an investigational basis. Anagrelide works by controlling the level of platelets in the blood.

ANAL FISSURE. An ulcer on the margin of the anus.

ANAL SPHINCTER MUSCLES. Muscles that control the opening and closing of the anus.

ANALGESIA. A state of insensitivity to pain even though the person remains fully conscious.

ANALGESIC. A medication that relieves pain without causing loss of consciousness. Over–the–counter analgesics include aspirin and NSAIDs.

ANALOGUE. A drug that is similar to the drug from which it is derived.

ANALYSAND. A person undergoing psychoanalysis.

ANAPHYLAXIS. Also called anaphylactic shock; a severe allergic reaction characterized by airway constriction, tissue swelling, and lowered blood pressure.

ANASTOMOSIS. Surgical re-connection of the ends of the bowel after removal of a portion of the bowel.

ANATOMIC. Related to the physical structure of an organ or organism.

ANATOMY. The science of the body structure of an organism and its parts.

ANDROGENIC. Causing testosterone-like, masculinizing effects.

ANDROGENS. A class of chemical compounds (hormones) that stimulates the development of male secondary sexual characteristics.

ANDROSTENEDIONE. Also called ''andro,'' this hormone occurs naturally during the making of testosterone and estrogen.

ANEMIA. A blood condition in which the level of hemoglobin or the number of red blood cells falls below normal values. Common symptoms include paleness, fatigue, and shortness of breath.

ANEMIA OF CHRONIC DISEASE (ACD). Blood disorder that results from a medical condition that affects the production and lifespan of red blood cells.

ANENCEPHALY. Congenital absence of the brain. Occurs during the first month of embryonic development.

ANESTHESIA. A condition created by drugs that produces a numb feeling. General anesthesia produces unconsciousness whereas a local anesthesia produces numbness around the site where the drug was introduced.

ANESTHESIOLOGIST. A physician who has special training and expertise in the delivery of anesthetics.

ANESTHETIC. A drug that causes loss of sensation. It is used to lessen the pain of surgery and medical procedures.

ANEUPLOID. An abnormal number of chromosomes in a cell.

ANEURYSM. A pouchlike bulging of a blood vessel. Aneurysms can rupture, leading to stroke.

ANGINA. A condition in which lack of blood to the heart causes severe chest pain.

ANGINA PECTORIS. A feeling of tightness, heaviness, or pain in the chest, caused by a lack of oxygen in the muscular wall of the heart.

ANGIOEDEMA. An allergic skin disease characterized by patches of confined swelling involving the skin the layers beneath the skin, the mucous membranes, and sometimes the viscera—called also angioneurotic edema, giant urticaria, Quincke's disease, or Quincke's edema.

ANGIOGENESIS. The formation of new blood vessels, for example, as a result of a tumor.

ANGIOGRAM. An x-ray (radiographic) study of the blood vessels. An angiogram uses a radiopaque substance, or contrast medium, to make the blood vessels visible under x ray.

ANGIOGRAPHY. A mapping of the brain's blood vessels, using x-ray imaging.

ANGIOID STREAKS. Gray, orange, or red wavy branching lines in Bruch's membrane.

ANGIOMA. A tumor (such as a hemangioma or lymphangioma) that mainly consists of blood vessels or lymphatic vessels.

ANGIOMATOUS MALFORMATIONS. Tumors in blood vessels.

ANGIOPLASTY. A medical procedure in which a catheter, or thin tube, is threaded through blood vessels. The catheter is used to place a balloon or stent (a small metal rod) at an area of stenosis and expand it mechanically.

ANGIOSPASM. Spasmodic contraction of a blood vessel with increase in blood pressure.

ANGIOTENSIN-CONVERTING ENZYME (ACE) INHIBITOR. A drug that lowers blood pressure by interfering with the breakdown of a protein-like substance involved in blood pressure regulation.

ANION. An ion carrying a negative charge owing to a surplus of electrons. Anions in the body include bicarbonate, chloride, phosphate, sulfate, certain organic acids, and certain protein compounds.

ANISOMETROPIA. An eye condition in which there is an inequality of vision between the two eyes. There may be unequal amounts of nearsightedness, farsightedness, or astigmatism, so that one eye will be in focus while the other is not.

ANKLE-BRACHIAL INDEX (ABI) TEST. A means of checking the blood pressure in the arms and ankles using a regular blood pressure cuff and a special ultrasound stethoscope (Doppler). The pressure in the ankle is compared to the pressure in the arm.

ANKYLOSING. When bones of a joint are fused, stiff, or rigid.

ANKYLOSING SPONDYLITIS. A type of arthritis that causes gradual loss of flexibility in the spinal column. It occurs most commonly in males between 16 and 35.

ANODE. The positive electrode to which an electromagnetic current flows.

ANOGENITORECTAL SYNDROME. Another name for third-stage LGV.

ANOMIC APHASIA. A condition characterized by either partial or total loss of the ability to recall the names of persons or things as a result of a stroke, head injury, brain tumor, or infection.

ANOREXIA NERVOSA. A disorder of the mind and body in which people starve themselves in a desire to be thin, despite being of normal or below normal body weight for their size and age.

ANORGASMIA. A sexual dysfunction characterized by the inability to achieve orgasm.

ANOVULATION. The absence of ovulation.

ANOVULATORY BLEEDING. Bleeding without release of an egg from an ovary.

ANOXEMIA. An extreme lack of oxygen in the blood.

ANOXIA. An absence of oxygen.

ANTACIDS. Substances that counteract or neutralize acidity. They act promptly and have short durations of actions.

ANTAGONIST. A substance that tends to nullify the action of another.

ANTEPARTUM. This refers to the time period of the woman's pregnancy from conception and onset of labor.

ANTHELMINTHIC (ALSO SPELLED ANTHELMINTIC). A type of drug or herbal preparation given to destroy parasitic worms or expel them from the body.

ANTHRAX. An infectious disease caused by a type of bacterium. The disease can be passed from animals to people and usually is fatal. Symptoms include sores on the skin.

ANTHROPOLOGY. The study of the origins, biological characteristics, beliefs, and social customs of human beings.

ANTIANDROGEN. A substance that blocks the action of androgens, the hormones responsible for male characteristics. Used to treat prostate cancers that require male hormones for growth.

ANTIBIOTIC. A drug used to treat infections caused by bacteria and other microorganisms.

ANTIBIOTIC RESISTANCE. The ability of infectious agents to change their biochemistry in such a way as to make an antibiotic no longer effective.

ANTIBODY. A blood protein produced in response to a specific foreign substance including bacteria, viruses, and parasites; the antibody destroys the organism, providing protection against disease.

ANTI-CHOLINERGIC DRUG. A medication that blocks or subdues the action of the neurotransmitter acetylcholine.

ANTICOAGULANT. A chemical or medication that prevents blood from clotting.

ANTICONVULSANTS. A class of drugs given to control seizures.

ANTIDEPRESSANT. A medication used to relieve the symptoms of clinical depression.

ANTIDIURETIC HORMONE (ADH); VASOPRESSIN. A polypeptide hormone that is secreted by the pituitary gland along with oxytocin, or is chemically

synthesized, and which suppresses water loss and increases blood pressure.

ANTIDOTE. A remedy to counteract unwanted effects from medications or poisons.

ANTIEMETIC. A drug that helps stop nausea and vomiting.

ANTIFUNGAL. A medicine used to treat infections caused by a fungus.

ANTIGEN. A foreign protein or particle that causes the body to produce specific antibodies that bind to it.

ANTIGEN PRESENTING CELL. A cell of the immune system that ingests antigens and exposes them to cells of the immune system in a way that activates the cells to seek out and destroy any other cells displaying that antigen.

ANTIHISTAMINE. A drug that inhibits the actions of histamine. Histamine causes dilatation of capillaries, contraction of smooth muscle, and stimulation of gastric acid secretion.

ANTI-INFLAMMATORY DRUGS. A class of drugs that lower inflammation and that includes NSAIDs and corticosteroids.

ANTIMETABOLITE. A drug that interferes with a cell's growth or ability to multiply.

ANTIMICROBIAL AGENT. A substance that kills microorganisms such as bacteria or mold, or stops them from growing and causing disease.

ANTI-MOTILITY MEDICATIONS. Medications such as loperamide (Imodium), dephenoxylate (Lomotil), or medications containing Codeine or narcotics that decrease the ability of the intestine to contract. This can worsen the condition of a patient with dysentery or colitis.

ANTIMYOCARDIAL ANTIBODY. An autoantibody that attacks a person's own heart muscle, or myocardium.

ANTINEOPLASTICS. Agents that inhibit or prevent the development, maturation, and proliferation of malignant cells.

ANTINUCLEAR ANTIBODIES. Autoantibodies that attack substances found in the center, or nucleus, of all cells.

ANTINUCLEAR ANTIBODY (ANA) TEST. A test often used to look for autoantibodies that react against components of the nucleus of the body's cells. Many people with lupus test positive for ANA.

ANTIOXIDANT. A molecule that prevents oxidation. In the body, antioxidants attach to other molecules called free radicals and prevent the free radicals from causing damage to cell walls, DNA, and other parts of the cell.

ANTIPLATELET DRUG. Drug that inhibits platelets from aggregating to form a plug. They are used to prevent clotting and alter the natural course of atherosclerosis.

ANTIPSYCHOTICS. Drugs used to treat psychotic conditions such as schizophrenia or psychosis. These medications are powerful tranquilizers that all have sedating and calming effects, but their major effect is to reduce psychotic thinking and behavior.

ANTIPYRETIC. A drug that lowers fever, like aspirin or acetaminophen.

ANTISEPTIC. Chemicals applied to the skin to destroy bacteria and prevent infection.

ANTISOCIAL PERSONALITY. A personality characterized by attitudes and behaviors at odds with society's customs and moral standards, including illegal acts.

ANTITHROMBIC. Preventing clot formation.

ANTITOXIN. A substance that inactivates a poison (e.g., toxin) and protects the body from being injured by it.

ANTITUSSIVES. Drugs used to suppress coughing.

ANTIVIRAL. Refers to a drug that can destroy viruses and help treat illnesses caused by them.

ANTRECTOMY. A surgical procedure for ulcer disease in which the antrum, a portion of the stomach, is removed.

ANUS. The canal at the end of the large intestine through which waste is excreted to the outside of the body.

ANXIETY. An abnormal and overwhelming sense of apprehension and fear often marked by physiological signs (as sweating, tension, and increased pulse), by doubt concerning the reality and nature of the threat, and by self-doubt about one's capacity to cope with it.

ANXIETY DISORDER. The experience of prolonged, excessive worry about circumstances in one's life that is severe enough to disrupt daily life.

ANXIOLYTIC. A type of medication that helps to relieve anxiety.

AORTA. The largest artery in the body, arising from the left ventricle (lower chamber) of the heart and extending down into the abdomen.

AORTIC ANEURYSMS. Occurs when an area in the aorta (the main artery of the heart) is weakened and bulges like a balloon.

AORTIC DISSECTION. A tear in the aorta (the main blood vessel carrying away from the heart) that allows blood to flow between layers of the aorta, eventually causing it to fail.

AORTIC STENOSIS. A stiffening of the artery which carries blood from the heart to the body.

AORTIC VALVE. The valve between the heart's left ventricle and ascending aorta that prevents regurgitation of blood back into the left ventricle.

APANA. Life sustaining energy centered in the larger intestine; the fifth of the five airs of Ayurvedic philosophy; the life force governing expulsion activity.

APHAKIA. Absence of the lens of the eye.

APHASIA. The loss of the ability to speak, or to understand written or spoken language. A person who cannot speak or understand language is said to be aphasic.

APHERESIS. A procedure in which whole blood is withdrawn from a donor, a specific blood component is separated and collected, and the remainder is reinfused into the patient.

APHTHOUS STOMATITIS. A specific type of stomatitis presenting with shallow, painful ulcers. Also known as *canker sores*.

APICAL. Rounded end of the root of a tooth that is embedded in hard tissue (bone); toward the apex of the root.

APICOECTOMY. Also called root resectioning. The root tip of a tooth is accessed in the bone and a small amount is shaved away. The diseased tissue is removed and a filling is placed to reseal the canal.

APLASTIC. Exhibiting incomplete or faulty development.

APLASTIC ANEMIA. A disorder in which the body produces inadequate amounts of red blood cells and hemoglobin due to underdeveloped or missing bone marrow.

APNEA. A cessation of breathing.

APOLIPOPROTEIN E (APOE). A protein that transports cholesterol throughout the body. One form of this protein, APOE e4, is associated with a 60% risk of late-onset AD.

APOPTOSIS. Cell death.

APOXIA. Altitude sickness.

APPENDECTOMY. Surgical removal of the appendix.

APPENDICITIS. Condition characterized by the rapid inflammation of the appendix, a part of the intestine.

APPENDIX (PLURAL, APPENDICES). The finger-shaped pouch attached to the cecum, the beginning of the large intestine.

APPERCEPTION. The process of understanding through linkage with previous experience.

APPETITE SUPPRESSANT. A drug that reduces appetite.

APRAXIA. Impairment of the ability to make purposeful movements, but not paralysis or loss of sensation.

AQUEOUS HUMOR. A transparent liquid, contained within the eye, that is composed of water, sugars, vitamins, proteins, and other nutrients.

ARACHNODACTYLY. A condition characterized by abnormally long and slender fingers and toes.

ARACHNOID MATER. One of three membranes that encase the brain and spinal cord. The arachnoid mater is the middle membrane.

ARC FLASH. A type of electrical explosion resulting from electrical breakdown of the gases in air, which normally does not conduct electricity. Arc flashes can occur where there is sufficient voltage in an electrical system and a path to the ground or to lower voltage.

AREOLA. The area of pigmented skin surrounding the human nipple in both males and females. It is roughly circular in shape.

ARGON. A colorless, odorless gas.

AROMATHERAPY. The therapeutic use of plant-derived, aromatic essential oils to promote physical and psychological well-being.

ARREST. A sudden stopping of the function of a body organ, such as no breathing (respiratory arrest) or no beating of the heart (cardiac arrest).

ARRHYTHMIA. A variation in the normal rhythm of the heart beat. Atrial fibrillation and flutter are two types of arrhythmia.

ARTEMINISININS. A family of antimalarial products derived from an ancient Chinese herbal remedy. Two of the most popular varieties are artemether and artesunate, used mainly in southeast Asia in combination with mefloquine.

ARTERIAL BLOOD GASES TEST. A test to analyze blood for oxygen, carbon dioxide, and bicarbonate content, as well as blood pH (acidity level). Used to test the effectiveness of respiration.

ARTERIAL EMBOLISM. A blood clot arising from another location that blocks an artery.

ARTERIES. Blood vessels that carry blood away from the heart to the cells, tissues, and organs of the body.

ARTERIOGRAM. A diagnostic test that involves viewing the arteries and/or attached organs by injecting a contrast medium or dye, into the artery and taking an x ray.

ARTERIOGRAPHY. A medical test in which an x-ray visible dye is injected into blood vessels. This dye allows the blood vessels to be imaged with x rays.

ARTERIOLES. Small blood vessels that carry arterial (oxygenated) blood.

ARTERIOSCLEROSIS. A chronic condition characterized by thickening and hardening of the arteries and the build-up of plaque on the arterial walls. Arteriosclerosis can slow or impair blood circulation.

ARTERIOVENOUS MALFORMATION. An abnormal tangle of arteries and veins in which the arteries feed directly into the veins without a normal intervening capillary bed.

ARTERITIS. Inflammation of an artery.

ARTERY. A blood vessel that carries blood away from the heart to peripheral tissues.

ARTHEROSCLEROTIC PLAQUE. A deposit of fatty and calcium substances that accumulate in the lining of the artery wall, restricting blood flow.

ARTHRALGIA. Sharp, severe pain, extending along a nerve or group of nerves, experienced in a joint and/or joints.

ARTHRITIS. A condition characterized by inflamed, swollen, painful joints.

ARTHROCENTESIS. A procedure in which the doctor inserts a needle into the patient's joint to withdraw fluid for diagnostic testing or to drain infected fluid from the joint.

ARTHROCHALASIA. Excessive loosness of the joints.

ARTHROGRAPHY. An imaging technique used to evaluate joints. Dye is injected into a joint and then x rays are taken; areas where the dye leaks out may indicate an injury.

ARTHROPLASTY. The surgical reconstruction or replacement of a joint.

ARTHROPODS. A phylum name referring to certain insects (including mosquitoes and ticks) and spiders.

ARTHROSCLEROSIS. A condition where fatty deposits cause the arteries to narrow.

ARTHROSCOPE. An instrument for the visual examination of the interior of a joint.

ARTHROSCOPIC KNEE SURGERY. Surgery performed to examine or repair tissues inside the knee joint through a special scope (arthroscope).

ARTHROSCOPY. Examination of a joint with an arthroscope or joint surgery using an arthroscope.

ARTICULAR BONES. Two or more bones connected to each other via a joint.

ARTICULAR CAPSULE. An envelope of tissue that surrounds a free moving joint, composed of an external layer of white fibrous tissue and an external synovial membrane that secretes a lubricant into the joint.

ARTICULATION. The ability to pronounce a word correctly. A lisp is an example of an articulation problem.

ASANA. A position or stance in yoga.

ASBESTOS. A silicate (containing silica) mineral that occurs in a variety of forms; it is characterized by a fibrous structure and resistance to fire.

ASCITES. Abnormal accumulation of fluid in the abdomen, making the abdomen appear distended.

ASCORBIC ACID. Another term for vitamin C, a nutrient found in fresh fruits and vegetables. Good sources of vitamin C in the diet are citrus fruits like oranges, lemons, limes, and grapefruits, berries, tomatoes, green peppers, cabbage, broccoli, and spinach.

ASEPTIC. Sterile; containing no microorganisms, especially no bacteria.

ASEPTIC MENINGITIS. A term that is sometimes used for meningitis that is not caused by bacteria.

ASHERMAN'S SYNDROME. The cessation of menstruation and/or infertility caused by intrauterine adhesions.

ASPERGER SYNDROME. Characterized by autistic-type behavior but no problems with language and no clinically significant cognitive delay.

ASPERGILLOMA. A ball or mass made of *Aspergillus* fungi that can form in the lungs of patients with suppressed immune systems.

ASPERGILLOSIS. A lung infection caused by the mold *Aspergillus fumigatus*.

ASPHYXIA. Lack of oxygen.

ASPHYXIATION. Oxygen starvation of tissues.

ASPIRATION. A procedure in which pus or other fluid is removed from a body cavity through a hollow needle connected to a syringe.

ASPIRATOR. A medical instrument that uses suction to withdraw fluids from the lungs, digestive tract, or other parts of the body for laboratory testing.

ASPIRIN. A derivative of salicylic acid used to relieve pain and fever.

ASSAY. An analysis of the chemical composition or strength of a substance.

ASSISTED SUICIDE. A form of self-inflicted death in which individuals voluntarily bring about their own death with the help of another, usually a physician, relative, or friend. Assisted suicide is sometimes called physician-assisted death (PAD).

ASTHENIA. Muscle weakness.

ASTHMA. A lung condition, usually of allergic origin, in which the airways become narrow due to smooth muscle contraction, causing wheezing, coughing, and shortness of breath.

ASTIGMATISM. A condition in which one or both eyes cannot filter light properly and images appear blurred and indistinct.

ASYMMETRIC. Not occurring equally on both sides of the body.

ASYMPTOMATIC. Persons who carry a disease and are usually capable of transmitting the disease but who do not exhibit symptoms of the disease are said to be asymptomatic.

ATAXIA. A deficiency of muscular coordination, especially when voluntary movements are attempted, such as grasping or walking.

ATHERECTOMY. A non-surgical technique for treating diseased arteries with a rotating device that cuts or shaves away obstructing material inside the artery.

ATHEROSCLEROSIS. A disorder in which plaques of cholesterol, lipids, and other debris build up on the inner walls of arteries, narrowing them.

ATHEROSCLEROTIC DISEASE. The progressive narrowing and hardening of the arteries over time.

ATHEROSCLEROTIC PLAQUE. A deposit of fat and other substances that accumulate in the lining of the artery wall.

ATHETOSIS. A condition marked by slow, writhing, involuntary muscle movements.

ATHLETE'S FOOT. A fungal infection between the toes, officially known as tinea pedis.

ATMOSPHERE. A measurement of pressure. One atmosphere equals the pressure of air at sea level (14.7 pounds per square inch [psi]).

ATOPIC DERMATITIS. An intensely itchy inflammation often found on the face of people prone to allergies. In infants and early childhood, it is called infantile eczema.

ATOPY. Genetic predisposition toward the development of allergies.

ATRESIA. A congenital defect in which the blood pumped through the body has too little oxygen. In tricuspid atresia, the baby lacks a triscupid valve. In pulmonary atresia, a pulmonary valve is missing.

ATRIA (SINGULAR, ATRIUM). The right and left upper chambers of the heart.

ATRIAL. Having to do with the upper chambers of the heart.

ATRIAL FIBRILLATION. A condition in which the upper chamber of the heart quivers instead of pumping in an organized way.

ATRIAL FLUTTER. A rapid pulsation of the upper chamber of the heart that interferes with normal function.

ATRIOVENTRICULAR NODE (AV NODE). Highly specialized area of the heart muscle which transmits electrical impulses.

ATRIUM (PLURAL ATRIA). The right or left upper chamber of the heart.

ATROPHY. A progressive wasting and loss of function of any part of the body.

ATROPINE. A poisonous alkaloid obtained from belladonna or related plants, used medically to dilate the pupils of the eyes and to stop spasms.

ATTENTION DEFICIT/HYPERACTIVITY DISORDER (ADD). A persistent pattern of inattention, hyperactivity and/or impulsiveness; the pattern is more frequent and severe than is typically observed in people at a similar level of development.

ATTENUATED. Alive but weakened; an attenuated microorganism can no longer produce disease.

ATTUNEMENT. Life energy teaching given by Reiki master to a student.

ATYPICAL ADENOMATOUS HYPERPLASIA. The overgrowth of the endometrium. This precancerous condition is estimated to progress to cancer in one third of the cases.

AUDIOGRAM. A chart or graph of the results of a hearing test conducted with audiographic equipment. The chart reflects the softest (lowest volume) sounds that can be heard at various frequencies or pitches.

AUDIOLOGIST. A person with a degree and/or certification in the areas of identification and measurement of hearing impairments and rehabilitation of those with hearing problems.

AUDITORY. Relating to the sense of the organs of hearing.

AURA. A group of visual or other sensations that precedes the onset of a migraine attack.

AURICLE. The external structure of the ear.

AURICULAR ACUPUNCTURE. Acupuncture using only points found on the ears.

AUSCULTATION. The process of listening to sounds that are produced in the body. Direct auscultation uses the ear alone, such as when listening to the grating of a moving joint. Indirect auscultation involves the use of a stethoscope to amplify the sounds from within the body, like a heartbeat.

AUTISM. A severe developmental disorder that usually begins before three years of age and affects a child's social as well as intellectual development. Some researchers theorized that immunization with the MMR vaccine was a risk factor for autism.

AUTISTIC PSYCHOPATHY. Hans Asperger's original name for Asperger syndrome. It is still used occasionally as a synonym for the disorder.

AUTOANTIBODY. An antibody produced by the body in reaction to any of its own cells or cell products.

AUTOGENIC TRAINING. A form of self-hypnosis developed in Germany that appears to be beneficial to migraine sufferers.

AUTOGRAFT. Tissue that is taken from one part of a person's body and transplanted to a different part of the same person.

AUTOHEMOTHERAPY. A form of ozone therapy in which a small quantity of the patient's blood is withdrawn, treated with a mixture of ozone and oxygen, and reinfused into the patient.

AUTOIMMUNE. Pertaining to an immune response by the body against one of its own tissues or types of cells.

AUTOIMMUNE DISORDER. A disorder in which the body's antibodies mistake the body's own tissues for foreign invaders. The immune system then attacks and causes damage to these tissues.

AUTOIMMUNE RESPONSE. A condition in which a person's immune system fails to recognize its own cells as being "self" and attacks its own body.

AUTOINFECTION. An infection caused by a disease agent that is already present in the body.

AUTOLOGOUS. A transplant where the material for the transplant comes from the individual who is also the recipient; thus, the transplant material is genetically identical to the donor's body.

AUTOLOGOUS BLOOD. The patient's own blood, drawn and set aside before surgery for use during surgery in case a transfusion is needed.

AUTOLOGOUS TRANSPLANTATION. A procedure wherein the person donates blood or tissue to themselves.

AUTOMATED EXTERNAL DEFIBRILLATOR (AED). A portable electronic device that automatically diagnoses potentially life-threatening cardiac arrhythmias (ventricular fibrillation and ventricular tachycardia) and is able to treat them through defibrillation.

AUTOMATIC THOUGHTS. Thoughts that automatically come to mind when a particular situation occurs. Cognitive-behavioral therapy seeks to challenge automatic thoughts.

AUTOMATISMS. Movements during a seizure that are semi–purposeful but involuntary.

AUTONOMIC. Refers to peripheral nerves that carry signals from the brain and that control involuntary actions in the body, such as the beating of the heart.

AUTONOMIC NERVOUS SYSTEM (ANS). The part of the nervous system that supplies nerve endings in the blood vessels, heart, intestines, glands, and smooth muscles, and governs their involuntary functioning. The autonomic nervous system is responsible for the biochemical changes involved in experiences of anxiety.

AUTOPSY. The examination of a body after death to determine the cause of death.

AUTOSOMAL. Relating to any chromosome besides the X and Y sex chromosomes. Human cells contain 22 pairs of autosomes and one pair of sex chromosomes.

AUTOSOMAL CHROMOSOME. One of the non-X or non-Y chromosomes.

AUTOSOMAL DISEASE. A disease caused by a gene mutation located on a chromosome other than a sex chromosome.

AUTOSOMAL DOMINANCE. A pattern of heredity in which a trait is inherited without respect to sex and from either parent. The hereditary diseases associated with intestinal polyps are all autosomal dominant.

AUTOSOMAL DOMINANT INHERITANCE. A pattern of inheritance in which a trait will be expressed if the gene is inherited from either parent.

AUTOSOMAL DOMINANT OR AUTOSOMAL RECESSIVE. Refers to the inheritance pattern of a gene on a chromosome other than X or Y. Genes are inherited in pairs—one gene from each parent. However, the inheritance may not be equal, and one gene may overshadow the other in determining the final form of the encoded characteristic. The gene that overshadows the other is called the dominant gene; the overshadowed gene is the recessive one.

AUTOSOMAL GENE. A gene found on one of the 22 autosomal chromosome pairs; i.e., not on a sex (X or Y) chromosome.

AUTOSOMAL RECESSIVE INHERITANCE. A pattern of genetic inheritance where two abnormal genes are needed to display the trait or disease.

AUTOSOME. A chromosome not involved in sex determination.

AVIAN CHLAMYDIOSIS. An illness in pet birds and poultry caused by *Chlamydia psittaci*. It is also known as parrot fever in birds.

AVULSION. The forcible separation of a piece of tissue from an entire structure.

AVULSION FRACTURE. A fracture caused by the tearing away of a fragment of bone where a strong ligament or tendon attachment forcibly pulls the fragment away from the bone tissue.

AXIAL. A straight line passing through a spherical body between its two poles and about which the body may revolve.

AXILLA. Armpit.

AXILLARY. Located in or near the armpit.

AXILLARY LYMPH NODE. Lymph nodes under the arm.

AXIS. A line that passes through the center of the body or body part.

AXON. A long, threadlike projection that is part of a nerve cell.

AYURVEDA MEDICINE. Ayurveda is a system of wholistic medicine from India that aims to bring the individual into harmony with nature. It provides guidance regarding food and lifestyle, so that healthy people can stay healthy and people with health challenges can improve their health.

AZOTEMIA. The presence of excess nitrogenous wastes in the blood.

B

B CELL. A type of lymphocyte or white blood cell that is derived from precursor cells in the bone marrow.

B LYMPHOCYTE. A type of lymphocyte that circulates in the blood and lymph and produces antibodies when it encounters specific antigens. B lymphocytes are also called B cells.

B VITAMINS. This family of vitamins consists of thiamine (B_1), riboflavin (B_2), niacin (B_3), pantothenic acid (B_5), pyridoxine (B_6), biotin, folic acid (B_9), and cobalamin (B_{12}). They are interdependent and involved in converting glucose to energy.

BABESIOSIS. A disease caused by protozoa of the genus *Babesia* characterized by a malaria-like fever, anemia, vomiting, muscle pain, and enlargement of the spleen. Babesiosis, like Lyme disease, is carried by a tick.

BABINSKI REFLEX. A reflex movement by the big toe when the sole is tickled: an upward response is normal in infancy, but indicates central nervous system damage in older children and adults.

BACILLUS. A rod-shaped bacterium, such as the diphtheria bacterium.

BACILLUS CALMETTE-GUÉRIN (BCG). A vaccine made from a weakened bacillus similar to the tubercle bacillus, which may help prevent serious pulmonary TB and its complications.

BACTEREMIA. An infection caused by bacteria in the blood.

BACTERIA. Single–celled microorganisms that can be seen only through a microscope. Many bacteria cause disease.

BACTERIAL OSTEOMYELITIS. An infection of the bone or bone marrow that is caused by a bacterium.

BACTERIAL VAGINITIS. This is the term for inflammation of the vagina due to a bacterial infection.

BACTERICIDAL. An agent that destroys bacteria (e.g., *Staphylococci aureus, Streptococci pneumoniae, Escherichia coli, Salmonella enteritidis*).

BACTERIURIA. The presence of bacteria in the urine.

BALANITIS XEROTICA OBLITERANS (BXO). A chronic, progressive, hardening skin inflammation of the penis.

BALLOON ANGIOPLASTY. A surgical procedure in which a balloon catheter is used to flatten plaque against an artery wall.

BAND. Immature neutrophil (a type of white blood cell).

BARBITURATES. A group of medicines that slow breathing and lower the body temperature and blood pressure. They can be habit forming and are now used chiefly for anesthesia.

BARIATRICS. The branch of medicine that deals with the prevention and treatment of obesity and related disorders.

BARIUM. A chemical used in certain radiological studies to enhance visualization of anatomical structures.

BARIUM ENEMA. An X-ray test of the bowel performed after giving the patient an enema of a white chalky substance (barium) that outlines the colon and the rectum.

BARIUM SULFATE. A barium compound used during a barium enema to block the passage of x rays during the exam.

BARIUM SWALLOW. Barium is used to coat the throat in order to take x-ray pictures of the tissues lining the throat.

BARIUM X RAY (UPPER GI). An x-ray test of the upper part of the gastrointestinal (GI) tract (including the esophagus, stomach, and a small portion of the small intestine) after the patient is given a white, chalky barium sulfate solution to drink. This substance coats the upper GI and the x rays reveal any abnormality in the lining of the stomach and the upper GI.

BAROTRAUMA. Ear pain caused by unequal air pressure on the inside and outside of the ear drum. Barotrauma, which is also called pressure–related ear pain or barotitis media, is the most common reason for myringotomies in adults.

BARRETT'S ESOPHAGUS. A precancerous condition of the esophagus that may develop as a complication of gastroesophageal reflux disease (GERD).

BARTHOLIN'S GLANDS. These glands are embedded in the vestibule of the vagina and function to maintain moisture.

BASAL CELL CANCER. The most common form of skin cancer; it usually appears as one or several nodules having a central depression. It rarely spreads (metastisizes), but is locally invasive.

BASAL GANGLIA. Brain structure at the base of the cerebral hemispheres, involved in controlling movement.

BASELINE. A return to an original state.

BASOPHIL. White blood cell that increases in response to parasitic infections and allergic reactions.

BECKER MUSCULAR DYSTROPHY (BMD). A type of muscular dystrophy that affects older boys and men, and usually follows a milder course than Duchenne muscular dystrophy.

BEHAVIOR MODIFICATION. Therapy aimed at changing behavior by substituting problem behaviors with more useful activities.

BEHAVIORAL THERAPY. Form of psychotherapy used to treat depression, anxiety disorders, phobias, and other forms of psychopathology.

BELL'S PALSY. Facial paralysis or weakness with a sudden onset, caused by swelling or inflammation of the seventh cranial nerve, which controls the facial muscles. Disseminated Lyme disease sometimes causes Bell's palsy.

BENCE-JONES PROTEIN. Light chain of an immunoglobulin that is overproduced in multiple myeloma and is excreted in the urine.

BENIGN. Mild, nonmalignant. Recovery is favorable with treatment.

BENIGN PROSTATE HYPERPLASIA (BPH). A noncancerous swelling of the prostate.

BENIGN TUMOR. An abnormal proliferation of cells that does not spread to other parts of the body.

BENZENE. A colorless volatile flammable toxic liquid hydrocarbon used as a solvent and as a motor fuel.

BENZODIAZEPINES. A class of drugs that have a hypnotic and sedative action, used mainly as tranquilizers to control symptoms of anxiety.

BERYLLIUM. A steel-grey, metallic mineral used in the aerospace and nuclear industries and in a variety of manufacturing processes.

BETA 2-MICROGLOBULIN. Protein produced by B-cells; high concentrations in the blood are indicative of multiple myeloma.

BETA BLOCKER. An anti-hypertensive (blood pressure-lowering) drug that limits the activity of epinephrine, a hormone that increases blood pressure.

BETA RADIATION. Streams of electrons emitted by beta emitters like carbon-14 and radium.

BETA-AGONIST. Beta2-agonist; beta-adrenergic agonist; a bronchodilator medication—inhaled or oral—that relaxes the muscles surrounding the airways to relieve asthma symptoms.

BETA-AMYLOID PLAQUES. Senile plaques; structures in the brain, composed of dead or dying nerve cells and cell debris surrounding deposits of beta-amyloid protein, that are diagnostic of AD. Beta-amyloid forms when amyloid precursor protein (APP) is not broken down properly.

BETA-BLOCKERS. A class of medication used to block the cellular response to chemicals normally present in the body.

BETA-HCG (BETA-HUMAN CHORIONIC GONADOTROPIN). A tumor marker associated with testicular cancer and tumors, such as choriocarcinoma and molar pregnancies, that begin in placental cells called trophoblasts.

BETA$_2$-MICROGLOBULIN. A protein found on the surface of many cells, particularly white blood cells.

BIBLIOTHERAPY. The use of books (usually self-help or problem-solving works) to improve one's understanding of personal problems and/or to heal painful feelings.

BICEPS. The muscle in the front of the upper arm.

BICUSPID. Premolar; the two-cupped tooth between the first molar and the cuspid.

BIFIDOBACTERIA. A group of bacteria normally present in the intestine.

BILATERAL. Located on or affecting both sides of the body.

BILE. A liquid secreted by the liver and passed through ducts to the small intestine where it aids in the digestion and absorption of fats.

BILE ACID. A detergent that is made in the liver and excreted into the intestine to aid in the absorption of fats.

BILE DUCTS. Tubes that carry bile, a thick yellowish-green fluid that is made by the liver, stored in the gallbladder, and helps the body digest fats.

BILIARY. Relating to the system that produces and transports bile.

BILIARY ATRESIA. The underdevelopment or absence of bile ducts.

BILIARY SYSTEM. The gall bladder and the system of tubes that carries bile from the liver into the intestine.

BILIRUBIN. A red–yellow pigment in the bile and blood; excessive accumulation of bilirubin results in jaundice.

BINGE DRINKING. Consumption of five or more alcoholic drinks in a row on a single occasion.

BINGE-EATING DISORDER. A condition characterized by uncontrolled eating.

BINOCULAR FIXATION. Both eyes pointed to and looking at the same object.

BINOCULAR VISION. Using both eyes at the same time to see an image.

BIOCHEMICAL TESTING. Measuring the amount or activity of a particular enzyme or protein in a sample of blood or urine or other tissue from the body.

BIOENERGETICS. A system of therapy that combines breathing and body exercises, psychological therapy, and the free expression of emotions to release blocked physical and psychic energy.

BIOFEEDBACK. A technique in which a person is taught to consciously control the body's response to a stimulus.

BIOFIELD HEALING. A general term for a group of alternative therapies based on the belief that the human body is surrounded by an energy field (or aura) that reflects the condition of the person's body and spirit. Rebalancing or repairing the energy field is thought to bring about healing in mind and body. Reiki, therapeutic touch, polarity balancing, Shen

therapy, and certain forms of color therapy are considered forms of biofield healing.

BIOLOGICAL CLOCK. A synonym for the body's circadian rhythm, the natural biological variations that occur over the course of a day.

BIOLOGICAL PSYCHIATRY. An approach to psychiatry that aims to understand mental disorders in terms of the biological and biochemical functions of the central nervous system.

BIOLOGICAL TISSUE VALVE. A replacement heart valve that is harvested from the patient (autograft), a human cadaver (homograft or allograft), or other animal, such as a pig (heterograft).

BIOLOGICS. A class of drugs produced by means of biological processes involving recombinant DNA technology.

BIOMARKER. A biochemical substance that can be detected in blood samples and indicates the presence of a cancerous tumor.

BIOPSY. A diagnostic procedure in which a small sample of tissue is obtained and examined under the microscope to determine they type and stage of a disease.

BIOSYNTHESIS. The manufacture of materials in a biological system.

BIOTERRORISM. The intentional use of disease-causing microbes or other biologic agents to intimidate or terrorize a civilian population for political or military reasons.

BIOTIN. A B complex vitamin, found naturally in yeast, liver, and egg yolks.

BIOTYPE. A variant strain of a bacterial species with distinctive physiological characteristics.

BIPOLAR DISORDER. A mood disorder marked by alternating episodes of extremely low mood (depression) and exuberant highs (mania). Also known as manic–depressive disorder.

BISMUTH. A substance used in medicines to treat diarrhea, nausea, and indigestion.

BISPHOSPHONATE. A class of drugs used to treat Paget's disease. These drugs bind to the minerals in bone tissue and lessen the amount of bone loss associated with Paget's disease.

BITOT'S SPOTS. Bitot's spots are superficial, foamy gray, triangular spots on the white of the eyeball.

BLACKHEAD. A plug of fatty cells capped with a blackened mass.

BLADDER. A balloon-like organ located in the lower abdomen that stores urine.

BLADDER NECK. The place where the urethra and bladder join.

BLADDER OBSTRUCTION. A blockage of the bladder caused by the presence of calculi (e.g., mineral deposits) or an anatomic abnormality.

BLADDER SPHINCTER. The outlet that releases urine into the urethra.

BLADDER TRAINING. A behavioral modification program used to treat stress incontinence. Bladder training involves putting the patient on a toilet schedule, and gradually increasing the time interval between urination.

BLASTEMAL. An immature material from which cells and tissues develop.

BLASTOCYST. A cluster of cells representing multiple cell divisions that have occurred in the Fallopian tube after successful fertilization of an ovum by a sperm. This is the developmental form which must leave the Fallopian tube, enter the uterus, and implant itself in the uterus to achieve actual pregnancy.

BLEACHING. Technique used to brighten stained teeth.

BLEEDING DISORDER. Problems in the clotting mechanism of the blood.

BLENDED FAMILY. A family formed by the remarriage of a divorced or widowed parent. It includes the new husband and wife, plus some or all of their children from previous marriages.

BLEPHARITITS. An inflammation of the eyelid.

BLEPHAROPLASTY. Surgical reshaping of the eyelid.

BLOOD BANK. A laboratory that specializes in blood typing, antibody identification, and transfusion services.

BLOOD CLOT. A dense mat formed by certain components of the blood stream to prevent blood loss.

BLOOD CULTURE. A procedure where blood is collected from a vein and is placed in a small bottle that contains a special liquid; the liquid will make any organisms that are present in the blood sample grow. These organisms can then be grown and identified in the laboratory so that the proper antibiotic can be given to the patient.

BLOOD GAS ANALYSIS. A blood test that measures the level of oxygen, carbon dioxide, and pH in arterial blood. A blood gas analysis can help a physician assess how well the lungs are functioning.

BLOOD GLUCOSE. The main sugar that the body makes from the food in the diet.

BLOOD PERFUSION. A physiological term that refers to the process of nutritive delivery of arterial blood to a capillary bed in the biological tissue.

BLOOD SUGAR. The concentration of glucose in the blood.

BLOOD TYPE. Blood categories based on the presence or absence of certain antigens on the red blood cells.

BLOOD UREA NITROGEN (BUN). A waste product that is formed in the liver and collects in the bloodstream; patients with kidney failure have high BUN levels.

BLOOD VESSELS. General term for arteries, veins, and capillaries that transport blood throughout the body.

BLOOD-BRAIN BARRIER. A specialized, semi-permeable layer of cells around the blood vessels in the brain that controls which substances can leave the circulatory system and enter the brain.

BLOWOUT FRACTURE. A fracture or break in the orbit that is caused by sudden and violent impact to the area.

BODY DYSMORPHIC DISORDER. A psychiatric disorder marked by preoccupation with an imagined physical defect.

BODY IMAGE. A term that refers to a person's inner picture of his or her outward appearance. It has two components: perceptions of the appearance of one's body, and emotional responses to those perceptions.

BODY MASS INDEX (BMI). A measure of body fat: the ratio of body weight in kilograms to the square of body height in meters.

BODY PLETHYSMOGRAPHY. A very sensitive test given to measure damage to the lungs that might be missed by routine pulmonary function tests. The patient sits within a so-called airtight body box while various devices measure both the air pressure in the patient's alveoli and the airflow through the respiratory system.

BODYWORK. A term that covers a variety of therapies that include massage, realignment of the body, and similar techniques to treat deeply ingrained stresses and traumas carried in the tissues of the body.

BOIL. A collection of pus localized deep in the skin.

BONDING. Rebuilding, reshaping, and covering tooth defects using tooth-colored materials.

BONE DENSITOMETRY TEST. A test that quickly and accurately measures the density of bone.

BONE MARROW. A spongy tissue located in the hollow centers of certain bones, such as the skull and hip bones. Bone marrow is the site of blood cell generation.

BONE MARROW ASPIRATION AND BIOPSY. A procedure in which a needle is inserted into the large bones of the hip or spine and a small piece of marrow is removed for microscopic examination.

BONE MARROW BIOPSY. A procedure in which cellular material is removed from the pelvis or breastbone and examined under a microscope to look for the presence of abnormal blood cells characteristic of specific forms of leukemia and lymphoma.

BONE MARROW SUPPRESSION. A decrease in cells responsible for providing immunity, carrying oxygen, and those responsible for normal blood clotting.

BONE MARROW TRANSPLANT. A procedure in which a quantity of bone marrow is extracted through a needle from a donor, and then passed into a patient to replace the patient's diseased or absent bone marrow.

BONE SCAN. An x-ray study in which patients are given an intravenous injection of a small amount of a radioactive material that travels in the blood. When it reaches the bones, it can be detected by x ray to make a picture of their internal structure.

BONE SPUR. Also called an osteophyte, it is an outgrowth or ridge that forms on a bone.

BORDATELLA PERTUSSIS. A bacteria that causes whooping cough by attaching itself to cells in the respiratory tract.

BORDERLINE PERSONALITY DISORDER (BPD). A pattern of behavior characterized by impulsive acts, intense but chaotic relationships with others, identity problems, and emotional instability.

BOTULINUM TOXIN (BOTULIN). A neurotoxin made by *Clostridium botulinum*; causes paralysis in high doses, but is used medically in small, localized doses to treat disorders associated with involuntary muscle contraction and spasms, in addition to strabismus.

BOUGIE. A mercury-filled dilator in the shape of a cylinder or tapered cylinder. Bougies come in a range of different sizes.

BOUGIENAGE. The procedure of dilating tubal organs, like the esophagus, with a bougie or bougies.

BOVINE SPONGIFORM ENCEPHALOPATHY. A progressive, fatal disease of the nervous system of domestic animals. It is transmitted by eating infected food. Also known as Mad Cow disease.

BOWEL. The part of the intestines that is connected to the anus.

BOWEL LUMEN. The space within the intestine.

BOWEL OBSTRUCTION. Anything that prevents waste from moving normally to the anal opening.

BOWMAN'S CAPSULE. The structure surrounding the glomerulus.

BPH. Benign prostatic hyperplasia, a noncancerous disorder that causes the prostate to enlarge.

BRACES. An orthodontic appliance consisting or brackets cemented to the surface of each tooth and wires of stainless steel or nickel titanium alloy. Braces are used to treat malocclusion by changing the position of the teeth.

BRACHYTHERAPY. A type of radiation treatment for cancer in which the source of the radiation is applied directly to the surface of the body.

BRADYKINESIA. Extremely slow movement.

BRAIN DEATH. Irreversible cessation of brain function. Patients with brain death have no potential capacity for survival or for recovery of any brain function.

BRAIN STEM. The lower part of the brain directly connected to the spinal cord. It controls breathing and other vital functions.

BRAXTON HICKS' CONTRACTIONS. Short, fairly painless uterine contractions during pregnancy that may be mistaken for labor pains. They allow the uterus to grow and help circulate blood through the uterine blood vessels.

BRCA1 OR BRCA2 GENETIC MUTATION. A genetic mutation that predisposes otherwise healthy women to breast cancer.

BREAST BIOPSY. A procedure where suspicious tissue is removed and examined by a pathologist for cancer or other disease. The breast tissue may be obtained by open surgery, or through a needle.

BREECH BIRTH. Birth of a baby bottom-first, instead of the usual head first delivery. This can add to labor and delivery problems because the baby's bottom doesn't mold a passage through the birth canal as well as does the head.

BREECH POSITION. When a child is oriented feet first in the mother's uterus just before delivery.

BRIDGE. An appliance of one or more artificial teeth anchored by crowns on the adjacent teeth.

BRIEF PSYCHOTIC DISORDER. An acute, short-term episode of psychosis lasting no longer than one month. This disorder may occur in response to a stressful event.

BRIQUET'S SYNDROME. Another name for somatization disorder.

BROCA'S APHASIA. A condition characterized by either partial or total loss of the ability to express oneself, either through speech or writing. Hearing comprehension is not affected. This condition may result from a stroke, head injury, brain tumor, or infection.

BRONCHIAL. Relating to the air passages to and from the lungs including the bronchi and the bronchioles.

BRONCHIAL LAVAGE. A procedure that involves repeatedly washing the inside of the bronchial tubes of the lung.

BRONCHIAL TUBES. The major airways to the lungs and their main branches.

BRONCHIECTASIS. A disorder of the bronchial tubes marked by abnormal stretching, enlargement, or destruction of the walls. Bronchiectasis is usually caused by recurrent inflammation of the airway and is a diagnostic criterion of ABPA.

BRONCHIOLE. A very small thin-walled air passage in the lungs that branches off from a bronchus.

BRONCHITIS. Inflammation of the air passages of the lungs.

BRONCHOALVEOLAR LAVAGE. A way of obtaining a sample of fluid from the airways by inserting a flexible tube through the windpipe. Used to diagnose the type of lung disease.

BRONCHODILATOR. A drug that relaxes bronchial muscles resulting in expansion of the bronchial air passages.

BRONCHOPLEURAL FISTULA. An abnormal connection between an air passage and the membrane that covers the lungs.

BRONCHOSCOPE. An illuminated instrument that is inserted into the airway to inspect and retrieve objects from the bronchial tubes.

BRONCHOSCOPY. A medical test that enables a physician to examine the breathing passages and lungs by inserting a hollow, lighted tube into the nostril (or mouth). Sometimes cells are collected by washing the lungs with a small amount of fluid.

BRONCHUS (PLURAL, BRONCHI). One of the two major divisions of the airway that lead into the right and left lungs.

BRUCH'S MEMBRANE. A membrane in the eye between the choroid membrane and the retina.

BRUIT. A roaring sound created by a partially blocked artery.

BRUTON'S AGAMMAGLOBULINEMIA TYROSINE KINASE (BTK). An enzyme vital for the maturation of B cells.

BRUXISM. Habitual clenching and grinding of the teeth because of stress. The behavior usually occurs during sleep.

BUBOES. Smooth, oval, reddened, and very painful swellings in the armpits, groin, or neck that occur as a result of infection with the plague.

BUCK'S FASCIA. The deep connective tissue of the penis.

BUERGER'S DISEASE. An episodic disease that causes inflammation and blockage of the veins and arteries of the limbs. It tends to be present almost exclusively on men under age 40 who smoke, and may require amputation of the hand or foot.

BUFFY COAT. The thin layer of concentrated white blood cells that forms when a tube of blood is spun in a centrifuge.

BULBAR MUSCLES. Muscles that control chewing, swallowing, and speaking.

BULIMIA NERVOSA. An eating disorder characterized by binging and purging (self-induced vomiting) behaviors.

BUPROPION. An antidepressant medication given to smokers for nicotine withdrawal symptoms. It is sold under the trade name Zyban.

BURNOUT. An emotional condition marked by tiredness, loss of interest, or frustration that interferes with job performance. Burnout is usually regarded as the result of prolonged stress.

BURSAE. A closed sac lined with a synovial membrane and filled with fluid, usually found in areas subject to friction, such as where a tendon passes over a bone.

BURSITIS. Inflammation of a bursa, a fluid-filled cavity or sac. In the body, bursae are located at places where friction might otherwise develop.

BUSPIRONE. An antianxiety medication that is also given for withdrawal symptoms. It is sold under the trade name BuSpar.

BUTTERFLY BANDAGE. A narrow strip of adhesive with wider flaring ends (shaped like butterfly wings) used to hold the edges of a wound together while it heals.

BUTTON BATTERIES. Tiny, round batteries containing mercuric chloride that power items such as watches, hearing aids, calculators, cameras, and penlights.

BYPASS SURGERY. A surgical procedure that grafts blood vessels onto arteries to reroute the blood flow around blockages in the arteries (arteriosclerosis).

C

CA 125 (CANCER ANTIGEN 125). A tumor marker associated with ovarian cancer.

CA 15-3 (CANCER ANTIGEN 15-3). A tumor marker associated with breast cancer.

CA 19-9 (CANCER ANTIGEN 19-9). A tumor marker associated with pancreatic cancer.

CA 27-29 (BREAST CARCINOMA-ASSOCIATED ANTIGEN). A tumor marker associated with breast cancer.

CACHEXIA. Severe malnutrition involving muscle wasting and organ damage.

CADAVER. The human body after death.

CADAVER KIDNEY. A kidney from a brain-dead organ donor used for purposes of kidney transplantation.

CADAVER ORGAN. A pancreas, kidney, or other organ from a brain-dead organ donor.

CADAVERIC DONOR. An organ donor who has recently died of causes not affecting the organ intended for transplant.

CADUCEUS. The ancient and universal symbol of medicine consisting of the winged staff of Mercury and two intertwining serpents.

CAFFEINISM. A group of symptoms caused by excess caffeine.

CAGE. A four–question assessment for the presence of alcoholism in both adults and children.

CALCANEOUS. The heel bone.

CALCIFICATION. Hardening or stiffening due to calcium accumulation.

CALCIFIED. Hardened by calcium deposits.

CALCITONIN. A naturally occurring hormone made by the thyroid gland that can be used as a drug to treat Paget's disease.

CALCIUM. A mineral that helps build bone.

CALCIUM CHANNEL BLOCKER. A drug that blocks the entry of calcium into the muscle cells of small blood vessels (arterioles) and keeps them from narrowing.

CALCULI (SINGULAR, CALCULUS). Mineral deposits that can form a blockage in the urinary system.

CALCULUS. A hardened yellow or brown mineral deposit from unremoved plaque; also called tartar.

CALICIVIRUS. A member of the *Caliciviridae* family of viruses that includes noroviruses.

CALLUS. Thickened skin due to chronic rubbing or irritation.

CALORIC TESTING. Flushing warm and cold water into the ear stimulates the labyrinth and causes vertigo and nystagmus if all the nerve pathways are intact.

CALORIE. A unit of heat measurement used in nutrition to measure the energy value of foods. A calorie is the amount of heat energy needed to raise the temperature of 1 kilogram of water 1°C.

CALORIE REDUCTION. A decrease in the number of calories that a person consumes.

CANALICULI. Also known as lacrimal ducts, these tube-like structures carry the tears from the eyes to the lacrimal sac.

CANCER. A disease caused by uncontrolled growth of the body's cells.

CANCER STAGING. A surgical procedure to remove a lymph node and examine the cells for cancer. It determines the extent of the cancer and how far it has spread.

CANCER VACCINES. A treatment that uses the patient's immune system to attack cancer cells.

CANDIDIASIS. A common fungal infection caused by yeast that thrives in moist, warm areas of the body.

CANINE; CUSPID. Eyetooth; the conical, pointed tooth between the lateral incisor and the first primary molar or permanent premolar.

CANKER SORE. A blister-like sore on the inside of the mouth that can be painful but is not serious.

CANNABINOIDS. The chemical compounds that are the active principles in marijuana.

CANNULA. A tube inserted into a cavity to serve as a channel for the transport of fluid.

CAPILLARY. Smallest extremity of the arterial vessel, where oxygen and nutrients are released from the blood into the cells, and cellular waste is collected.

CAPILLARY BED. A dense network of tiny blood vessels that enables blood to fill a tissue or organ.

CAPSAICIN. An alkaloid found in hot peppers that is used in an inhalation test to identify patients with MCS.

CAPSID. The outer protein coat of a virus.

CAPSULAR CONTRACTURE. Thick scar tissue around a breast implant, which may tighten and cause discomfort and/or firmness.

CARBOHYDRATE. Sugars, starches, celluloses, and gums that are a major source of calories from foods.

CARBON DIOXIDE. A heavy, colorless gas that dissolves in water.

CARBON MONOXIDE. A colorless, odorless, highly poisonous gas.

CARBON MONOXIDE DIFFUSING TEST. Also called the transfer factor test, this test measures the ability of the patient's lungs to transfer blood gases.

CARBONIC ANHYDRASE INHIBITOR. A class of diuretic drugs that inhibit the enzyme carbonic anhydrase, an enzyme involved in producing bicarbonate, which is required for aqueous humor production by the ciliary tissues in the eye.

CARBOXYHEMOGLOBIN (COHB). Hemoglobin that is bound to carbon monoxide instead of oxygen.

CARBUNCLE. A large, deep skin abscess formed by a group or cluster of boils.

CARCINOGEN. An agent that is known to cause cancer.

CARCINOID SYNDROME. The pattern of symptoms (often including asthma and diarrhea) associated with carcinoid tumors of the digestive tract or lungs.

CARCINOMA IN SITU. Cancer that is confined to the cells in which it originated and has not spread to other tissues.

CARDIAC ANGIOGRAPHY. A procedure used to visualize blood vessels of the heart. A catheter is used to inject a dye into the vessels; the vessels can then be seen by x ray.

CARDIAC ARREST. A condition in which the heart stops functioning. Fibrillation can lead to cardiac arrest if not corrected quickly.

CARDIAC ARRHYTHMIA. An irregular heart rate (frequency of heartbeats) or rhythm (the pattern of heartbeats).

CARDIAC CATHETER. Long, thin, flexible tube that is threaded into the heart through a blood vessel.

CARDIAC CATHETERIZATION. A diagnostic procedure (using a catheter inserted through a vein and threaded through the circulatory system to the heart) which does a comprehensive examination of how the heart and its blood vessels function.

CARDIAC DYSRHYTHMIAS. Abnormal heart rate, rhythm, or sequence of rhythms.

CARDIAC MARKER. A substance in the blood that rises following a heart attack.

CARDIAC REHABILITATION. A structured program of education and activity offered by hospitals and other organizations.

CARDIAC SHUNT. A defect in the wall of the heart that allows blood from different chambers to mix.

CARDIAC TAMPONADE. Compression and restriction of the heart that occurs when the pericardium fills with blood or fluid. This increase in pressure outside the heart interferes with heart function and can result in shock and/or death.

CARDIOGENIC. Originating with the heart.

CARDIOLOGIST. A doctor who specializes in diagnosing and treating disorders of the heart.

CARDIOMEGALY. An enlarged heart.

CARDIOMYOPATHY. A disease of the heart muscle.

CARDIOPULMONARY. Relating to the heart and lungs.

CARDIOPULMONARY BYPASS MACHINE. A mechanical instrument that takes over the circulation of the body while heart surgery is taking place.

CARDIOPULMONARY DISEASE. Illness of the heart and lungs.

CARDIOPULMONARY RESUSCITATION (CPR). Using rescue breathing and chest compressions to help a person whose breathing and heartbeat have stopped.

CARDIOVASCULAR. Relating to the heart and blood vessels.

CARDIOVASCULAR DISEASE. A structural or functional abnormality of the heart, or of the blood vessels supplying the heart, that impairs its normal function.

CARDIOVERSION. A electrical shock delivered to the heart to restore a normal rhythm.

CARDIOVERTER. A device to apply electric shock to the chest to convert an abnormal heartbeat into a normal heartbeat.

CARIES. The medical term for tooth decay.

CARNASSIALS. The last upper premolar teeth in the mouths of cats and other carnivores, adapted to shear or puncture food. Carnassial teeth often cause puncture wounds when a cat bites a human.

CAROTENOIDS. Carotenoids are yellow to deep-red pigments.

CAROTID ARTERY. An artery located in the neck. There are two on each side of the neck. The internal carotid artery carries blood to the brain while the external carotid artery carries blood to skin and muscles of the face.

CAROTID ARTERY DISEASE. A condition in which the arteries in the neck that supply blood to the brain become clogged, causing the danger of a stroke.

CAROTID ENDARTERECTOMY. A surgical technique for removing intra-arterial obstructions of the internal carotid artery.

CARPAL TUNNEL. A passageway in the wrist, created by the bones and ligaments of the wrist, through which the median nerve passes.

CARPAL TUNNEL SYNDROME. A condition caused by compression of the median nerve in the carpal tunnel of the hand, characterized by pain.

CARRIER. A person who bears or carries a disease agent in or on their body and can transmit the disease to others, but is immune to the disease or has no symptoms of it.

CARRIER OIL. An oil used to dilute essential oils for use in massage and other skin care applications.

CARRIER STATE. The continued presence of an organism (bacteria, virus, or parasite) in the body that does not cause symptoms, but is able to be transmitted and infect other persons.

CARTILAGE. A flexible, fibrous type of connective tissue which serves as a base on which bone is built.

CASE MANAGER. A health-care professional who can provide assistance with a patient's needs beyond the hospital.

CASEIN HYDROLYSATE. A preparation made from the milk protein casein, which is hydrolyzed to break it down into its constituent amino acids. Amino acids are the building blocks of proteins.

CASTS. Small fibrous objects formed from materials that collect in the kidney tubules and are washed out by normal urine flow.

CATABOLIC. A metabolic process in which energy is released through the breakdown of complex molecules into simpler ones.

CATABOLISM. A process of metabolism that breaks down complex substances into simple ones.

CATALYST. A substance that changes the rate of a chemical reaction, but is not physically changed by the process.

CATAPLEXY. Sudden loss of muscle tone (often causing a person to fall), usually triggered by intense emotion. It is regarded as a diagnostic sign of narcolepsy.

CATARACT. A condition in which the lens of the eye turns cloudy and interferes with vision.

CATATONIA. Psychomotor disturbance characterized by muscular rigidity, excitement or stupor.

CATATONIC BEHAVIOR. Behavior characterized by muscular tightness or rigidity and lack of response to the environment. In some patients rigidity alternates with excited or hyperactive behavior.

CATECHOLAMINES. Family of neurotransmitters containing dopamine, norepinephrine and epinephrine, produced and secreted by cells of the adrenal medulla and the brain.

CATHARSIS. Therapeutic discharge of emotional tension by recalling past events.

CATHARTIC COLON. A poorly functioning colon, resulting from the chronic abuse of stimulant cathartics.

CATHETER. A hollow flexible tube that is inserted into a body cavity, duct, or vessel for the passage of fluids.

CATHETERIZATION. Inserting a tube into the bladder so that a patient can urinate without leaving the bed.

CATHODE. The negative electrode from which an electromagnetic current flows.

CATION. An ion carrying a positive charge due to a loss of electrons. Cations in the body include sodium, potassium, magnesium, and calcium ions.

CAT-SCRATCH DISEASE. An infectious disease caused by bacteria transmitted by the common cat flea that causes a self-limiting, mild infection in healthy people.

CAUDA EQUINA. The collection of spinal nerve roots that lie inside the spinal column below the end of the spinal cord. The name comes from the Latin for "horse's tail."

CAUDA EQUINA SYNDROME (CES). A group of symptoms characterized by numbness or pain in the legs and/or loss of bladder and bowel control, caused by compression and paralysis of the nerve roots in the cauda equina. CES is a medical emergency.

CAUSALGIA. A severe burning sensation sometimes accompanied by redness and inflammation of the skin. Causalgia is caused by injury to a nerve outside the spinal cord.

CAUTERIZE. To damage with heat or cold so that tissues shrink. It is an effective way to stop bleeding.

CAUTERY. The use of heat, electricity, or chemicals to destroy tissue.

CAVITY. A hole or weak spot in the tooth surface caused by decay.

CD4. A type of protein molecule in human blood that is present on the surface of 65% of human T cells. CD4 is a receptor for the HIV virus.

CD4 COUNT. A measure of the strength of the immune system.

CEA (CARCINOEMBRYONIC ANTIGEN). A tumor marker associated with many cancers, especially liver, intestinal, and pancreatic.

CECUM. The beginning of the large intestine and the place where the appendix attaches to the intestinal tract.

CELIAC DISEASE. A disease, occurring in both children and adults, which is caused by a sensitivity to

gluten, a protein found in grains. It results in chronic inflammation and shrinkage of the lining of the small intestine.

CELL. The smallest living units of the body which group together to form tissues and help the body perform specific functions.

CELLULITE. Dimpled skin that is caused by uneven fat deposits beneath the surface.

CELLULITIS. Inflammation of tissue due to infection.

CENTRAL LINE. A tube placed by needle into a large, central vein of the body.

CENTRAL NERVOUS SYSTEM (CNS). Part of the nervous system consisting of the brain, cranial nerves and spinal cord.

CENTRAL NERVOUS SYSTEM (CNS) DEPRESSANT. Any drug that tends to reduce the activity of the central nervous system. The major drug categories included in this classification are: alcohol, anesthetics, anti-anxiety medications, antihistamines, antipsychotics, hypnotics, narcotics, sedatives, and tranquilizers.

CENTRAL PRECOCIOUS PUBERTY (CPP). Precocious puberty resulting from the early maturation of the HPG axis.

CENTRAL RETINAL ARTERY. A branch of the ophthalmic artery that supplies blood to the retina and branches to form the arterioles of the retina.

CENTRAL RETINAL VEIN. Central blood vessel and its branches that drains the retina.

CENTROMERE. The centromere is the constricted region of a chromosome. It performs certain functions during cell division.

CEPHALOPELVIC DISPROPORTION (CPD). The condition in which the baby's head is too large to fit through the mother's pelvis.

CERCARIA (PLURAL, CERCARIAE). An intermediate-stage of the fluke larva, released into water by infected snails.

CEREBELLAR. Involving the part of the brain (cerebellum), which controls walking, balance, and coordination.

CEREBRAL. Pertaining to the brain.

CEREBRAL ANEURYSM. The dilation, bulging, or ballooning out of part of the wall of a vein or artery in the brain.

CEREBRAL ANGIOGRAPHY. A medical test in which an x-ray visible dye is injected into blood vessels to allow them to be imaged on an x ray.

CEREBRAL CORTEX. Brain region responsible for reasoning, mood, and perception.

CEREBRAL EDEMA. Movement of water into brain cells causing the cells to swell, which disrupts normal functioning of the cells.

CEREBRAL EMBOLISM. A blockage of blood flow through a vessel in the brain by a blood clot that formed elsewhere in the body and traveled to the brain.

CEREBRAL PALSY. Brain damage before, during, or just after birth that results in lack of muscle coordination and problems with speech.

CEREBRAL THROMBOSIS. A blockage of blood flow through a vessel in the brain by a blood clot that formed in the brain itself.

CEREBROSIDES. Fatty carbohydrates that occur in the brain and nervous system.

CEREBROSPINAL FLUID (CSF). The clear fluid that surrounds the spinal cord and brain and acts as a shock absorber.

CEREBROSPINAL FLUID ANALYSIS. An analysis that is important in diagnosing diseases of the central nervous system. The fluid within the spine will indicate the presence of viruses, bacteria, and blood. Infections such as encephalitis will be indicated by an increase of cell count and total protein in the fluid.

CEREBROVASCULAR DISEASE. Disorders affecting the blood vessels that supply the brain that may result in a stroke.

CERULOPLASMIN. A protein circulating in the bloodstream that binds with copper and transports it.

CERUMEN. The medical term for earwax.

CERVICAL. Relating to the top part of the spine that is composed of the seven vertebrae of the neck and the disks that separate them.

CERVICAL CANCER. Cancer of the entrance to the womb (uterus). The cervix is the lower, narrow part of the uterus (womb).

CERVICAL CANCER SCREENING. Use of the Papanicolaou (Pap) smear test to detect cervical cancer in the early curable stage.

CERVICAL CERCLAGE. A procedure in which the cervix is sewn closed; used in cases when the cervix

starts to dilate too early in a pregnancy to allow the birth of a healthy baby.

CERVICAL DYSPLASIA. Dysplasia is the abnormal growth of the epithelial cells. This is what a Pap smear will detect in the cervix.

CERVICAL INTRA-EPITHELIAL NEOPLASIA (CIN). A precancerous condition in which a group of cells grow abnormally on the cervix but do not extend into the deeper layers of this tissue.

CERVICAL POLYPS. Growths originating from the surface of the cervix or endocervical canal. These small, fragile growths hang from a stalk and protrude through the cervical opening (the os).

CERVICITIS. Cervicitis is an inflammation of the cervix or neck of the uterus.

CERVIX. A small cylindrical organ about an inch or so long and less than an inch around that makes up the lower part and neck of the uterus. The cervix separates the body and cavity of the uterus from the vagina.

CESAREAN SECTION; C-SECTION. A surgical procedure in which an incision is made in a woman's abdomen to deliver the infant from the uterus.

CESTODIASIS. Parasitic infection caused by the presence of adult tapeworms of the class Cestoda within the intestinal tract. Infection is caused by accidental consumption of tapeworm larvae.

CFTR. Cystic fibrosis transmembrane conductance regulator. The protein responsible for regulating chloride movement across cells in some tissues. When a person has two defective copies of the CFTR gene, cystic fibrosis is the result.

CGG OR CGG SEQUENCE. Shorthand for the DNA sequence: cytosine-guanine-guanine. Cytosine and guanine are two of the four molecules, otherwise called nucleic acids, that make up DNA.

CHAGAS DISEASE. A parasitic disease that causes mild early swelling at the site of the infection, then becomes asymptomatic for many years, but later may cause serious heart and digestive system problems. Parasites causing this disease are most common in rural Central and South America.

CHAKRA. One of seven major energy centers in the body, as defined by Hindu and yoga philosophy.

CHANCRE. An open sore with a firm or hard base that is the initial skin ulcer of primary syphilis.

CHARACTER DISORDER. Another name for personality disorder.

CHELATE. A chemical that binds to heavy metals in the blood, thereby helping the body to excrete them in urine.

CHELATION. The process by which a molecule encircles and binds to a metal and removes it from tissue.

CHELATION THERAPY. A method of removing copper or other heavy metals from the body by giving medications that bind to the metal and allow it to be excreted.

CHELATORS. Various compounds that bind to metals such as mercury.

CHEMOPREVENTIVE. Description of a drug given in order to prevent the development of a specific disease.

CHEMOTHERAPY. A cancer treatment that uses synthetic drugs to destroy the tumor either by inhibiting the growth of the cancerous cells or by killing the cancer cells.

CHEST X RAY. A diagnostic procedure in which a very small amount of radiation is used to produce an image of the structures of the chest (heart, lungs, and bones) on film.

CHI. Basic life energy.

CHIARI II ANOMALY. A structural abnormality of the lower portion of the brain (cerebellum and brain stem) associated with spina bifida. The lower structures of the brain are crowded and may be forced into the foramen magnum, the opening through which the brain and spinal cord are connected.

CHILD DEVELOPMENT. The process of physical, intellectual, emotional, and social growth that occurs from infancy through adolescence.

CHILDREN'S HOSPICE. A holistic philosophy that addresses the physical, emotional, social, and spiritual needs of children with life-threatening illnesses, as well as the needs of their families.

CHIROPRACTIC. A method of treatment based on the interactions of the spine and the nervous system. Chiropractors adjust or manipulate segments of the patient's spinal column in order to relieve pain.

CHLAMYDIA. One of the most common sexually transmitted diseases in the United States. It can cause discharge, inflammation and burning during urination. About half of the cases of nongonococcal urethritis are due to chlamydia.

CHLAMYDIA PSITTACI. An organism related to bacteria that infects some types of birds and can be transmitted to humans to cause parrot fever.

CHLOASMA. A skin discoloration common during pregnancy, also known as the "mask of pregnancy" or melasma, in which blotches of pale brown skin appear on the face. It is usually caused by hormonal changes.

CHLOROQUINE. An antimalarial drug that was first used in the 1940s, until the first evidence of quinine resistance appeared in the 1960s. It is now ineffective against falciparum malaria almost everywhere. However, because it is inexpensive, it is still the antimalarial drug most widely used in Africa. Native individuals with partial immunity may have better results with chloroquine than a traveler with no previous exposure.

CHOLANGIOGRAPHY. Radiographic examination of the bile ducts after injection with a special dye.

CHOLANGITIS. Infection or inflammation of the bile ducts; often causes abdominal pain, fever, and jaundice.

CHOLECYSTECTOMY. Surgical removal of the gallbladder.

CHOLECYSTITIS. Infection and inflammation of the gallbladder, causing severe pain and rigidity in the upper right abdomen.

CHOLECYSTOTOMY. An operation during which the gallbladder is opened, gallstones are removed, and excess bile is drained. The gallbladder is not removed.

CHOLEDOCHOLITHIASIS. The presence of gallstones within the common bile duct.

CHOLELITHIASIS. Also known as gallstones, these hard masses are formed in the gallbladder or passages, and can cause severe upper right abdominal pain radiating to the right shoulder, as a result of blocked bile flow.

CHOLELITHOTOMY. Surgical incision into the gallbladder to remove stones.

CHOLERA. A severe bacterial infection of the small intestine characterized by profuse diarrhea and eventual dehydration. Cholera is still a frequent cause of death among children in developing countries.

CHOLESCINTIGRAPHY. Another term for a gallbladder nuclear medicine scan.

CHOLESTATIS. Stoppage or suppression of the flow of bile.

CHOLESTEATOMA. A cystic mass of cells in the middle ear, occurring as a congential defect or as a serious complication of a disease or traumtic condition of the ear.

CHOLESTEROL. A fat–soluble steroid alcohol (sterol) found in animal fats and oils, and in egg yolks. The human body needs cholesterol to produce vitamin D.

CHOLESTYRAMINE (QUESTRAN). A drug used to bind with bile acids and prevent their reabsorption and to stimulate fat absorption.

CHOLINERGIC DRUG. A medication that mimics or enhances the action of the neurotransmitter acetylcholine.

CHOLINERGIC NERVES. Nerves that are stimulated by acetylcholine.

CHOLINESTERASE INHIBITORS. Drugs that may slow the progression of AD by inhibiting the enzymes that break down acetylcholine.

CHOREA. A term that is used to refer to rapid, jerky, involuntary movements of the limbs or face that characterize several different disorders of the nervous system, including chorea of pregnancy and Huntington's chorea as well as Sydenham's chorea.

CHORION. The outer embryonic membrane of the developing fetus that gives rise to the placenta. Inside the chorion is the amniotic sac or sacs, inside of which are the fetuses.

CHORIONIC VILLI. Microscopic, finger-like projections that emerge from the outer sac which surrounds the developing baby. Chorionic villi are of fetal origin and eventually form the placenta.

CHORIONIC VILLUS SAMPLING (CVS). A procedure used for prenatal diagnosis at 10–12 weeks gestation. Under ultrasound guidance a needle is inserted either through the mother's vagina or abdominal wall and a sample of cells is collected from around the early embryo. These cells are then tested for chromosome abnormalities or other genetic diseases.

CHOROID. The part of the uveal tract behind the ciliary body. The choroid underlies and nourishes the retina and absorbs scattered light.

CHROMATOGRAPHY. A family of laboratory techniques that separate mixtures of chemicals into their individual components.

CHROMOSOME. A microscopic thread–like structure found within each cell of the body consisting of a

complex of proteins and DNA. Humans have 46 chromosomes arranged into 23 pairs.

CHRONIC. A disease or condition that progresses slowly but persists or reoccurs over time.

CHRONIC BRONCHITIS. A smoking-related respiratory illness in which the membranes that line the bronchi, or the lung's air passages, narrow over time. Symptoms include a morning cough that brings up phlegm, breathlessness, and wheezing.

CHRONIC HEPATITIS. Long lasting inflammation of the liver due to viruses or other causes.

CHRONIC KIDNEY FAILURE. End-stage renal disease (ESRD); chronic kidney failure is diagnosed as ESRD when kidney function falls to 5–10% of capacity.

CHRONIC LYMPHOCYTIC LEUKEMIA. A cancer of the blood cells characterized by large numbers of cancerous, mature white blood cells and enlarged lymph nodes.

CHRONIC MYELOGENOUS LEUKEMIA (CML). Also called chronic myelocytic leukemia, a malignant disorder that involves abnormal accumulation of white cells in the marrow and bloodstream.

CHRONIC OBSTRUCTIVE LUNG DISEASE. A common form of lung disease in which breathing, and therefore gas exchange, is labored and increasingly difficult.

CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD). A term used to describe chronic lung diseases, like chronic bronchitis, emphysema, and asthma.

CHRONIC OTITIS MEDIA. Inflammation of the middle ear with signs of infection lasting three months or longer.

CHRONIC PAIN. Pain that lasts beyond the term of an injury or painful stimulus.

CHRONIC RENAL (KIDNEY) FAILURE. Progressive loss of kidney function over several years that can result in permanent kidney failure requiring dialysis.

CHYMOPAPAIN. An enzyme from the milky white fluid of the papaya, used for medical purposes in chemonucleolysis.

CILIA (SINGULAR, CILIUM). Tiny hair-like projections from a cell. Within the respiratory tract, the cilia act to move mucus along, in an effort to continually flush out and clean the respiratory tract.

CILIARY BODY. A structure in the eye that contains muscles that will affect the focusing of the lens.

CILIARY MUSCLES. The small muscles that permit the lens to change its shape in order to focus on near or distant objects.

CILIATED. Covered with short, hair-like protrusions, like *B. coli* and certain other protozoa. The cilia or hairs help the organism to move.

CIRCADIAN RHYTHM. Any body rhythm that recurs in 24-hour cycles. The sleep-wake cycle is an example of a circadian rhythm.

CIRCULATION. The passage of blood and delivery of oxygen through the veins and arteries of the body.

CIRCUMCISION. A procedure, usually with religious or cultural significance, in which the prepuce—the skin covering the tip of the male penis or the female clitoris, is cut away.

CIRRHOSIS. A chronic degenerative disease of the liver, in which normal cells are replaced by fibrous tissue. Cirrhosis is a major risk factor for the later development of liver cancer.

CITALOPRAM HYDROBROMIDE. An SSRI that is highly specific for serotonin reuptake.

CLASSIC INCISION. In a cesarean section, an incision made vertically along the uterus.

CLASSIC KAPOSI'S SARCOMA. A form of KS that usually affects older men of Mediterranean or eastern European backgrounds and produces tumors on the lower legs.

CLASSICAL CONDITIONING. The memory system that links perceptual information to the proper motor response. For example, Ivan Pavlov conditioned a dog to salivate when a bell was rung.

CLAUDICATION. Cramping or pain in a leg caused by poor blood circulation. This condition is frequently caused by hardening of the arteries (atherosclerosis). Intermittent claudication occurs only at certain times, usually after exercise, and is relieved by rest.

CLEAN CATCH SPECIMEN. A urine specimen that is collected from the middle of the urine stream after the first part of the flow has been voided.

CLEFT PALATE. Congenital defect marked by a split in the roof of the mouth.

CLINDAMYCIN. An antibiotic that can be used instead of penicillin.

CLINICAL AROMATHERAPY. Aromatherapy is the therapeutic use of plant-derived, aromatic essential oils to promote physical and psychological well-being. It is sometimes used in combination with

massage and other therapeutic techniques as part of a holistic treatment approach.

CLINICAL NUTRITION. The use of diet and nutritional supplements as a way to enhance health prevent disease.

CLINICAL TRIALS. Highly regulated and carefully controlled patient studies, where either new drugs to treat cancer or novel methods of treatment are investigated.

CLITORIDECTOMY. A procedure in which the clitoris and possibly some of the surrounding labial tissue at the opening of the vagina is removed.

CLITORIS. The small erectile organ at the front of the female vulva that is the site of female sexual pleasure.

CLOFIBRATE (ALTROMED-S). Medication used to lower levels of blood cholesterol and triglycerides.

CLONIC. Referring to clonus, rapid contractions and relaxations of a muscle.

CLOSED-HEAD INJURY. An injury to the head in which the skull is not broken or penetrated.

CLOSTRIDIUM. A genus of deadly bacteria that are responsible for tetanus and other serious diseases, including botulism and gangrene from war wounds. Clostridia thrives without oxygen.

CLOT. A soft, semi-solid mass that forms when blood gels.

CLOTTING FACTOR. Also known as coagulation factors. Proteins in the plasma that serve to activate various parts of the blood clotting process by being transformed from inactive to active form.

CLUBBING. Rounding of the ends and swelling of fingers found in people with lung disease.

CNS DEPRESSANT. Anything that depresses, or slows, the sympathetic impulses of the central nervous system (i.e., respiratory rate, heart rate).

COAGULATING FACTORS. Components within the blood that help form clots.

COAGULATION. The entire process of blood clotting.

COAGULATION CASCADE. The sequence of biochemical activities, involving clotting factors, that stop bleeding by forming a clot.

COAGULATION FACTORS. Specific coagulation proteins in the blood required for clotting. Coagulation proteins are designated with roman numerals I through XIII.

COAGULOPATHY. A disorder in which blood is either too slow or too quick to coagulate (clot).

COARCTATION. The medical term for a constriction or narrowing.

COARCTATION OF THE AORTA. A congenital defect in which severe narrowing or constriction of the aorta obstructs the flow of blood.

COBB ANGLE. A measure of the curvature of scoliosis, determined by measurements made on x rays.

COCCYDYNIA. Also called coccygodynia. Pain in or around the coccyx.

COCCYX. The last bone of the spinal column, consisting of three to five fused vertebrae that connect with the sacrum, a part of the pelvis.

COCHLEA. The hearing part of the inner ear. This snail-shaped structure contains fluid and thousands of microscopic hair cells tuned to various frequencies, in addition to the organ of Corti (the receptor for hearing).

COENZYME. A substance needed by enzymes to produce many of the reactions in energy and protein metabolism in the body.

COENZYME Q_{10}. A substance used by cells in the human body to produce energy for cell maintenance and growth. It is being studied as a possible preventive for migraine headaches.

COGNITION. The mental activities associated with thinking, learning, and memory.

COGNITIVE BEHAVIORAL THERAPY. A psychotherapeutic approach that aims at altering cognitions—including thoughts, beliefs, and images—as a way of altering behavior.

COGNITIVE PROCESSES. Thought processes (i.e., reasoning, perception, judgment, memory).

COGNITIVE RESTRUCTURING. The process of replacing maladaptive thought patterns with constructive thoughts and beliefs.

COGNITIVE-BEHAVIORAL THERAPY (CBT). A psychotherapeutic approach that emphasizes correcting distorted thinking patterns and changing one's behaviors accordingly.

COINFECTION. Invasion of the body by two viruses at about the same time.

COITUS. Sexual intercourse.

COLCHICINE. A compound that blocks the assembly of microtubules–protein fibers necessary for cell

division and some kinds of cell movements, including neutrophil migration. Side effects may include diarrhea, abdominal bloating, and gas.

COLD AGGLUTININS. Antibodies that cause clumping of red blood cells when the blood temperature falls below normal body temperature (98.6°F/37°C).

COLD SORE. A small blister on the lips or face, caused by a virus. Also called a fever blister.

COLECTOMY. Surgical removal of the large bowel.

COLITIS. An inflammation of the large intestine that occurs in some cases of balantidiasis. It is marked by cramping pain and the passing of bloody mucus.

COLLAGEN. A protein that provides structural support; the main component of connective tissue.

COLLAGEN-VASCULAR DISEASE. Various diseases inflaming and destroying connective tissue.

COLLATERAL VESSEL. A side branch or network of side branches of a large blood vessel.

COLLATERALS. Alternate pathways for arterial blood.

COLON. The major part of the large intestine; a digestive system organ.

COLONIZATION. The presence of bacteria on a body surface (like on the skin, mouth, intestines or airway) without causing disease in the person.

COLONOSCOPE. A thin, flexible, hollow, lighted tube that is inserted through the anus and rectum to the colon to enable the physician to view the entire lining of the colon.

COLONOSCOPY. A diagnostic endoscopic procedure that uses a long flexible tube called a colonoscope to examine the inner lining of the entire colon; may be used for colorectal cancer screening or for a more thorough examination of the colon.

COLONY COUNT. A measurement of the growth of bacteria in a urine sample that has been cultured for 24 to 48 hours.

COLORECTAL CANCER. Cancer of the large intestine, or colon, including the rectum.

COLOSTOMY. A surgical procedure in which an opening is made in the wall of the abdomen to allow a part of the large intestine (the colon) to empty outside the body.

COLPOSCOPE. An instrument used for examination of the vagina and cervix. Part of the instrument includes a magnifying lens for better visualization.

COLPOSCOPY. Diagnostic procedure using a hollow, lighted tube (colposcope) to look inside the cervix and uterus.

COLUMELLA. The strip of skin running from the tip of the nose to the upper lip, which separates the nostrils.

COMA. A state of prolonged unconsciousness in which a person cannot respond to spoken commands or mildly painful physical stimuli.

COMEDO, COMEDONE. A hard plug composed of sebum and dead skin cells.

COMEDOLYTIC. A drug that breaks up comedones and opens clogged pores.

COMMINUTED FRACTURE. A fracture where there are several breaks in a bone creating numerous fragments.

COMMON BILE DUCT. The branching passage through which bile—a necessary digestive enzyme—travels from the liver and gallbladder into the small intestine. Digestive enzymes from the pancreas also enter the intestines through the common bile duct.

COMMON COLD. A mild illness caused by a upper respiratory viruses. Usual symptoms include nasal congestion, coughing, sneezing, throat irritation, and a low-grade fever.

COMMON PATHWAY. The pathway that results from the merging of the extrinsic and intrinsic pathways. The common pathway includes the final steps before a clot is formed.

COMMUNITY-ACQUIRED. Refers to an infectious disease that is passed among individuals who have close contact with one another.

COMORBID. Referring to the presence of one or more diseases or disorders in addition to the patient's primary disorder.

COMPARTMENT SYNDROME. Compartment syndrome is a condition in which a muscle swells but is constricted by the connective tissue around it, which cuts off blood supply to the muscle.

COMPATIBLE DONOR. A person whose tissue and blood type are the same as the recipient's.

COMPLEMENT. One of several proteins in the blood that acts with other proteins to assist in killing bacteria.

COMPLEMENTARY THERAPY. A therapy is called complementary when it is used in addition to conventional cancer treatments.

COMPLETE BLOOD COUNT (CBC). A blood test to check the numbers of red blood cells, white blood cells, and platelets in the blood.

COMPLETE DENTURE. A full set of upper or lower teeth, mounted in a plastic base. Dentures are also called false teeth.

COMPLEX CARBOHYDRATES. Complex carbohydrates are broken down by the body into simple sugars for energy, are found in grains, fruits and vegetables. They are generally recommended in the diet over refined sugar and honey, because they are a more steady source of energy and often contain fiber and nutrients as well.

COMPLIANCE. A term used to describe how well a patient's behavior follows medical advice.

COMPLICATED GRIEF. An abnormal response to bereavement that includes unrelieved yearning for the dead person, the complete loss of previous positive beliefs or worldviews, and a general inability to function.

COMPOSITE FILLING. A resin material that is tooth colored and is used to fill a tooth once decay has been removed. It is used most often in front teeth, but may be used in any tooth for aesthetic reasons.

COMPOUND FRACTURE. A fracture in which the broken end or ends of the bone have torn through the skin. Compound fractures are also known as open fractures.

COMPOUND HETEROZYGOTES. Individuals who have one gene in a pair with one mutation and the other gene in the pair has a different mutation.

COMPRESSED AIR. Air that is held under pressure in a tank to be breathed by underwater divers. A tank of compressed air is part of a diver's scuba (self-contained underwater breathing apparatus) gear.

COMPRESSION. An increase in pressure from the surrounding water that occurs with increasing diving depth.

COMPULSION. A repetitive or ritualistic behavior that a person performs to reduce anxiety. Compulsions often develop as a way of controlling or undoing obsessive thoughts.

COMPULSIVE GAMBLING DISORDER. An impulse control disorder in which an individual cannot resist gambling despite repeated losses.

COMPUTED TOMOGRAPHY (CT OR CAT) SCAN. An imaging technique in which cross-sectional x rays of the body are compiled to create a three-dimensional image of the body's internal structures.

COMT INHIBITORS. Drugs that block catechol-o-methyl transferase, an enzyme that breaks down dopamine. COMT inhibitors include entacapone and tolcapone.

CONCENTRATION. Refers to the amount of solute present in a solution, compared to the total amount of solvent.

CONCEPTION. The union of egg and sperm to form a fetus.

CONDITIONING. Process of preparing a patient to receive marrow donation, often through the use of chemotherapy and radiation therapy.

CONDOM. A thin sheath worn over the penis during sexual intercourse to prevent pregnancy or the transmission of STDs. There are also female condoms.

CONDUCT DISORDER. A behavioral and emotional disorder of childhood and adolescence. Children with a conduct disorder act inappropriately, infringe on the rights of others, and violate societal norms.

CONDUCTION APHASIA. A condition characterized by the inability to repeat words, sentences, or phrases as a result of a stroke, head injury, brain tumor, or infection.

CONDUCTIVE HEARING LOSS. A type of medically treatable hearing loss in which the inner ear is usually normal, but there are specific problems in the middle or outer ears that prevent sound from getting to the inner ear in a normal way.

CONDYLOMATA ACUMINATA (SINGULAR, CONDYLOMA ACUMINATUM). The medical term for infectious warts on the genitals caused by HPV.

CONDYLOMATA LATA. Highly infectious patches of wart-like pink or gray skin legions in moist areas of the body that occur during secondary syphilis.

CONES. Receptor cells that allow the perception of colors.

CONFABULATION. An attempt to fill in memory gaps by fabricating information or details.

CONFIRMATORY TYPING. Repeat tissue typing to confirm the compatibility of the donor and patient before transplant.

CONGENITAL. A condition present at birth.

CONGENITAL CYSTIC ADENOMATOID MALFORMATION (CCAM). A condition in which one or more lobes of the fetal lungs develop into fluid-filled sacs called cysts.

CONGENITAL DIAPHRAGMATIC HERNIA (CDH). A condition in which the fetal diaphragm—the muscle dividing the chest and abdominal cavity—does not close completely.

CONGENITAL HEART DEFECTS. Abnormal formation of structures of the heart or of its major blood vessels present at birth.

CONGESTIVE CARDIOMYOPATHY. Also called dilated cardiomyopathy; cardiomyopathy in which the walls of the heart chambers stretch, enlarging the heart ventricles so they can hold a greater volume of blood than normal.

CONGESTIVE HEART FAILURE. A condition in which the heart cannot pump enough blood to supply the body's tissues with sufficient oxygen and nutrients; back up of blood in vessels and the lungs causes buildup of fluid (congestion) in the tissues.

CONIZATION. Cone biopsy; removal of a cone–shaped section of tissue from the cervix for diagnosis or treatment.

CONJUCTIVA. The mucous membrane that covers the white part of the eyes and lines the eyelids.

CONN'S SYNDROME. A disorder caused by excessive aldosterone secretion by a benign tumor of one of the adrenal glands. This results in malfunction of the body's salt and water balance and subsequently causes hypertension. Symptoms include thirst, muscle weakness, and excessive urination.

CONNECTIVE TISSUE. A group of tissues responsible for support throughout the body, including cartilage, bone, fat, tissue underlying skin, and tissues that support organs, blood vessels, and nerves throughout the body.

CONSANGUNITY. Related from a common ancestor; blood relative.

CONSOLIDATION. A condition in which lung tissue becomes firm and solid rather than elastic and air-filled because it has accumulated fluids and tissue debris.

CONSTIPATION. The delayed or infrequent passage of dry, hard feces.

CONTACT DERMATITIS. Irritant dermatitis; direct skin contact with a substance that causes inflammation in some people.

CONTAMINATION. The process by which an object or body part becomes exposed to an infectious agent such as a virus.

CONTINENCE. The ability to control one's bladder and bowel functions.

CONTINUITY. Uninterrupted and successive.

CONTINUOUS POSITIVE AIRWAY PRESSURE (CPAP). A ventilation device that blows a gentle stream of air into the nose during sleep to keep the airway open.

CONTRACEPTION. The use of a device, sexual practice, or chemical intended to prevent conception; birth control.

CONTRACTION. A tightening of the uterus during pregnancy. Contractions may or may not be painful and may or may not indicate labor.

CONTRACTURE. A tightening of muscles that prevents normal movement of the associated limb or other body part.

CONTRAST AGENT. A chemical or other substance placed in the body to show structures that would not otherwise be visible on x ray or other imaging studies.

CONTRAST HYDROTHERAPY. A series of hot and cold water applications. A hot compress (as hot as an individual can tolerate) is applied for three minutes followed by an ice cold compress for 30 seconds. These applications are repeated three times each and ending with the cold compress.

CONTRAST MEDIUM. A substance that is swallowed or injected into the body to create clearer images in radiographic studies of internal structures.

CONTRAST SOLUTION. A liquid dye injected into the body that allows veins to be seen by x rays. Without the dye, the veins could not be seen on x rays.

CONVENTIONAL THERAPY. Treatments that are widely accepted and practiced by the mainstream medical community.

CONVERSION DISORDER. A somatoform disorder characterized by the transformation of a psychological feeling or impulse into a physical symptom. Conversion disorder was previously called hysterical neurosis, conversion type.

CONVULSION. Involuntary contractions of body muscles that accompany a seizure episode.

COOLEY'S ANEMIA. Another name for the most severe form of beta-thalassemia. It is named for Thomas Benton Cooley (1871–1945), an American pediatrician who first described it in the children of Italian immigrants.

COPING. In psychology, a term that refers to a person's patterns of response to stress.

COPROLALIA. The involuntary expression of obscene words or phrases.

COPROPRAXIA. The involuntary display of unacceptable/obscene gestures.

COR PULMONALE. Enlargement and structural change of the right ventricle of the heart as a result of emphysema or other respiratory disorder.

CORDOCENTESIS. A procedure for delivering a blood transfusion to a fetus. It involves a fine needle being threaded through a pregnant woman's abdomen and into the umbilical cord with the aid of ultrasound imaging.

CORNEA. A transparent structure of the eye over the iris and pupil; light must pass through the cornea to make vision possible.

CORNEAL ABRASION. A scratch on the surface of the eyeball.

CORONARY. Of or relating to the heart.

CORONARY ARTERIES. The arteries that provide blood to the heart. The coronary arteries surround the heart like a crown, coming out of the aorta, arching down over the top of the heart, and dividing into two branches.

CORONARY ARTERY BYPASS. Surgical procedure to reroute blood around a blocked coronary artery.

CORONARY ARTERY DISEASE (CAD). Also called atherosclerosis, it is a build-up of fatty matter and debris in the coronary artery wall that causes narrowing of the artery.

CORONARY BLOOD VESSELS. The arteries and veins that supply blood to the heart muscle.

CORONARY BYPASS SURGERY. Surgery in which a section of blood vessel is used to bypass a blocked coronary artery and restore an adequate blood supply to the heart muscle.

CORONARY OCCLUSIVE ARTERY DISEASE. Blockage of the arteries that supply blood to the heart; frequently a precursor to a heart attack.

CORONAVIRUS. One of a family of RNA-containing viruses known to cause severe respiratory illnesses. In March 2003, a previously unknown coronavirus was identified as the causative agent of severe acute respiratory syndrome, or SARS.

CORPORA CAVERNOSA. The pair of columns of erectile tissue on either side of the penis that, together with the corpus spongiosum, produce an erection when filled with blood.

CORPUS CAVERNOSUM (PLURAL, CORPORA CAVERNOSA). One of two rods of spongy tissue in the penis that become engorged with blood in order to produce an erection.

CORPUS LUTEUM. A small, yellow structure that forms in the ovary after an egg has been released.

CORTEX. The thin convoluted surface of the brain comprised primarilyof cell bodies of neurons.

CORTICAL. Regarding the cortex, or the outer layer of the brain, as distinguished from the inner portion.

CORTICOSTEROID. A class of drugs based on hormones formed in the adrenal gland, used to reduce inflammation. They increase the likelihood of hyperinfection syndrome in patients with threadworm infection.

CORTISOL. A hormone produced by the adrenal cortex. It is partially responsible for regulating blood sugar levels.

CORTISONE. Glucocorticoid produced by the adrenal cortex in response to stress. Cortisone is a steroid and has anti-inflammatory and immunosuppressive properties.

COUGH SUPPRESSANT. Medicine that stops or prevents coughing.

COUGHING. Coughing helps break up secretions in the lungs so that the mucus can be suctioned out or expectorated. Patients sit upright and inhale deeply through the nose. They then exhale in short puffs or coughs. Coughing is repeated several times per day.

COUNTERTRANSFERENCE. The analyst s emotional reaction to or entanglement with the analysand.

COWPOX. A mild disease in cows that is caused by a poxvirus.

COX-2 INHIBITORS. A class of newer NSAIDs that are less likely to cause side effects in the digestive tract. COX-2 inhibitors work by inhibiting the production of cyclooxygenase-2, an enzyme involved in inflammation.

COXSACKIEVIRUS B. A type of virus in the group Enterovirus that causes an infection similar to polio, but without paralysis.

CRABS. An informal term for pubic lice.

CRANIAL NERVES. The set of twelve nerves found on each side of the head and neck that control the sensory and muscle functions of a number of organs such as the eyes, nose, tongue face and throat.

CRANIOCAUDAL. Head to tail, x-ray beam directly overhead the part being examined.

CRANIOPHARYNGIOMA. A tumor near the pituitary gland in the craniopharyngeal canal that often results in intracranial pressure.

CRANIOSYNOSTOSIS. A premature closure of one or more of the joints (fissures) between the bones of the skull, which causes an abnormally shaped skull.

CRANIOTOME. A type of surgical drill used to operate on the skull. It has a self-controlled system that stops the drill when the bone is penetrated.

CRANIOTOMY. Procedure to remove a lesion in the brain through an opening in the skull.

C-REACTIVE PROTEIN (CRP). A protein present in blood serum in various abnormal states, like inflammation.

CREATININE. The metabolized by-product of creatine, an organic acid that assists the body in producing muscle contractions. Creatinine is found in the bloodstream and in muscle tissue. It is removed from the blood by the kidneys and excreted in the urine.

CREEPING ERUPTION. Itchy irregular, wandering red lines on the foot made by burrowing larvae of the hookworm family and some roundworms.

CREPITUS. A crackling or crunching sound heard when the ends of a fractured piece of bone rub against each other.

CRETINISM. Severe hypothyroidism that is present at birth and characterized by severe mental retardation.

CREUTZFELD-JAKOB DISEASE. A rare, often fatal disease of the brain, characterized by gradual dementia and loss of muscle control that occurs most often in middle age and is caused by a slow virus.

CRIB DEATH. Another name for SIDS. It is often called cot death in the United Kingdom, Australia, and New Zealand.

CRIBRIFORM PLATE. The horizontal bone plate perforated with several holes for the passage of olfactory nerve filaments from the nasal cavity.

CRICOTHYROIDOTOMY. An emergency tracheotomy that consists of a cut through the cricothyroid membrane to open the patient's airway as fast as possible.

CRIGLER-NAJJAR SYNDROME. A moderate to severe form of hereditary jaundice.

CROHN'S DISEASE. A chronic inflammatory disease of unknown cause, involving any part of the gastrointestinal tract from mouth to anus, but commonly involving the large intestine, with scarring and thickening of the bowel wall. Crohn's disease frequently leads to intestinal obstruction and has a high rate of recurrence after treatment.

CROSSBITE. The condition in which the upper teeth bite inside the lower teeth.

CROSS-DRESSING. Dressing in clothing that is stereotypical of the opposite sex.

CROSSMATCH. A laboratory test done to confirm that blood from a donor and blood from the recipient are compatible.

CROSS-REACTION. A reaction that occurs in blood testing when a disease agent reacts to the specific antibody for another disease agent. Cross-reactions are common in blood tests for fluke infections because the different species are closely related.

CROSS-TOLERANT. A drug that has the same pharmacological effect as another is considered cross-tolerant. Cross-tolerant drugs are often used in treating withdrawal syndromes.

CROWN. The upper part of the tooth, covered by enamel; dental restoration that is a protective shell fitting over a tooth.

CRYOABLATION. A technique for removing cancerous tissue by killing it with extreme cold.

CRYOGEN. A substance with a very low boiling point, such as liquid nitrogen, used in cryotherapy treatment.

CRYOGLOBULIN. An abnormal blood protein associated with several diseases. It is characterized by its tendency to clump in cold temperatures.

CRYOGLOBULINEMIA. Condition in which protein in the blood forms particles in the cold, blocking blood vessels and leading to pain and numbness of the extremities.

CRYOSURGERY. Freezing and destroying abnormal cells.

CRYOTHERAPY. Cancer treatment in which the tumor is destroyed by exposure to intense cold.

CRYPTORCHIDISM. Undescended testes.

CRYPTOSPORIDIUM. A type of parasitic protozoa.

CT SCAN (COMPUTED TOMOGRAPHY SCAN). Cross-sectional x rays of the body are compiled to create a three-dimensional image of the body's internal structures.

CULTURE. A laboratory procedure in which a sample from a wound, the blood or other body fluid is taken from an infected person. The sample is placed in conditions under which bacteria can grow. If bacteria grow, identification tests are done to determine the bacteria species causing the infection.

CURETTAGE. The removal of tissue or growths by scraping with a curette.

CURETTE. A surgical instrument with a circular cutting loop at one end. The curette is pulled over the skin lesion in repeated strokes to remove one portion of the lesion at a time.

CUSHING'S SYNDROME. A group of conditions caused by increased production of cortisol hormones or by the administration of glucocorticoid hormones (cortisone-like hormones).

CUT. Separation of skin or other tissue made by a sharp edge, producing regular edges.

CUTANEOUS. Pertaining to the skin.

CYANOSIS. A bluish tinge to the skin that can occur when the blood oxygen level drops too low.

CYANOTIC. Marked by bluish discoloration of the skin due to a lack of oxygen in the blood. It is one of the types of congenital heart disease.

CYCLIC VOMITING SYNDROME (CVS). Episodes of severe nausea, gagging, and vomiting in children that last for hours or a day or two, repeat at regular intervals, and have no known cause.

CYCLICAL NEUTROPENIA. A rare genetic blood disorder in which the patient's neutrophil level drops below 500/mm^3 for six to eight days every three weeks.

CYCLOTHYMIA. A milder form of bipolar disorder characterized by alternating hypomania and less severe depressive episodes.

CYST. A protective sac that includes either fluid or the cell of an organism. The cyst enables many organisms to survive in the environment for long periods of time without need for food or water.

CYSTECTOMY. Surgical removal of a cyst.

CYSTIC FIBROSIS. A genetic disease that causes multiple digestive, excretion, and respiratory complications. Among the effects, the pancreas fails to provide secretions needed for the digestion of food.

CYSTICERCOSIS. Parasitic infection caused by the presence of immature tapeworm larvae (cysticerci) that have developed outside the intestinal tract. Infection is caused by accidental consumption of tapeworm eggs.

CYSTINOSIS. A genetic disorder characterized by a buildup of an amino acid called cystine in the body. It leads to abnormal amounts of carbohydrates and amino acids in the urine, excessive urination, and low blood levels of potassium and phosphates.

CYSTITIS. Inflammation of the bladder, usually caused by bacterial infection.

CYSTOCELE. Bulging of the bladder into the vagina.

CYSTOMETRY. A test of bladder function in which pressure and volume of fluid in the bladder are measured during filling, storage, and voiding.

CYSTOSCOPE. Endoscope especially designed for urological use to examine the bladder, lower urinary tract, and prostate gland.

CYSTOSCOPY. A diagnostic procedure that uses a cystoscope to look inside the bladder and to collect samples of urine and tissue.

CYSTOURETHROCELE. Bulging of the bladder neck into the vagina.

CYTOCHROME. A substance that contains iron and acts as a hydrogen carrier for the eventual release of energy in aerobic respiration.

CYTOKINE. A protein associated with inflammation that, at high levels, may be toxic to nerve cells in the developing brain.

CYTOMEGALOVIRUS (CMV). A common human virus causing mild or no symptoms in healthy people, but permanent damage or death to an infected fetus, a transplant patient, or a person with HIV.

CYTOTOXIC DRUGS. Drugs that function by destroying cells.

D

DACRON. A synthetic polyester fiber used to surgically repair damaged sections of heart muscle and blood vessel walls.

DACRYOCYSTOGRAPHY. An x ray of the tear duct after injection of a dye that is used to help locate a blockage in the duct.

DACRYOCYSTORHINOSTOMY. A surgical procedure to drain the tear sac into the nasal passage.

DACRYOSTENOSIS. Obstruction or narrowing of the nasolacrimal duct. May be present at birth.

DARK FIELD. A microscopy technique in which light is directed at an oblique angle so that organisms appear bright against a dark background.

DAWN SIMULATION. A form of light therapy in which the patient is exposed while asleep to gradually brightening white light over a period of an hour and a half.

DEBILITATING. Weakening, or reducing the strength of.

DEBRIDEMENT. Surgical procedure in which dead or dying tissue is removed.

DEBULKING. Surgical removal of a major portion of a tumor so that there is less of the cancer left for later treatment by chemotherapy or radiation.

DECELERATION. A decrease in the fetal heart rate that can indicate inadequate blood flow through the placenta.

DECIBEL. A unit of measure for expressing the loudness of a sound. Normal speech is typically spoken in the range of about 20-50 decibels.

DECIDUOUS TEETH. The primary, baby, or milk teeth that fall out and are replaced by permanent teeth.

DECISION TREE. A decision support model used in medical and psychiatric diagnosis that consists of a tree-like chart or diagram including various symptoms, tentative diagnoses, diagnostic decisions, and their possible consequences.

DECOMPRESSION SICKNESS. A condition found in divers in which gas bubbles of nitrogen form in tissues and blood vessels as a result of decreasing surrounding pressure, such as in ascent from a dive. It may be a painful condition, especially as nitrogen bubbles invade the joints; persons stricken may walk stooped over in pain, in a bent stance that led to it being called "the bends."

DECONGESTANT. Medicines that shrink blood vessels and consequently mucus membranes. Pseudoephedrine, phenylephrine, and phenylpropanolamine are the most common.

DECORTICATION. Surgical removal of the fibrous peel that covers the lungs in third-stage empyema.

DECREASED PENETRANCE. Individuals who inherit a changed disease gene but do not develop symptoms.

DECUBITUS ULCERS. A pressure sore resulting from ulceration of the skin occurring in persons confined to bed for long periods of time.

DEEP BITE. A closed bite; a deep or excessive overbite in which the lower incisors bite too closely to or into the gum tissue or palate behind the upper teeth.

DEEP BREATHING. Helps expand the lungs and forces better distribution of the air into all sections of the lung. The patient either sits in a chair or sits upright in bed and inhales, pushing the abdomen out to force maximum amounts of air into the lung. The abdomen is then contracted, and the patient exhales.

DEEP VEIN THROMBOSIS. A blood clot in the calf's deep vein. This frequently leads to pulmonary embolism if untreated.

DEFECATE. To pass feces (stool) out of the rectum through the anus.

DEFERVESCENCE. Return to normal body temperature after high fever.

DEFIBRILLATION. An electronic process that helps re-establish a normal heart rhythm.

DEFICIENCY. A shortage of something necessary for health.

DEFICIT. In medicine, the loss or impairment of a function or ability.

DEGAS. To release and vent gases. New building materials often give off gases and odors and the air should be well circulated to remove them.

DEGENERATION. Gradual, progressive loss of nerve cells.

DEGENERATIVE. Degenerative disorders involve progressive impairment of both the structure and function of part of the body.

DEGENERATIVE ARTHRITIS, OR OSTEOARTHRITIS. A noninflammatory type of arthritis, usually occurring in older people, characterized by degeneration of cartilage, enlargement of the margins of the bones, and changes in the membranes in the joints.

DEHYDRATION. A condition in which the body lacks the normal level of fluids, potentially impairing normal body functions.

DELAYED HYPERSENSITIVITY REACTIONS. Allergic reactions mediated by T cells that occur hours to days after exposure to the antigen.

DELETION. The absence of genetic material that is normally found in a chromosome. Often, the genetic

material is missing due to an error in replication of an egg or sperm cell.

DELIRIUM. A disturbance of consciousness marked by confusion, difficulty paying attention, delusions, hallucinations, or restlessness. It can be distinguished from dementia by its relatively sudden onset and variation in the severity of the symptoms.

DELIRIUM TREMENS. A complication that may accompany alcohol withdrawal. The symptoms include body shaking (tremulousness), insomnia, agitation, confusion, hearing voices or seeing images that are not really there (hallucinations), seizures, rapid heart beat, profuse sweating, high blood pressure, and fever.

DELUSION. A false belief that is resistant to reason or contrary to fact. Common delusions include delusions of persecution, delusions about one s importance (sometimes called delusions of grandeur), or delusions of being controlled by others.

DELUSIONAL DISORDER. Individuals with delusional disorder suffer from long-term, complex delusions that fall into one of six categories: persecutory, grandiose, jealousy, erotomanic, somatic, or mixed.

DEMENTIA. A decline in a person's level of intellectual functioning. Dementia includes memory loss as well as difficulties with language, simple calculations, planning or decision-making, and motor (muscular movement) skills.

DEMYELINATING DISORDERS. A group of diseases characterized by the breakdown of myelin, the fatty sheath surrounding and insulating nerve fibers. This breakdown interferes with nerve function, and can result in paralysis. Multiple sclerosis is a demyelinating disorder.

DEMYELINATION. Disruption or destruction of the myelin sheath, leaving a bare nerve. Results in a slowing or stopping of impulses traveling along that nerve.

DENDRITES. Fibers of a brain cell that receive signals from other brain cells.

DENDRITIC CELL. A special type of antigen-presenting cell that is effective in stimulating T cells.

DENTAL CARIES. A disease of the teeth in which microorganisms convert sugar in the mouth to acid that erodes the tooth.

DENTAL LASER. A device that generates a low-powered beam of light that is used in place of a dentist's drill to cut away decay from a tooth or remove gum tissue.

DENTIN. The middle layer of a tooth, which makes up most of the tooth's mass.

DEOXYRIBONUCLEIC ACID (DNA). The genetic material in cells that holds the inherited instructions for growth, development, and cellular functioning.

DEPENDENCE. A state in which a person requires a steady concentration of a particular substance to avoid experiencing withdrawal symptoms.

DEPERSONALIZATION. A dissociative symptom in which the patient feels that his or her body is unreal, is changing, or is dissolving.

DEPOLARIZATION. A change in a cell's membrane potential, making its electrical charge more positive or less negative. Defibrillation essentially depolarizes a portion of the heart muscle, allowing the heart's natural pacemaker to reestablish normal heart rhythm.

DEPOT DOSAGE. A form of medication that can be stored in the patient's body tissues for several days or weeks, thus minimizing the risk of the patient forgetting daily doses. Haloperidol and fluphenazine can be given in depot form.

DEPRESSION. A mental condition in which a person feels extremely sad and loses interest in life. A person with depression may also have sleep problems and loss of appetite and may have trouble concentrating and carrying out everyday activities. Severe depression may instigate a suicide attempt.

DEPRIVATION. A condition of having too little of something.

DEPRIVATIONAL DWARFISM. A condition where emotional disturbances are associated with growth failure and abnormalities of pituitary function.

DEREALIZATION. A dissociative symptom in which the external environment is perceived as unreal.

DERMABRASION. A technique for removing the upper layers of skin with planing wheels powered by compressed air.

DERMATITIS. A skin condition characterized by a red, itchy rash. It may occur when the skin comes in contact with something to which it is sensitive.

DERMATITIS HERPETIFORMIS. A chronic very itchy skin disease with groups of red lesions that leave spots behind when they heal. It is sometimes associated with cancer of an internal organ.

DERMATOLOGIST. A doctor who specializes in diagnosing and treating diseases of the skin.

DERMATOLOGY. The branch of medicine that studies and treats disorders of the skin.

DERMATOPHYTE. The medical name for three genera of fungi that cause ringworm in humans and domestic pets. The name is derived from two Greek words that mean "skin" and "plant."

DERMATOSIS. A noninflammatory skin disorder.

DERMATOSPARAXIS. Skin fragility caused by abnormal collagen.

DERMIS. The basal layer of skin; it contains blood and lymphatic vessels, nerves, glands, and hair follicles.

DERMOID. A skin-like benign growth that may appear on the ovary and resemble a cyst.

DESENSITIZATION. The elimination of an emotional response, such as fear or anxiety, to specific stimuli.; or, a technique of pain reduction in which the painful area is stimulated with whatever is causing the pain.

DESFEROXAMINE. The primary drug used in iron chelation therapy. It aids in counteracting the life–threatening buildup of iron in the body associated with long–term blood transfusions.

DESICCATION. Tissue death.

DESMOPRESSIN (DDAVP). A drug used in the treatment of von Willebrand's disease.

DESQUAMATION. Shedding of the cells lining the insides of the air sacs. A feature of desquamative interstitial pneumonitis.

DETOXIFICATION. A process of altering the chemical structure of a compound to make it less toxic.

DETRUSOR MUSCLE. Bladder muscle.

DEVELOPMENTAL. Referring to a speech problem or other disorder that arises during a specific stage in human development.

DEVELOPMENTAL DAMAGE. A term that some therapists prefer to personality disorder, on the grounds that it is more respectful of the patient's capacity for growth and change.

DEVELOPMENTAL DELAY. The failure to meet certain developmental milestones, such as sitting, walking, and talking, at the average age. Developmental delay may indicate a problem in development of the central nervous system.

DEVIATED SEPTUM. A hole or perforation in the septum, the wall that divides the two nasal cavities.

DEXA BONE DENSITY SCAN. A bone density scan that uses a rotating x-ray beam to measure the strength of an individual's bones and his or her fracture risk.

DEXAMETHASONE TEST. A test that serves as a marker of suicide risk by reflecting signaling activity between the brain and the adrenal gland.

DIABETES. A disease characterized by an inability to process sugars in the diet, due to a decrease in or total absence of insulin production. May require injections of insulin before meals to aid in the metabolism of sugars.

DIABETES INSIPIDUS. A metabolic disorder in which the pituitary gland produces inadequate amounts of antidiuretic hormone (ADH) or the kidneys are unable to respond adequately to ADH. Primary symptoms are excessive urination and constant thirst.

DIABETES MELLITUS. A disease in which insufficient insulin is made by the body to metabolize sugars.

DIABETIC COMA. Reduced level of consciousness that requires immediate medical attention.

DIABETIC KETOACIDOSIS. A condition caused by low insulin levels where the amount of sugar and ketones in the blood is high.

DIABETIC PERIPHERAL NEUROPATHY. A condition in which the sensitivity of nerves to pain, temperature, and pressure is dulled, particularly in the legs and feet.

DIABETIC RETINOPATHY. A condition in which the tiny blood vessels to the retina, the tissues that sense light at the back of the eye, are damaged, leading to blurred vision, sudden blindness, or black spots, lines, or flashing lights in the field of vision.

DIAGNOSTIC TESTING. Testing performed to determine if someone is affected with a particular disease.

DIAGNOSTIC WINDOW. A cardiac marker's timeline for rising, peaking, and returning to normal after a heart attack.

DIALECTICAL BEHAVIOR THERAPY. A type of cognitive-behavioral therapy designed specifically to treat borderline personality disorder.

DIALYSATE. A chemical bath used in dialysis to draw fluids and toxins out of the bloodstream and supply electrolytes and other chemicals to the bloodstream.

DIALYSIS. A blood filtration therapy that replaces the function of the kidneys, filtering fluids, and waste

products out of the bloodstream. There are two types of dialysis treatment: hemodialysis, which uses an artificial kidney, or dialyzer, as a blood filter; and peritoneal dialysis, which uses the patient's abdominal cavity (peritoneum) as a blood filter.

DIALYZER. An artificial kidney usually composed of hollow fiber which is used in hemodialysis to eliminate waste products from the blood and remove excess fluids from the bloodstream.

DIAPHRAGM. A sheet of muscle tissue that divides the chest cavity from the abdominal cavity; or a dome-shaped device used to cover the back of a woman's vagina during intercourse in order to prevent pregnancy.

DIAPHRAGM BREATHING. Method of deep breathing using the entire lungs.

DIARRHEA. Abnormally frequent bowel movements with fluid stools.

DIASTOLE. Period between contractions of the heart.

DIASTOLIC. The phase of blood circulation in which the heart's pumping chambers (ventricles) are being filled with blood. During this phase, the ventricles are at their most relaxed, and the pressure against the walls of the arteries is at its lowest.

DIATHERMY. Also called electrocautery, this is a procedure that heats and destroys abnormal cells.

DIATHESIS. The medical term for predisposition. The stress/diathesis model is a diagram that is used to explain why some people are at greater risk of suicidal behavior than others.

DIAZEPAM. One of the most commonly used sedative-hypnotic medications.

DIENCEPHALON. A part of the brain that binds the mesencephalon to the cerebral hemispheres. Considered by some as part of the brain stem.

DIETARY SUPPLEMENT. A product, such as a vitamin, mineral, herb, amino acid, or enzyme, intended to be consumed in addition to an individual's diet with the expectation that it will improve health.

DIETHYLSTILBESTROL (DES). A synthetic form of estrogen that was widely prescribed to women from 1940 to 1970 to prevent complications during pregnancy, and linked to several serious birth defects and disorders of the reproductive system in daughters of women who took DES.

DIETITIAN. A health care professional who specializes in individual or group nutritional planning, public education in nutrition, or research in food science. To be licensed as a registered dietitian (RD) in the United States, a person must complete a bachelor's degree in a nutrition-related field and pass a state licensing examination. Dietitians are also called nutritionists.

DIFFERENTIAL. A blood cell count in which the percentages of cell types are calculated as well as the total number of cells.

DIFFERENTIAL DIAGNOSIS. Comparing and contrasting the signs, symptoms, and laboratory findings of two or more diseases to determine which is causing the patient's condition.

DIFFERENTIATION. The ability to retain one's identity within a family system while maintaining emotional connections with the other members.

DIFFUSION TENSOR IMAGING (DTI). A refinement of magnetic resonance imaging that allows the doctor to measure the flow of water and track the pathways of white matter in the brain. DTI is able to detect abnormalities in the brain that do not show up on standard MRI scans.

DIGESTION. The mechanical, chemical, and enzymatic process in which food is converted into the materials suitable for use by the body.

DIGESTIVE ENZYMES. Molecules that catalyze the breakdown of large molecules (usually food) into smaller molecules.

DIGESTIVE TRACT. The stomach, intestines, and other parts of the body through which food passes.

DIGIT. A finger or a toe.

DIGITAL RECTAL EXAMINATION. A routine screening test that is used to detect any lumps in the prostate gland or any hardening or other abnormality of the prostate tissue. The doctor inserts a gloved and lubricated finger (digit) into the patient's rectum, which lies just behind the prostate.

DIGITALIS. A drug that helps the heart muscle to have stronger pumping action.

DIHYDROXYACETONE (DHA). A chemical used for staining the skin to simulate a tan.

DILATE. To enlarge, open wide, or distend.

DILATED CARDIOMYOPATHY. Also called congestive cardiomyopathy; cardiomyopathy in which the walls of the heart chambers stretch, enlarging the

heart ventricles so they can hold a greater volume of blood than normal.

DILATATION AND CURETTAGE (D & C). A procedure in which the doctor opens the cervix and uses a special instrument to scrape tissue from the inside of the uterus.

DILUTE. A solution that has comparatively more fluid in it, relative to the quantity of solute.

DIMERCAPROL (BAL). A chemical agent used to remove excess lead from the body.

DIOPTER (D). A unit of measure for describing refractive power.

DIPHTHERIA–TETANUS–PERTUSSIS (DTP). The standard preparation used to immunize children against diphtheria, tetanus, and whooping cough. A so–called "acellular pertussis" vaccine (aP) is usually used since its release in the mid–1990s in a combined vaccine known as DTaP.

DIPHTHERIA. A serious, infectious disease that produces a toxin (poison) and an inflammation in the membrane lining of the throat, nose, trachea, and other tissues.

DIPHYLLOBOTHRIASIS. Parasitic infection caused by the presence of tapeworms from the *Diphyllobothrium* genus, such as the fish tapeworm (*Diphyllobothrium latum*).

DIPLEGIA. Paralysis affecting like parts on both sides the body, such as both arms or both legs.

DIPLOPIA. The medical term for seeing double.

DIRECT CURRENT (DC). An electric current in which the electric charge moves in only one direction. It is the type of current produced by batteries and solar cells.

DIRECTION. Bringing about the free balance of the head on the spine and the resulting release of the erector muscles of the back and legs which establish improved coordination.

DISACCHARIDE. Any sugar formed when two monosaccharides are joined together and a molecule of water is removed.

DISCHARGE PLANNER. A health-care professional who helps patients arrange for health and home care needs after they go home from the hospital.

DISEASE MODIFYING ANTI-RHEUMATIC DRUGS (DMARDS). A class of antirheumatic drugs, including chloroquine, methotrexate, cyclosporine, and gold compounds, that influence the disease process itself and do not only treat its symptoms.

DISENFRANCHISED GRIEF. Grief that cannot be openly expressed because the death or other loss cannot be publicly acknowledged.

DISEQUILIBRIUM. Difficulty with equilibrium that can mean a deficiency in balance and/or orientation.

DISFLUENCY. Any difficulty in fluent speech, including stuttering.

DISINFECTED. Decreased the number of microorganisms on or in an object.

DISK. A ringlike structure that fits between the vertebrae in the spine to protect the bones, nerves, and blood vessels. The outer layer is a tough, fibrous tissue, and the inner core is composed of more elastic tissue.

DISKECTOMY. The surgical removal of a portion of an intervertebral disk.

DISLOCATION. Displacement of bones at a joint.

DISPERSANT. Chemicals that break up spilled oil into small particles that can be further scattered and broken down by water and wind, thus sparing oil damage to marine and coastal environments.

DISPLACEMENT. A psychological process in which feelings originating from one source are expressed outwardly in terms of concern or preoccupation with an issue or problem that the individual considers more acceptable.

DISSECTION. A cut or divide.

DISSEMINATED INTRAVASCULAR COAGULATION (DIC). A condition in which spontaneous bleeding and clot formation occur throughout the circulatory system. DIC can be caused by transfusion reactions and a number of serious illnesses.

DISSOCIATION. A psychological mechanism in which the mind splits off certain aspects of a traumatic event from conscious awareness. Dissociation can affect the patient's memory, sense of reality, and sense of identity.

DISSOCIATIVE DISORDERS. A group of mental disorders in which dissociation is a prominent symptom. Patients with dissociative disorders have a high rate of self-mutilation.

DISSOCIATIVE IDENTITY DISORDER (DID). Term that replaced Multiple Personality Disorder (MPD). A condition in which two or more distinctive identities or personality states alternate in controlling a person's consciousness and behavior.

DISTAL MUSCULAR DYSTROPHY (DD). A form of muscular dystrophy that usually begins in middle age or later, causing weakness in the muscles of the feet and hands.

DISTAL PHALANX. The outermost bone of any finger or toe.

DISTAL TUBULE. The portion of the kidney tubule that lies furthest away from the point at which fluid from the blood enters the tubule.

DISULFIRAM. A medication that has been used since the late 1940s as part of a treatment plan for alcohol abuse. Disulfiram, which is sold under the trade name Antabuse, produces changes in the body's metabolism of alcohol that cause headaches, vomiting, and other unpleasant symptoms if the patient drinks even small amounts of alcohol.

DIURETIC. A drug designed to encourage excretion of urine in people who accumulate excess fluid such as individuals with high blood pressure or heart conditions.

DIURETIC AGENT. A drug which increases urine output.

DIVERTICULA. Abnormal pouches of tissue that bulge off the main part of the digestive system.

DIVERTICULITIS. A condition of the diverticulum of the intestinal tract, especially in the colon, where inflammation may cause distended sacs extending from the colon and pain.

DIVERTICULOSIS. A condition in which the colon (large intestine) develops a number of outpouchings or sacs.

DIVERTICULUM. A pouch extending from a hollow organ.

DNA (DEOXYRIBONUCLEIC ACID). The hereditary material that makes up genes; influences the development and functioning of the body.

DNA PROBE. An agent that binds directly to a predefined sequence of nucleic acids.

DNA TESTING. Analysis of DNA (the genetic component of cells) in order to determine changes in genes that may indicate a specific disorder.

DOMINANT INHERITANCE. A pattern of inheritance in which a trait or disease is conferred by one gene or allele. A parent with a disorder caused by a dominant allele has a 50% chance of passing the trait for disease to their offspring.

DOMINANT TRAIT. A genetic trait in which one copy of the gene is sufficient to yield an outward display of the trait; dominant genes mask the presence of recessive genes; dominant traits can be inherited from a single parent.

DONEPEZIL HYDROCHLORIDE (ARICEPT). A drug that increases the levels of acetylcholine in the brain.

DONOR. A person who supplies organ(s), tissue or blood to another person for transplantation.

DONOVAN BODIES. Rod-shaped oval organisms found in tissue samples from patients with granuloma inguinale. Donovan bodies appear deep purple when stained with Wright's stain.

DOPA. The common name for a natural chemical (3, 4-dihydroxyphenylalanine) made by the body during the process of making melanin.

DOPAMINE. A neurochemical made in the brain that is involved in many brain activities, including movement and emotion.

DOPAMINE RECEPTOR ANTAGONISTS (DAS). The older class of antipsychotic medications, also called neuroleptics. These primarily block the site on nerve cells that normally receive the brain chemical dopamine.

DOPPLER EFFECT. The principle that the sound of an object moving toward you has a higher pitch than the sound when it is moving away from you.

DOPPLER SCANNING. A procedure in which ultrasound images are used to watch a moving structure such as the flow of blood or the beating of the heart.

DOPPLER ULTRASOUND. An imaging technique that can detect moving fluids.

DORSAL. Referring to a position closer to the back than to the stomach. The laminae in the spinal column are located on the dorsal side of each vertebra.

DORSAL RHIZOTOMY. A surgical procedure that cuts nerve roots to reduce spasticity in affected muscles.

DORSAL ROOT ENTRY ZONE (DREZ). A type of nerve surgery for postherpetic neuralgia that is occasionally used when the patient can get no other pain relief. The surgery destroys the area where damaged nerves join the central nervous system, thereby interfering with inappropriate pain messages from nerves to the brain.

DOSHA. One of three constitutional types, either vata, pitta, or kapha, found in Ayurvedic medicine.

DOWN SYNDROME. A chromosomal disorder caused by an extra copy or a rearrangement of chromosome 21. Children with Down syndrome have

varying degrees of mental retardation and may have heart defects.

DRUG INTERACTION. A chemical or physiological reaction that can occur when two different drugs are taken together.

DRUSEN. Clumps of pigment that accumulate under the retina when wastes build up faster than they can be removed. Drusen are a sign of dry age-related macular degeneration.

DRY SOCKET. A painful condition following tooth extraction in which a blood clot does not properly fill the empty socket, leaving the bone underneath exposed to air and food.

DUBOWITZ EXAM. A standardized test that scores responses to 33 specific neurological stimuli to estimate an infant's neural development and, hence, gestational age.

DUCHENNE MUSCULAR DYSTROPHY (DMD). The most severe form of muscular dystrophy, DMD usually affects young boys and causes progressive muscle weakness, usually beginning in the legs.

DUCT. A tube through which various substances can pass. These substances can travel through ducts to another organ or into the bloodstream.

DUCTAL ADENOCARCINOMA. A malignant tumor arising from the duct cells within a gland.

DUCTAL CARCINOMA. A type of cancer that accounts for as much as 80% of breast cancers. These tumors feel bigger than they look on ultrasound or mammogram.

DUCTUS. The blood vessel that joins the pulmonary artery and the aorta. When the ductus does not close at birth, it causes a type of congenital heart disease called patent ductus arteriosus.

DUCTUS ARTERIOSUS. The temporary channel or blood vessel between the aorta and pulmonary artery in the fetus.

DUODENAL. Pertaining to the first part of the small intestine.

DUODENAL ATRESIA. Closure or blockage of the duodenum, the upper section of the small intestine.

DUPUYTREN'S CONTRACTURE. Shortening and thickening of connective tissue in the palm causing the fingers to pull in.

DURA. A tough fibrous membrane that covers and protects the spinal cord.

DURA MATER. One of the membranes that sheathes the spinal cord and brain; the outermost layer.

DWARFISM. A congenital disease of bone growth that results in short stature and weak bones.

DYANA. The yoga term for meditation.

DYSBIOSIS. The condition that results when the natural flora of the gut are thrown out of balance, such as when antibiotics are taken.

DYSENTERY. A type of diarrhea caused by infection and characterized by mucus and blood in the stools.

DYSKINESIA. Impaired ability to make voluntary movements.

DYSLEXIA. An inability to read, write, or spell words in spite of the ability to see and recognize letters. Dyslexia is an autosomal dominant disorder thst occurs more frequently in males.

DYSMENORRHEA. Painful menstruation.

DYSPAREUNIA. Difficult or painful sexual intercourse.

DYSPEPSIA. A vague feeling of being too full and having heartburn, bloating, and nausea. Usually felt after eating.

DYSPHAGIA. Difficult or painful swallowing.

DYSPHORIA. A depressed and anxious mood state.

DYSPLASTIC NEVUS SYNDROME. A familial syndrome characterized by the presence of multiple atypical appearing moles, often at a young age.

DYSPNEA. A difficulty in breathing or shortness of breath, typically associated with some form of heart or lung disease. Also known as air hunger.

DYSSOMNIA. A primary sleep disorder in which the patient suffers from changes in the quantity, quality, or timing of sleep.

DYSTHYMIA. Type of affective disorder or mood disorder that often resembles a less severe, yet more chronic form of major.

DYSTOCIA. Failure to progress in labor, either because the cervix will not dilate (expand) further or (after full dilation) the head does not descend through the mother's pelvis.

DYSTROPHIN. A protein that helps muscle tissue repair itself. Both Duchenne muscular dystrophy and Becker muscular dystrophy are caused by flaws in the gene that instructs the body how to make this protein.

DYSURIA. Painful or difficult urination.

E

EAR CANDLING. An alternative method for removing impacted cerumen with a lighted hollow cone of paraffin or beeswax. It does not work, and is not considered an acceptable treatment for any ear problem or disorder.

EAR SPECULUM. A cone- or funnel-shaped attachment for an otoscope which is inserted into the ear canal to examine the eardrum.

EARDRUM. A paper-thin covering stretching across the ear canal that separates the middle and outer ears.

EATING DISORDER. A condition characterized by an abnormal attitude towards food, altered appetite control, and unhealthy eating habits that affect health and the ability to function normally.

EBOLA. The disease caused by the newly described and very deadly Ebola virus found in Africa.

ECCHYMOSIS (PLURAL, ECCHYMOSES). The medical term for a bruise. Ecchymoses may develop around the eyes following a nasal fracture.

ECG OR EKG. A record of the waves that relate to the electrical impulses produced at each beat of the heart.

ECHOCARDIOGRAM. A non-invasive imaging procedure used to create a picture of the heart's movement, valves, and chambers.

ECHOCARDIOGRAPH. A record of the internal structures of the heart obtained from beams of ultrasonic waves directed through the wall of the chest.

ECHOCARDIOGRAPHY. A diagnostic instrument that assesses the structure of the heart using sound waves.

ECHOLALIA. Involuntary echoing of the last word, phrase, or sentence spoken by someone else.

ECHOPRAXIA. The imitation of the movement of another individual.

ECTOPIA LENTIS. Dislocation of the lens of the eye. It is one of the most important single indicators in diagnosing Marfan syndrome.

ECTOPIC BEAT. Abnormal heart beat arising elsewhere than from the sinoatrial node.

ECTOPIC PARATHYROID TISSUE. A condition where the thyroid tissue is located in an abnormal place.

ECTOPIC PREGNANCY. A pregnancy in which the fertilized egg has implanted outside the uterus, most often in the Fallopian tubes, although in some cases the pregnancy implants in the ovary or in the abdomen.

ECZEMA. A disease in which the skin becomes dry, red, itchy, and thickened.

EDEMA. A condition where tissues contain excessive fluid.

EDETATE CALCIUM DISODIUM (EDTA CALCIUM). A chemical agent used to remove excess lead from the body.

EDTA. A colorless compound used to keep blood samples from clotting before tests are run. Its chemical name is ethylenediaminetetraacetic acid.

EFFACEMENT. The thinning out of the cervix that normally occurs along with dilation shortly before delivery.

EFFERENT. Refers to peripheral nerves that carry signals away from the brain and spinal cord. These nerves carry out motor and autonomic functions.

EFFERENT NERVES. Nerves that convey impulses away from the central nervous system to the periphery.

EFFUSION. A collection of fluid which has leaked out into some body cavity or tissue.

EGO–SYNTONIC. Consistent with one's sense of self, as opposed to ego–alien or dystonic (foreign to one's sense of self). Ego–syntonic traits typify patients with personality disorders.

EHLERS-DANLOS SYNDROME. A rare inheritable disease of the connective tissue marked by very elastic skin, very loose joints, and very fragile body tissue.

EIGHTH CRANIAL NERVE DISEASE. A disorder affecting the eighth cranial nerve, characterized by a loss of hearing and/or balance.

EJACULATION. The act of expelling the sperm through the penis during orgasm.

EJACULATORY INCOMPETENCE. The inability to ejaculate within the vagina.

EJECTION FRACTION. A measure of the portion of blood that is pumped out of a filled ventricle.

EKG. A tracing of the electrical activity of the heart.

ELASTIC FIBER. Fibrous, stretchable connective tissue made primarily from proteins, elastin, collagen, and fibrillin.

ELECTOLYTES. Salts, such as sodium and chloride.

ELECTROCARDIOGRAPHY (ECG). A test of a patient's heartbeat that involves placing leads, or detectors, on the patient's chest to record electrical impulses in the heart. The test will produce a strip, or picture record of the heart's electrical function.

ELECTROCOAGULATION. The coagulation or destruction of tissue through the application of a high-frequency electrical current.

ELECTROCONVULSIVE THERAPY (ECT). Therapy for mood disorders that involves passing electrical current through the brain in order to create a brief convulsion.

ELECTRODES. Tiny wires in adhesive pads that are applied to the body for ECG measurement.

ELECTRODESICCATION. To make dry, dull, or lifeless with the use of electrical current.

ELECTROENCEPHALOGRAPHY (EEG). The recording of the tiny electrical impulses produced by the brain's activity. By measuring characteristic wave patterns, the EEG can help diagnose certain conditions of the brain.

ELECTROLYTE. An ion such as potassium, sodium, or chloride dissolved in fluid that helps to regulate metabolic activities of cells; or A substance that conducts electric current within the body and is essential for sustaining life.

ELECTROMYOGRAPHIC BIOFEEDBACK. A method for relieving jaw tightness by monitoring the patient's attempts to relax the muscle while the patient watches a gauge. The patient gradually learns to control the degree of muscle relaxation.

ELECTROMYOGRAPHY (EMG). A test that uses electrodes to record the electrical activity of muscle. The information gathered is used to diagnose neuromuscular disorders.

ELECTRON. An elementary particle carrying a negative charge. Electrons may exist either independently or as components of an atom outside its nucleus.

ELECTRONIC FETAL NONSTRESS TEST. A test in which electronic monitors attached to the mother's abdomen to detect contractions of the uterus as well as the baby's heartbeat and movements.

ELECTRONYSTAGMOGRAPHY. A method for measuring the electricity generated by eye movements. Electrodes are placed on the skin around the eye and the individual is subjected to a variety of stimuli so that the quality of eye movements can be assessed.

ELECTROPHORESIS. A method of separating complex protein molecules suspended in a gel by running an electric current through the gel.

ELECTROPHYSIOLOGICAL STUDY. A test that monitors the electrical activity of the heart in order to diagnose arrhythmia. An electrophysiological study measures electrical signals through a cardiac catheter that is inserted into an artery in the leg and guided up into the atrium and ventricle of the heart.

ELECTROPHYSIOLOGY. Study of how electrical signals in the body relate to physiologic function.

ELECTROSURGICAL DEVICE. A medical device that uses electrical current to cauterize or coagulate tissue during surgical procedures, often used in conjunction with laparoscopy, colonoscopy, or sigmoidoscopy.

ELECTROTHERAPY. The treatment of body tissues by passing electrical currents through them, stimulating the nerves and muscles.

ELEMENTAL MERCURY; HG. Metallic mercury; quicksilver; a heavy, silvery, poisonous metallic element that is a liquid at room temperature but vaporizes readily.

ELEPHANTIASIS. A condition characterized by the gross enlargement of limbs and/or the genitalia that is also accompanied by a hardening and stretching of the overlying skin. Often a result of an obstruction in the lymphatic system caused by infection with a filarial worm.

ELISA. Enzyme-linked immunosorbent assay; a screening test that uses antibodies to detect infections such as gonorrhea and HIV.

ELIXIR. Liquid that contains alcohol, water, and a therapeutic agent.

EMBOLISM. The blocking of the flow of blood in an artery by an embolus. When an embolism blocks the blood supply to a tissue or organ, the tissue the artery feeds dies (infarction). Without immediate and appropriate treatment, an embolism can be fatal.

EMBOLIZATION. A technique for stopping bleeding by introducing a substance into larger blood vessels that blocks or closes them.

EMBOLUS (PLURAL, EMBOLI). A gas or air bubble, bit of tissue, blood clot, or foreign object that circulates in the bloodstream until it lodges in a vessel. A large embolus can narrow or block the vessel, which leads to decreased blood flow in the organ supplied by that vessel.

EMBRYO. A developing human from the time of conception to the end of the eighth week after conception.

EMBRYONIC. Early stages of life in the womb.

EMERGENCY CONTRACEPTIVE PILLS; ECPS. Medication containing synthetic hormones for preventing pregnancy after unprotected vaginal intercourse.

EMESIS. The medical term for vomiting.

EMETIC. A medication or substance given to induce vomiting.

EMLA. Eutectic mixture of local anesthetics, a drug combination for use on intact skin.

EMMENAGOGUE. A medication or herbal preparation given to bring on a woman's menstrual period.

EMOLLIENT. A paste or compound having a soothing effect when applied to the skin.

EMOTIONAL CONDITIONING. The memory system that links perceptual information to an emotional response. For example, spotting a friend in a crowd causes a person to feel happy.

EMPHYSEMA. A chronic disease characterized by loss of elasticity and abnormal accumulation of air in lung tissue.

EMPIRICAL TREATMENT. Medical treatment that is given on the basis of the doctor's observations and experience.

EMPYEMA. An accumulation of pus in the lung cavity, usually as a result of infection.

ENAMEL. The hard outer surface of a tooth.

ENCEPHALITIS. A rare viral infection that causes inflammation in the membranes lining the brain.

ENCEPHALOCELES. Protrusion of the brain through a defect in the skull.

ENCEPHALOPATHY. A dysfunction of the brain. Hepatic encephalopathy is brain dysfunction that occurs because the liver isn't removing harmful substances from the blood.

ENCOPRESIS. Abnormalities relating to bowel movements that can occur as a result of stress or fear.

ENCYSTED. Enclosed in a cyst or capsule. Flukes spend part of their life cycle as encysted larvae.

END-STAGE HEART FAILURE. Severe heart disease that does not respond adequately to medical or surgical treatment.

END-STAGE LUNG DISEASE. The final stages of lung disease, when the lung can no longer keep the blood supplied with oxygen. End-stage lungs in pulmonary fibrosis have large air spaces separated by bands of inflammation and scarring.

END-STAGE RENAL DISEASE (ESRD). Total kidney failure; chronic kidney failure is diagnosed as ESRD when kidney function falls to 5-10% of capacity.

ENDARTERECTOMY. A surgical procedure in which diseased tissue and atherosclerotic plaque are removed from the inside of an artery.

ENDARTERITIS. Chronic inflammation of the inner layer of arteries.

ENDEMIC. A condition that is always present in a given population, such as human lice infestation.

ENDEMIC AREA. A geographical area where a particular disease is prevalent.

ENDEMIC DISEASE. An infectious disease that occurs frequently in a specific geographical locale. The disease often occurs in cycles. Influenza is an example of an endemic disease.

ENDOCARDITIS. A dangerous infection of the heart valves caused by certain bacteria.

ENDOCARDIUM. The inner wall of the heart muscle, which also covers the heart valves.

ENDOCERVICAL CURETTAGE. Biopsy performed with a curette to scrape the mucous membrane of the cervical canal.

ENDOCRINE. A system of organs that produces chemicals that go into the bloodstream to reach other organs whose functioning they affect.

ENDOCRINE GLAND. A ductless gland, such as the pituitary, thyroid, or adrenal gland, that secretes its products directly into the blood or lymph.

ENDOCRINE SYSTEM. A system of ductless glands that secrete hormones that regulate a variety of body processes, including growth and sexual maturation. A doctor who specializes in diseases and disorders of these glands is called an endocrinologist.

ENDOCRINOLOGIST. A doctor who specializes in diagnosing and treating disorders of the endocrine glands and the hormones they secrete.

ENDODONTIC. Pertaining to the inside structures of the tooth, including the dental pulp and tooth root, and the periapical tissue surrounding the root.

ENDODONTIST. A dentist who specializes in diagnosing and treating diseases of the pulp and other inner parts of the tooth.

ENDOMETRIAL BIOPSY. A procedure in which a sample of the endometrium is removed and examined under a microscope.

ENDOMETRIAL CANCER. Cancer of the inner mucous membrane of the uterus.

ENDOMETRIAL IMPLANTS. Growths of endometrial tissue that attach to organs, primarily in the pelvic cavity.

ENDOMETRIAL POLYPS. A growth in the lining of the uterus (endometrium) that may cause bleeding and can develop into cancer.

ENDOMETRIOMA. A type of cyst formed when endometrial tissue grows within the ovary.

ENDOMETRIOSIS. A benign condition that occurs when cells from the lining of the uterus begin growing outside the uterus.

ENDOMETRITIS. Inflammation of the endometrium or mucous membrane of the uterus.

ENDOMETRIUM. The layer lining the inner cavity of the uterus; this layer changes daily throughout the menstrual cycle.

ENDOMYOCARDIAL BIOPSY. Removal of a small sample of heart tissue to check it for signs of damage caused by organ rejection.

ENDOPHTHALMITIS. Inflammation of the eyeball.

ENDORPHINS. A class of peptides in the brain that are produced during exercise and bind to opiate receptors, resulting in pleasant feelings and pain relief.

ENDOSCOPE. A medical instrument that can be passed into an area of the body (e.g., the bladder or intestine) to allow examination of that area. The endoscope usually has a fiber-optic camera, which allows a greatly magnified image to be shown on a television screen viewed by the operator.

ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY. A diagnostic procedure for mapping the pancreatic and common bile ducts. A flexible tube with a light transmitter (fiberoptics) is placed in the duct. A contrast dye is instilled directly into the duct and a series of x-ray images are taken.

ENDOSCOPIC TUBE. A tube that is inserted into a hollow organ permitting a physician to see the inside it.

ENDOSCOPIC ULTRASONOGRAPHY (EUS). Diagnostic imaging technique in which an ultrasound probe is inserted down a patient's throat to determine if a tumor is present.

ENDOSCOPY. A diagnostic procedure in which a tube is inserted through the mouth, into the esophagus and stomach. It is used to visualize various digestive disorders, including hiatal hernias.

ENDOSTEAL IMPLANTS. Dental implants that are placed within the bone.

ENDOTHELIAL CELLS. The cells lining the inner walls of the blood vessels.

ENDOTHELIAL. Referring to the endothelium, the layer of cells that lines body cavities and vessels.

ENDOTRACHEAL TUBE. A hollow tube that is inserted into the windpipe (trachea), leading to the lungs.

ENDOVASCULAR GRAFTING. A procedure that involves the insertion of a delivery catheter through a groin artery into the abdominal aorta under fluoroscopic guidance.

ENEMA. Insertion of a tube into the rectum to infuse fluid into the bowel and encourage a bowel movement. Ordinary enemas contain tap water, mixtures of soap and water, glycerine and water, or other materials.

ENGRAFTMENT. The process of transplanted stem cells reproducing new cells.

ENKEPHALINES. Peptide produced by the body that have analgesic properties.

ENOPHTHALMOS. A condition in which the eye falls back into the socket and inhibits proper eyelid function.

ENTERAL NUTRITION. Liquid nutrition provided through tubes that enter the gastrointestinal tract, usually through the mouth or nose.

ENTERIC. Pertaining to the intestine.

ENTERIC FEVER. A term that is sometimes used for either typhoid or paratyphoid fever.

ENTEROCELE. Bulging of the intestine into the upper part of the vagina.

ENTEROSTOMAL THERAPIST (ET). A specialized counselor, usually a registered nurse, who provides ostomy patients with education and counseling before the operation. After surgery, the ET helps the patient learn to take care of the stoma and appliance, and offers long-term emotional support.

ENTEROTOXIGENIC. Refers to an organism that produces toxins in the gastrointestinal tract that cause such things as vomiting, diarrhea, and other symptoms of food poisoning.

ENTEROTOXIN. A type of harmful protein released by bacteria and other disease agents that affects the tissues lining the intestines.

ENTEROVIRUS. Any of a group of viruses that primarily affect the gastrointestinal tract.

ENTRAINMENT. The patterning of body processes and movements to the rhythm of music.

ENUCLEATION. Surgical removal of the eyeball.

ENVENOMATION. Exposure to venom by bites or stings from insects, reptiles, and fish.

ENZYMATIC REPLACEMENT THERAPY. A treatment method used to replace missing enzymes. It is possible to synthesize enzymes and then inject them intravenously into patients.

ENZYME. A biological catalyst that increases the rate of a chemical reaction without being used up in the reaction.

ENZYME ACTIVITY. A measure of the ability of an enzyme to catalyze a specific reaction.

ENZYME-LINKED IMMUNOSORBENT ASSAY (ELISA). A diagnostic blood test used to screen patients for AIDS or other viruses. The patient's blood is mixed with antigen attached to a plastic tube or bead surface. A sample of the patient's blood serum is added, and excess proteins are removed. A second antibody coupled to an enzyme is added, followed by a chemical that will cause a color reaction that can be measured by a special instrument.

EOSINOPHIL. A type of white blood cell containing granules that can be stained by eosin (a chemical that produces a red stain).

EOSINOPHILIA. An abnormal increase in the number of a specific type of white blood cell. Eosinophilia is a characteristic of all types of roundworm infections.

EPHEDRINE. A sympathomimetic amine from plants of the genus *Ephedra* or chemically synthesized; an asthma medication that previously was used in weight loss drugs.

EPI-LASIK. A surgical procedure that uses a blunt, plastic oscillating blade called an epithelial separator to cut a flap in the cornea.

EPICONDYLE. A projection on the surface of a bone; often an area for muscle and tendon attachment.

EPICONDYLITIS. A painful and sometimes disabling inflammation of the muscle and surrounding tissues of the elbow caused by repeated stress and strain on the forearm near the lateral epicondyle of the humerus (arm bone).

EPIDEMIC. A large number of cases of the same disease or infection all occurring within a short time period in a specific location.

EPIDEMIC PAROTITIS. The medical name for mumps.

EPIDEMIOLOGY. The branch of medicine that deals with the transmission of infectious diseases in large populations and with detection of the sources and causes of epidemics.

EPIDERMAL. Referring to the thin outermost layer of the skin, itself made up of several layers, that covers and protects the underlying dermis (skin).

EPIDERMOLYTIC. Damaging to the top layer of skin.

EPIDIDYMO-ORCHITIS. Inflammation of both the testes and a part of the spermatic duct system.

EPIDURAL ANESTHESIA. A method of pain relief for surgery in which local anesthetic is injected into the epidural space in the middle and lower back.

EPIDURAL SPACE. The space surrounding the spinal fluid sac.

EPIGLOTTIS. A leaf-like piece of cartilage extending upwards from the larynx, which can close like a lid over the trachea to prevent the airway from receiving any food or liquid being swallowed.

EPIKERATOPHAKIA. A procedure in which the donor cornea is attached directly onto the host cornea.

EPILEPSY. A brain disorder with symptoms that include seizures.

EPILEPTOLOGIST. A physician who specializes in the treatment of epilepsy.

EPINEPHRINE. A hormone produced by the adrenal medulla. It is important in the response to stress and partially regulates heart rate and metabolism. It is also called adrenaline.

EPISIOTOMY. Incision of the perineum, the area between the vulva and the anus, to assist delivery and avoid severe tearing of the perineum.

EPISTAXIS. The medical term for a nosebleed.

EPITHELIAL. Referring to the epithelium, the layer of cells forming the epidermis of the skin and the surface layer of mucous membranes.

EPITHELIAL CELLS. Cells that form a thin surface coating on the outside of a body structure.

EPITHELIUM. Cells composing the lining of an organ.

EPITOPE. A portion of a protein or other molecule that is the specific target of an immune response.

EPSTEIN-BARR VIRUS (EBV). A virus in the herpes family that causes mononucleosis.

EQUATOR. Imaginary line encircling the eyeball and dividing the eye into a front and back half.

ERADICATE. To completely do away with something, eliminate it, end its existence.

ERECTILE DYSFUNCTION (ED). The consistent inability to achieve or maintain a penile erection.

ERGONOMICS. The study of the relationship between people and their working environment.

ERGOTAMINE. A drug used to prevent or treat migraine headaches.

ERUPTION. The process of a tooth breaking through the gum tissue to grow into place in the mouth.

ERYTHEMA. The medical term for redness of the skin produced by congestion of the capillaries in the skin.

ERYTHEMA MIGRANS (EM). A red skin rash that is one of the first signs of Lyme disease in about 75% of patients.

ERYTHEMA MULTIFORME. A type of hypersensitivity (allergic) reaction that occurs in response to medications, infections, or illness.

ERYTHROBLASTOPENIA. A deficiency in the cells that create red blood cells. This condition may be severe and life-threatening, but there is a transient form, seen in young children, which resolves spontaneously and does not recur.

ERYTHROBLASTOSIS FETALIS. A disorder of newborn infants marked by a high level of immature red blood cells (erythroblasts).

ERYTHROCYTE SEDIMENTATION RATE (ESR). The rate at which red blood cells settle out in a tube of unclotted blood, expressed in millimeters per hour; elevated sedimentation rates indicate the presence of inflammation.

ERYTHROCYTE. The name for red blood cells or red blood corpuscles. These components of the blood are responsible for carrying oxygen to tissues and removing carbon dioxide from tissues.

ERYTHROCYTOSIS. Increased production of red blood cells.

ERYTHRODERMA. An abnormal reddening of the entire skin surface.

ERYTHROGENIC TOXIN. A toxin or agent produced by the scarlet fever-causing bacteria that causes the skin to turn red.

ERYTHROMYCIN. An antibiotic that can be used instead of penicillin.

ERYTHROPOIESIS. The process through which new red blood cells are created; it begins in the bone marrow.

ERYTHROPOIETIC. Referring to the creation of new red blood cells.

ERYTHROPOIETIN. A hormone produced by the kidneys that stimulates the production of red blood cells by bone marrow.

ESCHAR. A hardened black crust of dead tissue that may form over a wound.

ESCHERICHIA COLI. A type of enterobacterium that is responsible for most cases of severe bacterial diarrhea in the United States.

ESCITALOPRAM OXALATE. An SSRI that is very similar to citalopram hydrobromide.

ESOPHAGEAL ATRESIA. Blockage or closure of the esophagus, the tube leading from the mouth to the stomach.

ESOPHAGEAL MANOMETRY. A test in which a thin tube is passed into the esophagus to measure the degree of pressure exerted by the muscles of the esophageal wall.

ESOPHAGEAL SPHINCTER. A circular band of muscle that closes the last few centimeters of the esophagus and prevents the backward flow of stomach contents.

ESOPHAGEAL VARIX. An enlarged vein of the esophagus. (Plural: esophageal varices.)

ESOPHAGITIS. Inflammation of the esophagus.

ESOPHAGOGASTRODUODENOSCOPY (EGD). A test that involves visually examining the lining of the esophagus, stomach, and upper duodenum with a flexible fiber-optic endoscope.

ESOPHAGOMYOTOMY. A surgical incision through the muscular tissue of the esophagus.

ESOPHAGOSCOPY (ALSO ESOPHAGOENDOSCOPY). Examination of the inside of the esophagus using a flexible tube that transmits video images.

ESOPHAGUS. The muscular tube that leads from the back of the throat to the entrance of the stomach.

ESSENCE. The constituent of a plant that determines its characteristics.

ESSENTIAL FATTY ACIDS. Sources of fat in the diet, including omega-3 and omega-6 fatty acids.

ESSENTIAL OIL. A volatile oil extracted from the leaves, fruit, flowers, roots, or other components of a plant and used in aromatherapy, perfumes, and foods and beverages.

ESSENTIAL TREMOR. An uncontrollable (involuntary) shaking of the hands, head, and face. Also called familial tremor because it is sometimes inherited, it can begin in the teens or in middle age. The exact cause is not known.

ESTRODIOL. The most physiologically active form of estrogen.

ESTROGEN REPLACEMENT THERAPY (ERT). A treatment in which estrogen is used therapeutically during menopause to alleviate certain symptoms such as hot flashes. ERT has also been shown to reduce the risk of osteoporosis and heart disease in women.

ESTROGEN. A female hormone produced by the ovaries that stimulates the growth of the lining of the uterus.

ETHANOL. The chemical name for beverage alcohol. It is also sometimes called ethyl alcohol or grain alcohol to distinguish it from isopropyl or rubbing alcohol.

ETHINYL ESTRADIOL. A semi-synthetic derivative of estradiol—an estrogen or female sex hormone—used in birth control pills and combined ECPs.

EUPHORIA. An exaggerated state of psychological and physical well-being.

EUSTACIAN TUBE. A tube connecting the middle ear with the back of the nose, allowing air pressure to equalize within the ear whenever it opens, such as with yawning.

EUSTRESS. A term that is sometimes used to refer to positive stress.

EUTHANASIA. The act of putting individuals or animals to death painlessly or allowing them to die by withholding medical services, usually because of an incurable disease; also called mercy killing.

EUTHYROID. Having the right amount of thyroxin stimulation.

EVENT RECORDER. A small machine, worn by a patient usually for several days or weeks, that is activated by the patient to record his or her EKG when a symptom is detected.

EVIDENCE-BASED MEDICINE. Recommendations that are based on an evaluation of randomized, controlled trials; non-randomized trials; other experiments; descriptive studies; and reports of expert committees.

EVISERATED. Removal of eye contents.

EVOKED POTENTIAL. A test of nerve response that uses electrodes placed on the scalp to measure brain reaction to a stimulus such as a touch.

EVULSION. The forceful, and usually accidental, removal of a tooth from its socket in the bone.

EX UTERO INTRAPARTUM TREATMENT (EXIT). A cesarean section in which the infant is removed from the uterus but the umbilical cord is not cut until after surgery for a congenital defect that blocks an air passage.

EXANTHEM (PLURAL, EXANTHEMS OR EXANTHEMATA). A skin eruption regarded as a characteristic sign of such diseases as measles, German measles, and scarlet fever.

EXCIMER LASER. An instrument that is used to vaporize tissue with a cold, coherent beam of light with a single wavelength in the ultraviolet range.

EXCISIONAL BIOPSY. Removal of an entire lymph node; often the most suspicious-looking node is removed for testing.

EXHIBITIONISM. Obtaining sexual arousal by exposing genitals to an unsuspecting stranger.

EXOCRINE. A system of organs that produces chemicals that go through a duct (or tube) to reach other organs whose functioning they affect.

EXOPHTHALMOS. A condition in which the eyes stick out of their sockets and inhibit proper eyelid function.

EXOTOXIN. A poisonous secretion produced by bacilli which is carried in the bloodstream to other parts of the body.

EXPECTORANT. Drug used to thin mucus.

EXPLICIT MEMORY. Conscious recall of facts and events that is classified into episodic memory (involves time and place) and semantic memory (does not involve time and place).

EXSTROPHY. Being turned inside out combined with being outside the body.

EXTENDED FAMILY FIELD. A person's family of origin plus grandparents, in-laws, and other relatives.

EXTENSIVE SUPPORT. Ongoing daily support required to assist an individual in a specific adaptive area, such as daily help with preparing meals.

EXTENSOR MUSCLES. A group of muscles in the forearm that serve to lift or extend the wrist and hand. Tennis elbow results from overuse and inflammation of the tendons that attach these muscles to the outside of the elbow.

EXTERNAL RADIATION THERAPY. Radiation therapy that focuses high-energy rays from a machine on the area of the tumor.

EXTRACORPOREAL. Outside of, or unrelated to, the body.

EXTRACORPOREAL CIRCUIT (ECC). The path the hemodialysis patient's blood takes outside of the body. It typically consists of plastic tubing, a hemodialysis machine, and a dialyzer.

EXTRACTION. The surgical removal of a tooth from its socket in a bone.

EXTRACTION SITE. The empty tooth socket following removal of the tooth.

EXTRAGONADAL. Occurring outside of the gonads or outside of the reproductive organs.

EXTRAOCULAR MUSCLES. The muscles (lateral rectus, medial rectus, inferior rectus, superior rectus, superior oblique, and inferior oblique) that move the eyeball.

EXTRAOCULAR RETINOBLASTOMA. Cancer that has spread from the eye to other parts of the body.

EXTRAPYRAMIDAL SYMPTOMS (EPS). A group of side effects associated with antipsychotic medications. EPS include parkinsonism, akathisia, dystonia, and tardive dyskinesia.

EXTRINSIC PATHWAY. One of three pathways in the coagulation cascade.

EXTUBATION. Removal of a breathing tube.

EXUDATE. Cells, protein, fluid, or other material that passes through blood vessel walls and accumulates in the surrounding tissue.

F

FACE MASK. The simplest way of delivering a high level of oxygen to patients with ARDS or other low-oxygen conditions.

FACELIFT. Plastic surgery performed to remove sagging skin and wrinkles from an individual's face.

FACIOSCAPULOHUMERAL MUSCULAR DYSTROPHY (FSH). This form of muscular dystrophy, also known as Landouzy–Dejerine condition, begins in late childhood to early adulthood and affects both men and women, causing weakness in the muscles of the face, shoulders, and upper arms.

FACTITIOUS DISEASES. Conditions in which symptoms are deliberately manufactured by patients in order to gain attention and sympathy; also known as factitious disorders.

FACTOR VIII. A protein involved in blood clotting that requires von Willebrand factor for stability and long-term survival in the bloodstream.

FACTOR. Any of several substances necessary to produce a result or activity in the body. The term is used when the chemical nature of the substance is unknown. In endocrinology, when the chemical nature is known, factors are renamed hormones.

FAGET'S SIGN. The simultaneous occurrence of a high fever with a slowed heart rate.

FALLOPIAN TUBES. Part of the internal female anatomy that carries eggs from the ovaries to the uterus.

FALSE NEGATIVE. Test results showing no problem when one exists.

FAMCICLOVIR. An oral antiviral drug that blocks the replication of the varicella zoster virus.

FAMILIAL POLYPOSIS. An inherited condition in which lumps of tissue (polyps) form inside the colon. Familial polyposis may develop into cancer.

FAMILY SYSTEMS THEORY. An approach to treatment that emphasizes the interdependency of family members rather than focusing on individuals in isolation from the family. This theory underlies the most influential forms of contemporary family therapy.

FANCONI'S ANEMIA. An inherited form of aplastic anemia.

FANCONI'S SYNDROME. A kidney disorder in which glucose, amino acids, uric acid, phosphate,

and bicarbonate are passed into the urine instead of being reabsorbed into the blood.

FARMER'S LUNG. An allergic reaction to moldy hay, most often seen in farmers, that results in lung disease.

FASCIA. The sheet of connective tissue that covers the body under the skin and envelops the muscles and various organs.

FASCIA, DEEP. A fibrous layer of tissue that envelopes muscles.

FASCIA, SUPERFICIAL. A fibrous layer of tissue that lies between the deepest layer of skin and the subcutaneous fat.

FASCICULATIONS. Involuntary twitching of patient's muscles.

FAT. Molecules composed of fatty acids and glycerol; the slowest utilized source of energy, but the most energy-efficient form of food. Each gram of fat supplies about nine calories, more than twice that supplied by the same amount of protein or carbohydrate.

FAT-SOLUBLE VITAMIN. A vitamin that dissolves easily in fat or oil, but not in water. The fat-soluble vitamins are vitamins D, E, A, and K.

FATIGUE. Loss of energy; tiredness.

FATTY LIVER. An abnormal amount of fat tissue in the liver caused by alcohol abuse.

FEBRILE SEIZURE. Convulsions brought on by fever.

FECAL IMPACTION. Obstruction of the rectum by a large mass of feces (stool).

FECES. Bodily waste material that normally passes through the anus.

FELDENKRAIS METHOD. A therapy based on creating a good self image by correction and improvements of body movements.

FELTY'S SYNDROME. An autoimmune disorder in which neutropenia is associated with rheumatoid arthritis and an enlarged spleen.

FEMALE ATHLETE TRIAD. A combination of disorders frequently found in female athletes that includes disordered eating, osteoporosis, and oligo- or amenorrhea. The triad was first officially named in 1993.

FEMALE STERILIZATION. The process of permanently ending a woman's ability to conceive by tying off or cutting apart the fallopian tubes.

FEMORAL ARTERY. An artery located in the groin area that is the most frequently accessed site for arterial puncture in angiography.

FEMUR. The thighbone.

FERRITIN. A protein found in the liver, spleen, and bone marrow that stores iron.

FERTILIZATION. The joining of the sperm and the egg; conception.

FETAL. Refers to the fetus, also known in the first two months after conception as an embryo.

FETAL ALCOHOL SYNDROME. A cluster of birth defects that includes abnormal facial features and mental retardation, caused by the mother's consumption of alcoholic beverages during pregnancy.

FETAL TISSUE TRANSPLANTATION. A method of treating Parkinson's and other neurological diseases by grafting brain cells from human fetuses onto the affected area of the human brain. Human adults cannot grow new brain cells but developing fetuses can. Grafting fetal tissue stimulates the growth of new brain cells in affected adult brains.

FETISHISM. Obtaining sexual arousal using or thinking about an inanimate object or part of the body.

FETOSCOPE. A fiber-optic instrument for viewing the fetus inside the uterus.

FETUS. A baby developing in the uterus from the third month to birth.

FIBER. Also known as roughage or bulk. Insoluble fiber moves through the digestive system almost undigested and gives bulk to stools. Soluble fiber dissolves in water and helps keep stools soft.

FIBEROPTICS. In medicine, fiberoptics uses glass or plastic fibers to transmit light through a specially designed tube. The tube is inserted into organs or body cavities where it transmits a magnified image of the internal body structures.

FIBRILLATION. Rapid, uncoordinated contractions of the upper or the lower chambers of the heart.

FIBRILLIN. A protein that is an important part of the structure of the body's connective tissue. In Marfan's syndrome, the gene responsible for fibrillin has mutated, causing the body to produce a defective protein.

FIBRIN. The protein formed as the end product of the blood clotting process when fibrinogen interacts with thrombin.

FIBRIN SPLIT PRODUCTS (FSP). Pieces of the protein fibrin released from a dissolving clot.

FIBRINOGEN. A type of blood protein called a globulin that interacts with thrombin to form fibrin.

FIBRINOLYSIS. The clot dissolving portion of the coagulation process.

FIBROADENOMA. A benign breast growth made up of fibrous tissue.

FIBROBLAST. A connective-tissue cell.

FIBROID TUMOR. A noncancerous tumor formed of fibrous tissue.

FIBROIDS. Benign (noncancerous) growths that arise from the smooth muscle layer and connective tissue of the uterus. They sometimes cause secondary dysmenorrhea.

FIBROMA. A usually benign tumor consisting of fiborous tissue.

FIBROMUSCULAR DYSPLASIA. A disorder that causes unexplained narrowing of arteries and high blood pressure.

FIBROMYALGIA. A chronic disease syndrome characterized by fatigue, widespread muscular soreness, and pain at specific points on the body.

FIBROSIS. A condition characterized by the presence of scar tissue, or reticulin and collagen proliferation in tissues to the extent that it replaces normal tissues.

FIBROUS CONNECTIVE TISSUE. Dense tissue found in various parts of the body containing very few living cells.

FIFTH DISEASE. Erythema infectiosum; a common respiratory infection among children caused by parvovirus B19 that usually is not serious but can cause fetal complications.

FILARIAL. Threadlike. The word "filament" is formed from the same root word.

FILARIASIS. A tropical disease caused by worms that live in lymph channels.

FILARIFORM. Threadlike in appearance, like the infectious stage of the threadworm larva.

FILLING. Dental material that occupies the space remaining within a tooth after the decayed portion has been removed.

FILTRATE. The medical term for the water and small molecules filtered in the nephron of the kidney.

FINE NEEDLE ASPIRATION BIOPSY. A procedure using a thin needle to remove fluid and cells from a lump in the breast.

FINGER STICK. A technique for collecting a very small amount of blood from the fingertip area.

FIRST–RANK SYMPTOMS. A set of symptoms designated by Kurt Schneider in 1959 as the most important diagnostic indicators of schizophrenia. These symptoms include delusions, hallucinations, thought insertion or removal, and thought broadcasting. First–rank symptoms are sometimes referred to as Schneiderian symptoms.

FISSURE. Any cleft or groove, normal or otherwise, especially a deep fold in the anus.

FISTULA. A passageway formed by a disease or injury that drains fluid from an infected area to the outside or to other parts of the body.

FLACCID. Flabby, limp, weak.

FLACCID PARALYSIS. Paralysis characterized by limp, unresponsive muscles.

FLAGELLATE. A microorganism that uses flagella (hair-like projections) to move.

FLAGELLUM. A tail–like projection extending from the cell walls of certain bacteria. Its name is the Latin word for "whip."

FLAP. A section of tissue moved from one area of the body to another.

FLARE AND CELL. A pattern revealed by slit-lamp examination that indicates uveitis. Flare and cell resembles light filtered through smoke.

FLASHBACK. A temporary reliving of a traumatic event.

FLATULENCE. Excess gas in the digestive tract.

FLATUS. Gas or air in the digestive tract.

FLAVIVIRUS. An arbovirus that can cause potentially serious diseases, such as dengue, yellow fever, Japanese encaphilitis, and West Nile fever.

FLAVONOID. A food chemical that helps to limit oxidative damage to the body's cells, and protects against heart disease and cancer.

FLOATERS. Translucent specks that float across the visual field, due to small objects floating in the vitreous humor.

FLORA. Living inhabitants of a region or area.

FLUENCY. The ability to produce a flow of words and not get "stuck," as in stuttering.

FLUKE. A parasitic flatworm that has external suckers. Flukes are sometimes called trematodes.

FLUORESCEIN. A fluorescent chemical used to examine the cornea.

FLUORESCEIN DYE. An orange dye used to illuminate the blood vessels of the retina in fluorescein angiography.

FLUORESCENCE IN SITU HYBRIDIZATION (FISH). A technique used to detect small deletions or rearrangements in chromosomes.

FLUORESCENT ANTIBODY TEST (FA TEST). A test in which a fluorescent dye is linked to an antibody for diagnostic purposes.

FLUORIDE. A chemical compound containing fluorine that is used to treat water or applied directly to teeth to prevent decay.

FLUOROQUINOLONES. A relatively new group of antibiotics that have had good success in treating infections with many gram-negative bacteria, such as *Shigella*; they should not be used in children under 17 years of age, because of possible effect on bone or cartilage growth.

FLUOROSCOPE. A device used in some radiology procedures that provides immediate images and motion on a screen much like those seen at airport baggage security stations.

FLUOROURACIL. A cell-killing (cytotoxic) medication that can be applied in cream form to treat cancer of the penis.

FLUOXETINE. The first SSRI; marketed as Sarafem for treating PMDD.

FLUVOXAMINE. An SSRI that is used to treat obsessive-compulsive disorder as well as other conditions.

FMR-1 GENE. A gene found on the X chromosome. Its exact purpose is unknown, but it is suspected that the gene plays a role in brain development.

FOLEY CATHETER. A tube that drains urine from the bladder.

FOLIC ACID. One of the B vitamins important for healthy growth of the fetus. It is essential to the normal development of a baby's spine, brain and skull, especially during the first four weeks of pregnancy.

FOLLICLE. The small sac at the base of a hair shaft. The follicle lies below the skin surface.

FOLLICLE STIMULATING HORMONE (FSH). A female hormone that regulates ovulation and menstruation.

FOLLICULAR. Relating to one of the round cells in the ovary that contain an ovum.

FOMITE. An inanimate object that can transmit infectious organisms.

FONTANEL. One of the membranous intervals between the uncompleted angles of the parietal and neighboring bones of a fetal or young skull; so called because it exhibits a rhythmical pulsation.

FOOD IRRADIATION METHODS. A process using radiant energy to kill microorganisms in food, to extend the amount of time in which food can be sold and eaten safely.

FOOD-BORNE ILLNESS. A disease that is transmitted by eating or handling contaminated food.

FOOTLING BREECH. A position of the fetus while in the uterus where the feet of the fetus are nearest the cervix and will be the first part of the fetus to exit the uterus, with the head of the fetus being the last part to exit the uterus.

FORAMEN (PLURAL, FORAMINA). The medical term for a natural opening or passage. The foramina of the spinal column are openings between the vertebrae for the spinal nerves to branch off from the spinal cord.

FORAMEN MAGNUM. The opening at the base of the skull, through which the spinal cord and the brainstem pass.

FORCED EXPIRATORY VOLUME (FEV). The volume of air exhaled from the beginning of expiration to a set time (usually 0.5, 1, 2, and 3 seconds).

FORCED VITAL CAPACITY (FVC). The volume of air that can be exhaled forceably after a maximal inspiration.

FOREMILK. Thin watery milk found at the beginning of breast feeding.

FORENSIC. Pertaining to or used during legal proceedings.

FORESKIN. A covering fold of skin over the tip of the penis.

FOVEA. A small area of the retina responsible for acute vision.

FRACTIONATION. A laboratory test or process in which blood or another fluid is broken down into its components. Fractionation can be used to assess the proportions of the different types of cholesterol in a

blood sample. In radiation therapy, it is used to divide a dose of radiation into smaller treatment doses.

FRACTURE. A break in a bone.

FRAGILE X SYNDROME. A genetic condition related to the X chromosome that affects mental, physical, and sensory development.

FREE FLAP. A section of tissue detached from its blood supply, moved to another part of the body, and reattached by microsurgery to a new blood supply.

FREE RADICAL. An unstable molecule that causes oxidative damage by stealing electrons from surrounding molecules, thereby disrupting activity in the body's cells.

FREQUENCY. Sound, whether traveling through air or the human body, produces vibrations—molecules bouncing into each other—as the shock wave travels along. The frequency of a sound is the number of vibrations per second. Within the audible range, frequency means pitch—the higher the frequency, the higher a sound's pitch.

FRONTAL CORTEX. The part of the human brain associated with aggressiveness and impulse control. Abnormalities in the frontal cortex are associated with an increased risk of suicide.

FRONTAL LOBE. The largest, most forward-facing part of each side or hemisphere of the brain.

FROTTEURISM. Obtaining sexual arousal and gratification by rubbing one's genitals against others in public places.

FROZEN SHOULDER. A shoulder that becomes scarred and cannot move.

FRUCTOSE. A monosaccharide sugar found in many fruits.

FUCHS' DYSTROPHY. A hereditary disease of the inner layer of the cornea. Treatment requires penetrating keratoplasty. The lens of the eye may also be affected and require surgical replacement at the same time as the cornea.

FUGUE. A dissociative experience during which a person travels away from home, has amnesia for their past, and may be confused about their identity but otherwise appear normal.

FULMINANT. Occurring or flaring up suddenly and with great severity. A potentially fatal complication of amebic dysentery is an inflammation of the colon known as fulminant colitis.

FULMINATING COLITIS. A potentially fatal complication of amebic dysentery marked by sudden and severe inflammation of the intestinal lining, severe bleeding or hemorrhaging, and massive shedding of dead tissue.

FUNCTIONAL CYST. A benign cyst that forms on the ovary and resolves on its own without treatment.

FUNCTIONAL PAIN. Pain that does not have a structural or organic cause.

FUNCTIONAL RESIDUAL CAPACITY (FRC). The volume of air left in the lungs at the end of passive expiration (breathing out). It can be measured by body plethysmography.

FUNDOPLICATION. A surgical procedure that increases pressure on the LES by stretching and wrapping the upper part of the stomach around the sphincter.

FUNDUS. The inside of an organ. In the eye, refers to the back area that can be seen with the ophthalmoscope.

FUNGI. A kingdom of saprophytic and parasitic spore–producing organisms that include mushrooms and yeast.

FUNGUS. A member of a group of simple organisms that are related to yeast and molds.

FUNNEL BREAST. A condition where there is a hollow depression in the lower part of the chest.

FURUNCULOSIS. A condition in which the patient suffers from recurrent episodes of boils.

G

GADOLINIUM. A very rare metallic element useful for its sensitivity to electromagnetic resonance, among other things. Traces of it can be injected into the body to enhance the MRI pictures.

GAG REFLEX. A normal reflex consisting of elevation of the palate, retraction of the tongue, and contraction of the throat muscles.

GALACTORRHEA. Excessive or spontaneous flow of milk.

GALACTOSE. One of two simple sugars, the other being glucose, that make up the protein lactose found in milk. Galactose can be toxic in high levels.

GALACTOSEMIA. A rare genetic disorder where an infant cannot metabolize the sugar in breast milk, and therefore cannot breastfeed

GALLBLADDER. A small, pear-shaped organ in the upper right-hand corner of the abdomen. It is

connected by a series of ducts (tube-like channels) to the liver, pancreas, and duodenum (first part of the small intestine). The gallbladder receives bile from the liver and concentrates and stores it. After a meal, bile is squeezed out of the gallbladder into the intestine, where it aids in digestion of food.

GALLIUM. A form of radionuclide that is used to help locate tumors and inflammation (specifically referred to as GA67 citrate).

GALLOP RHYTHM. An abnormal heart rhythm in which the doctor can hear three (sometimes four) sounds instead of the usual two, resembling the rhythm of a horse's gallop.

GALLSTONE ILEUS. Obstruction of the large intestine caused by a gallstone that has blocked the intestinal opening.

GAMETE. An egg (ovum) from the female or a mature sperm from the male.

GAMETE INTRAFALLOPIAN TUBE TRANSFER (GIFT). A reproductive procedure in which eggs are taken from a woman's ovaries, mixed with sperm, and then deposited into the woman's fallopian tube.

GAMMA CAMERA. A device inside the SPECT machine that forms images of the gamma rays emitted by the radionuclides used in tracers in nuclear medicine.

GAMMA GLOBULIN. One of a group of proteins found in the blood that is involved in helping the body fight infections.

GAMMA KNIFE. High-dose radiation treatment for intracranial tumors.

GAMMA RAYS. Short wavelength, high energy electromagnetic radiation emitted by radioactive substances.

GANGLION. A mass of nerve tissue outside of the central nervous system.

GANGLIONEUROMA. A ganglioneuroma is a tumor composed of mature nerve cells.

GANGLIOSIDE. A fatty (lipid) substance found within the brain and nerve cells.

GANGRENE. Death of tissue due to loss of blood supply followed by bacterial invasion and putrefaction.

GANSER'S SYNDROME. An unusual factitious disorder characterized by dissociative symptoms and absurd answers to direct questions.

GANTRY. A name for the couch or table used in a CT scan. The patient lies on the gantry while it slides into the x-ray scanner portion.

GAS EMBOLISM. The presence of gas bubbles in the bloodstream that obstruct circulation. Also called air embolism.

GAS EXCHANGE. The process by which oxygen is extracted from inhaled air into the bloodstream, and, at the same time, carbon dioxide is eliminated from the blood and exhaled.

GASTRIC. Relating to the stomach.

GASTRIC LAVAGE. Also called a stomach pump. For this procedure, a flexible tube is inserted through the nose, down the throat, and into the stomach and the contents of the stomach are suctioned out. The inside of the stomach is rinsed with a saline (salt water) solution.

GASTRIC (OR PEPTIC) ULCER. An ulcer (sore) of the stomach, duodenum or other part of the gastrointestinal system. Though the causes are not fully understood, they include excessive secretion of gastric acid, stress, heredity, and the use of certain drugs, especially acetylsalicylic acid and nonsteroidal anti-inflammatory-drugs.

GASTRIN. A hormone secreted in the stomach that is involved in the production of gastric acid. Overproduction of gastric acid contributes to peptic ulcer formation.

GASTRINOMA. Tumor that arises from the gastrin-producing cells in the pancreas.

GASTROENTERITIS. An inflammation of the lining of the stomach and intestines, usually caused by a viral or bacterial infection.

GASTROENTEROLOGIST. A doctor who specializes in diagnosing and treating diseases of the digestive system.

GASTROESOPHAGEAL REFLUX DISEASE (GERD). A condition in which gastric juice from the stomach backs up into the bottom of the esophagus and causes irritation, inflammation, or erosion of the cells lining the esophagus.

GASTROINTESTINAL. Pertaining to the stomach and intestines.

GASTROINTESTINAL TRACT. A group of organs and related structures that includes the esophagus, stomach, liver, gallbladder, pancreas, small intestine, large intestine, rectum, and anus.

GASTROJEJUNOSTOMY. A surgical procedure in which the stomach is surgically connected to the jejunum (middle portion of the small intestine).

GASTROPLASTY. A surgical procedure used to reduce digestive capacity by shortening the small intestine or shrinking the side of the stomach.

GASTROSCOPY. Looking into the stomach with a flexible viewing instrument called a gastroscope.

GASTROSTOMY. Surgical creation of an artificial opening into the stomach through the abdominal wall to allow tube feeding.

GASTROSTOMY TUBE. Stomach tube for feeding.

GAUCHER'S DISEASE. A rare genetic disease caused by a deficiency of enzymes needed for the processing of fatty acids.

GELASTIC SEIZURES. Seizures manifesting with brief involuntary laughter.

GENDER IDENTITY DISORDER (GID). A condition in which a person strongly identifies with the opposite gender and feels uncomfortable with his or her biological sex. It occurs more often in males than in females.

GENDER REASSIGNMENT SURGERY. The surgical alteration and reconstruction of a person's sex organs to resemble those of the other sex as closely as possible. It is sometimes called gender reassignment surgery.

GENE. The basic unit of genetic material carried in a particular place on a chromosome. Genes are passed on from parents to child during conception and determine how traits such as blood type are inherited and expressed.

GENE THERAPY. A method of treating a disorder by replacing damaged or abnormal genes with normal ones.

GENERAL ANESTHESIA. Deep sleep induced by a combination of medicines that allows surgery to be performed.

GENERAL PARESIS. An advanced form of neurosyphilis affecting personality and control of movement and possibly causing convulsions or partial paralysis.

GENERAL SURGEON. A physician who has special training and expertise in performing a variety of operations.

GENETIC CLUSTER. A group of viral strains with very similar, yet distinct, nucleic acid sequences.

GENETIC DISEASE. A disease that is (partly or completely) the result of the abnormal function or expression of a gene; the inheritance and expression of a genetic mutation.

GENIOPLASTY. An operation performed to reshape the chin. Genioplasties are often done to treat OSA because the procedure changes the structure of the patient's upper airway.

GENITAL. Sexual organ.

GENITAL HERPES. A sexually-transmitted disease caused by the herpes simplex virus.

GENOGRAM. A family tree diagram that represents the names, birth order, sex, and relationships of the members of a family. Therapists use genograms to detect recurrent patterns in the family history and to help the members understand their problem(s).

GENOGROUP. Related viruses within a genus; may be further subdivided into genetic clusters.

GENOME. The genetic makeup of a cell, composed of DNA.

GENOTYPE. The genetic makeup of a cell or organism.

GENU VALGUM. Deformity in which the legs are curved inward so that the knees are close together, nearly or actually knocking as a person walks with ankles widely apart of each other.

GENUINE URINARY STRESS INCONTINENCE (USI). Stress incontinence due to hypermobility of the urethra.

GEOPHAGIA. The compulsive eating of earthy substances, including sand, soil, and clay.

GERM. A disease-causing microorganism.

GERM CELL. One of the cells that ordinarily develops into eggs or sperm (also sperm and eggs).

GERMINOMA. A tumor of germ cells (ovum and sperm cells that participate in production of the developing embryo).

GESTALT THERAPY. A humanistic therapy technique that focuses on gaining an awareness of emotions and behaviors in the present rather than in the past.

GESTATION. The period from conception to birth, during which the developing fetus is carried in the uterus.

GESTATIONAL AGE. The estimated age of a fetus expressed in weeks, calculated from the first day of the last normal menstrual period.

GESTATIONAL TROPHOBLASTIC DISEASE. A rare, aggressive, malignant, often metastatic (spreading to other organs) cancer in women of childbearing age in

which cancer cells grow in the tissues that are formed in the uterus after conception.

GHRELIN. A peptide hormone secreted primarily by the stomach that has been implicated in the control of food intake and fat storage.

GIANT CELL ARTERITIS. Also called temporal arteritis. A condition which causes the inflammation of temporal arteries. It can cause blindness when the inflammation effects the ophthalmic artery.

GIARDIA LAMBLIA. A type of protozoa with a whip-like tail that infects the human intestinal tract, causing giardiasis. The protozoa will not spread to other parts of the body.

GIARDIASIS. A condition in which the intestines are infected with *Giardia lamblia*, a type of protozoan.

GIGANTISM. Excessive growth, especially in height, resulting from overproduction during childhood or adolescence of growth hormone by a pituitary tumor. Untreated, the tumor eventually destroys the pituitary gland, resulting in death during early adulthood. If the tumor develops after growth has stopped, the result is acromegaly, not gigantism.

GILBERT'S SYNDROME. A mild hereditary form of jaundice.

GILLBERG'S CRITERIA. A six–item checklist for Asperger syndrome developed by Christopher Gillberg, a Swedish researcher. It is widely used as a diagnostic tool.

GINGIVITIS. Inflammation of the gums, seen as painless bleeding during brushing and flossing.

GINKGO. An herb from *Ginkgo biloba*, a shade tree native to China with fan-shaped leaves and fleshy seeds with edible kernels.

GLAND. A collection of cells that releases certain chemicals, or hormones, that are important to the functioning of other organs or body systems.

GLANS. The head of the penis.

GLAUCOMA. A condition in which pressure in the eye is abnormally high, damaging the optic nerve. If not treated, glaucoma may lead to blindness.

GLEASON GRADING SYSTEM. A method of predicting the tendency of a tumor in the prostate to metastasize based on how similar the tumor is to normal prostate tissue.

GLOBAL APHASIA. A condition characterized by either partial or total loss of the ability to communicate verbally or using written words as a result of widespread injury to the language areas of the brain. This condition may be caused by a stroke, head injury, brain tumor, or infection.

GLOBIN. Protein component of hemoglobin. Normal adult hemoglobin has a pair each of alpha-globin and beta-globin molecules that each contain a heme group.

GLOBULINS. A group of proteins in blood plasma whose levels can be measured by electrophoresis in order to diagnose or monitor a variety of serious illnesses.

GLOMERULAR KIDNEY DISEASE. Disease of the kidney that affects the glomeruli, the part of the kidney that filters certain substances out of the blood.

GLOMERULI (SINGULAR, GLOMERULUS). Groups of tiny blood vessels with very thin walls that function as filters in the kidney.

GLOMERULONEPHRITIS. An inflammation of the filtering units of the kidney (glomeruli). The condition impairs the kidney's ability to filter waste products, salt, and water from the bloodstream, leading to serious complications such as renal failure.

GLOSSOPHARYNGEAL NEURALGIA. Sharp recurrent pain deep in the throat that extends to the area around the tonsils and possibly the ear. It is triggered by swallowing or chewing.

GLOTTIS. The opening between the vocal cords at the upper part of the larynx.

GLUCOCEREBROSIDE. A cerebroside that contains glucose in the molecule.

GLUCOCORTICOID THERAPY. Treatment using corticoids that are anti-inflammatory and immunosuppressive.

GLUCOCORTICOIDS. A class of steroid hormones synthesized by the adrenal cortex that are involved in fat, protein, and carbohydrate metabolism and that have anti-inflammatory and immunosuppressive actions; also known as glucocorticosteroids.

GLUCOSE. A simple sugar produced when carbohydrates are broken down in the small intestine. It is the primary source of energy for the body.

GLUCOSE-6-PHOSPHATE DEHYDROGENASE (G6PD) DEFICIENCY. An inherited disorder in which the body lacks an enzyme that normally protects red blood cells from toxic chemicals. When people with this condition take certain drugs, or sometimes when they have a fever or an infection, their red blood cells break down, causing anemia.

GLUTATHIONE. A molecule that acts as a co-enzyme in cellular oxidation-reduction reactions.

GLUTEN. A protein found in wheat, rye, barley, and oats.

GLUTEN ENTEROPATHY. A hereditary malabsorption disorder caused by sensitivity to gluten, a protein found in wheat, rye, barley, and oats. Also called nontropical sprue or Celiac disease.

GLYCEMIC INDEX (GI). A ranking from 1–100 that measures how much carbohydrate-containing foods raise blood sugar levels within two hours after being eaten. Foods with a glycemic index of 50 or lower are considered "good" because they are digested at a slower rate.

GLYCOGEN. A macromolecule composed mainly of glucose that serves as the storage form of glucose that is not immediately needed by the body.

GLYCOGENOLYSIS. The process of tearing-down a glycogen molecule to free up glucose.

GLYCOGENOSIS. An alternate term for glycogen storage disease. The plural form is glycogenoses.

GLYCOLYSIS. The pathway in which a cell breaks down glucose into energy.

GLYCOSYLATED HEMOGLOBIN. A test that measures the amount of hemoglobin bound to glucose. It is a measure of how much glucose has been in the blood during the past two to four months.

GNRH ANTAGONISTS. A group of medications that affect the reproductive hormones. These medications are used to treat fibroids, endometriosis, and infertility.

GOECKERMAN REGIMEN. UVB light therapy combined with topical coal-tar preparations.

GOITER. An abnormal enlargement of the thryroid gland.

GONADOTROPINS. Protein hormones secreted by the pituitary gland that affect and stimulate the ovaries or testes; used in treating infertility.

GONADS. Glands that make sex hormones and reproductive cells—testes in the male, ovaries in the female.

GONIOMETER. An instrument for measuring angles of a joint.

GONIOSCOPE. An instrument used to inspect the eye. It consists of a magnifier and a lens equipped with mirrors and is placed on the patient's cornea.

GONOCOCCUS (PLURAL, GONOCOCCI). The bacterium *Neisseria gonorrheae* that causes gonorrhea, a sexually transmitted infection of the genitals and urinary tract. Gonococci may occasionally affect the eye, causing blindness if not treated.

GONORRHEA. A sexually transmitted disease that affects the genital mucous membranes of men and women.

GONZALEZ REGIMEN. An alternative therapy for pancreatic cancer that includes a special diet, nutritional supplements, pancreatic enzymes, and coffee enemas.

GOUT. A type of arthritis in which uric acid, a waste product that normally passes out of the body in urine, collects in the joints and the kidneys, resulting in swollen, painful joints and possibly kidney stones.

GRAFT. A transplanted organ or other tissue.

GRAFT VERSUS HOST DISEASE. A life-threatening complication of bone marrow transplants in which the donated marrow causes an immune reaction against the recipient's body.

GRAINS. Flecks of hardened material such as bacteria or fungi spores.

GRAM STAIN. A staining procedure used to visualize and classify bacteria. The Gram stain procedure allows the identification of purple (Gram positive) organisms and red (Gram negative) organisms.

GRANULATION TISSUE. A kind of tissue formed during wound healing, with a rough or irregular surface and a rich supply of blood capillaries.

GRANULE. A small grain or pellet. Medicines that come in granule form usually are mixed with liquids or sprinkled on food before they are taken.

GRANULOCYTE. Any of several types of white blood cells that have granules in their cell substance. Neutrophils are the most common type of granulocyte.

GRANULOCYTE/MACROPHAGE COLONY STIMULATING FACTOR (GM–CSF). Also known as sargramostim, a substance produced by cells of the immune system that stimulates an attack upon foreign cells. Used to treat prostate cancers as a genetically engineered component of a vaccine that stimulates the body to attack prostate tissue.

GRANULOCYTOPENIA. A condition characterized by a deficiency of white blood cells.

GRANULOMA. A nodule or mass of chronically inflamed tissue.

GRANULOMATOUS. Resembling a tumor made of granular material.

GRANULOMATOUS DISEASE. Characterized by growth of tiny blood vessels and connective tissue.

GRANULOMATOUS MYOCARDITIS. Also called giant cell myocarditis, this noninfectious inflammation of the heart causes large areas of tissue death in the heart muscle, ventricular enlargement, and clots inside the heart chambers.

GRAVEL. The debris which is formed from a fragmented kidney stone.

GRAVES' DISEASE. An autoimmune disorder of the thyroid gland, in which the gland swells to twice its normal size and secretes too much thyroid hormone.

GRAY MATTER. The portion of the brain that contains neurons, as opposed to white matter, which contains nerve tracts.

GROIN. The region of the body that lies between the abdomen and the thighs.

GROUP A STREPTOCOCCUS. A sphere–shaped bacterium that grows in long chains and causes strep throat as well as scarlet fever and some forms of tonsillitis.

GROUP B STREPTOCOCCAL (GBS) DISEASE. A common bacterial infection that is potentially life-threatening if transmitted to a fetus during early pregnancy or birth.

GROUP THERAPY. Group interaction designed to provide support, correction through feedback, constructive criticism, and a forum for consultation and reference.

GROWTH FACTOR. A naturally occuring compound in the body that promotes cellular growth and survival.

GROWTH HORMONE. A hormone that eventually stimulates growth; also called somatotropin.

GROWTH PLATE. The place in long bones where growth occurs during childhood.

GUAIAC. A compound derived from the wood resin of guaiacum trees. Guaiac reacts with blood in the stool to produce a blue-colored reaction when peroxide is added to the sample.

GUIDE WIRE. A wire that is inserted into an artery to guide a catheter to a certain location in the body.

GUIDED IMAGERY. The use of relaxation and mental visualization to improve mood and/or physical well-being.

GUILLAIN-BARRÉ SYNDROME. A disorder in which the body's immune system attacks part of the peripheral nervous system, destroying the myelin sheath that surrounds the nerves. The syndrome usually occurs after a respiratory infection and results in progressive but reversible paralysis or weakness of multiple muscles, starting in the lower extremities and often ascending to the muscles involved in respiration.

GUMMA. A rubbery swelling or tumor that heals slowly and leaves a scar and is a symptom of tertiary syphilis.

GUTTA PERCHA. An inert, latex-like substance used for filling root canals.

GYNECOLOGIST. A physician with specialized training in diseases and conditions of the female reproductive system.

GYNECOMASTIA. Excessive growth of breast tissue in males.

H

H1N1 (SWINE FLU). A virus that was originally found in pigs, symptoms of H1N1 influenza include fever, cough, chills, fatigue, headache, and body aches.

H2 BLOCKERS. Also known as H_2 antagonists, a type of drug that relieves indigestion by reducing the production of stomach acid.

HAIR CELLS. Sensory receptors in the inner ear that transform sound vibrations into messages that travel to the brain.

HAIR FOLLICLE. A tube-like indentation in the skin from which a single hair grows.

HAIRBULB. The root of a strand of hair from which the color develops.

HALF-LIFE. The time required for half of the atoms in a radioactive substance to disintegrate.

HALITOSIS. The medical term for bad breath.

HALLUCINATION. A false or distorted sensory experience that appears to be real to the person experiencing it.

HALLUCINOGEN. A drug that distorts sensory perceptions and disturbs emotion, judgment, and memory.

HALLUCINOGEN PERSISTING PERCEPTION DISORDER (HPPD). The recurrence of LSD effects after the drug experience has ended.

HANTAVIRUS. A group of arboviruses that cause hemorrhagic fever (characterized by sudden onset, fever, aching and bleeding in the internal organs).

HAPTOGLOBIN. A protein in blood plasma that binds hemoglobin.

HARVESTING. The process of removing tissues or organs from a donor and preserving them for transplantation.

HASHIMOTO'S DISEASE. An autoimmune disorder that is the most common cause of primary hypothyroidism. It was the first disease to be recognized as an autoimmune disorder. It is named for a Japanese doctor, Hakaru Hashimoto, who first described it in 1912.

HATHA YOGA. Form of yoga using postures, breathing methods and meditation.

HDL CHOLESTEROL. High-density lipoprotein cholesterol; a component of cholesterol that helps protect against heart disease. HDL is nicknamed "good" cholesterol.

HEART ATTACK. A cardiac emergency that occurs when a clot blocks blood flow in one or more of the heart's arteries. Oxygen supply to the heart muscle is cut off, resulting in the death of heart tissue in the affected area.

HEART BLOCK. A problem with electrical conduction in the heart muscle that may lead to irregular heart beat and require a pacemaker for treatment.

HEART CATHETERIZATION. A heart catheterization is used to view the heart's chamber and valves. A tube (catheter) is inserted into an artery, usually in the groin. A dye is then put into the artery through the tube. The dye makes its way to the heart to create an image of the heart on x-ray film. The image is photographed and stored for further examination.

HEART FAILURE. A term used when the heart is unable to pump enough blood to supply the needs of the body.

HEART MURMUR. Sound during the heartbeat caused by a heart valve that does not close properly.

HEART VALVES. Valves that regulate blood flow into and out of the heart chambers.

HEARTBURN. A burning sensation in the chest that can extend to the neck, throat, and face, caused by the movement of stomach acid flowing backwards (refluxing) into the esophagus.

HEAT STROKE. A severe condition caused by prolonged exposure to high heat. Heat stroke impedes the body's ability to cool itself and can lead to collapse and coma.

HEAVY METAL. One of 23 chemical elements that has a specific gravity (a measure of density) at least five times that of water.

HEIMLICH MANEUVER. The application of sudden upward pressure on the upper abdomen to force an obstructing object from the trachea of a choking victim.

HELICOBACTER PYLORI. A gram-negative rod-shaped bacterium that lives in the tissues of the stomach and causes inflammation of the stomach lining.

HELMINTHS. Parasitic worms, such as tapeworms or liver flukes, that can live in the human body.

HEMAGGLUTINATION. The clumping or clustering of red blood cells caused by certain viruses, antibodies, or other substances.

HEMARTHROSIS. A condition of blood within a joint.

HEMATIN. A drug administered intravenously to halt an acute porphyria attack. It causes heme biosynthesis to decrease, preventing the further accumulation of heme precursors.

HEMATOCRIT. The proportion of whole blood in the body, by volume, that is composed of red blood cells.

HEMATOCRIT (HCT) LEVEL. A measure of red blood cells.

HEMATOLOGIST. A physician who specializes in diseases of the blood and blood-forming organs.

HEMATOLOGY. The medical specialty that deals with the blood and the organs that form blood.

HEMATOMA. An accumulation of blood, often clotted, in a body tissue or organ, usually caused by a break or tear in a blood vessel.

HEMATOPOIETIC CELLS. Those cells that are lodged within the bone marrow and are responsible for producing the cells that circulate in the blood (red blood cells, white blood cells, and platelets).

HEMATOPOIETIC STEM CELL. A cell that can develop into any type of specialized blood cell.

HEMATOPOIETIC SYSTEM. The system in the body responsible for the production of blood cells.

HEMATOPORPHYRIN. A dark reddish-purple pigment found in blood. A purified form of hematoporphyrin is used to make porfimer sodium.

HEMATURIA. Blood in the urine.

HEME. The iron-containing molecule in hemoglobin that serves as the site for oxygen binding.

HEMIPLEGIA. Paralysis of one side of the body.

HEMISPHERE. One of the two halves or sides—the left and the right—of the brain.

HEMIVERTEBRA. Condition in which one side of a vertebra fails to form normally before birth.

HEMOCHROMATOSIS. A disorder of iron metabolism characterized by excessive absorption of iron from food.

HEMOCYTOMETER. An instrument used to count platelets or other blood cells.

HEMODIALYSIS. The removal of waste products from the blood stream in patients with kidney failure. Blood is removed from a vein, passed through a dialysis machine, and then put back into a vein.

HEMODILUTION. A technique in which the fluid content of the blood is increased without increasing the number of red blood cells.

HEMOGLOBIN. A protein-iron compound in red blood cells that functions primarily in carrying oxygen from the lungs to the tissues of the body.

HEMOGLOBIN A. Normal adult hemoglobin that contains four heme molecules, two alpha-globin molecules, and two beta-globin molecules.

HEMOGLOBIN C DISEASE. A disease of abnormal hemoglobin, occurring in 2–3% of African Americans. Only those who have two genes for the disease develop anemia, which varies in severity. Symptoms include episodes of abdominal and joint pain, an enlarged spleen and mild jaundice.

HEMOGLOBIN ELECTROPHORESIS. A laboratory test that separates molecules based on their size, shape, or electrical charge.

HEMOGLOBIN H DISEASE. A thalassemia-like syndrome causing moderate anemia and red blood cell abnormalities.

HEMOLYSIS. The destruction or breakdown of red blood cells, resulting in the release of hemoglobin.

HEMOLYTIC. Able to break down or dissolve red blood cells.

HEMOLYTIC ANEMIA. A type of anemia marked by the premature breakdown of red blood cells.

HEMOLYTIC BACTERIA. Bacteria that are able to burst red blood cells.

HEMOLYTIC-UREMIC SYNDROME (HUS). A potentially fatal complication of *E. coli* infections characterized by kidney failure and destruction of red blood cells.

HEMOPHILIA. An inherited bleeding disorder caused by a deficiency of factor VIII, one of a series of blood proteins essential for blood clotting.

HEMOPTYSIS. The coughing up of large amounts of blood or of blood-containing sputum.

HEMORRHAGE. Abnormal and excessive bleeding.

HEMORRHAGIC. A condition resulting in massive, difficult-to-control bleeding.

HEMORRHOID. An area around the anus comprised of enlarged veins and swollen tissue, causing itching and pain.

HEMOSIDEROSIS. An overload of iron in the body resulting from repeated blood transfusions. Hemosiderosis occurs most often in patients with thalassemia.

HEMOTHORAX. Blood in the pleural cavity.

HENNA. Mehndi; a reddish-brown dye from the leaves of the henna plant; used for hair dye and temporary tattoos.

HEPARIN. A blood component that controls the amount of clotting. It can be used as a drug to reduce blood clot formation.

HEPARIN CHALLENGE TEST. A medical test to evaluate how readily the blood clots.

HEPATIC. Referring to the liver.

HEPATIC ARTERY. The blood vessel supplying arterial blood to the liver.

HEPATITIS. Inflammation of the liver caused by a virus, chemical, or drug.

HEPATITIS B. A disease that causes inflammation of the liver and serious liver damage.

HEPATOBILIARY SCAN. Another term for a gallbladder nuclear medicine scan.

HEPATOCELLULAR. Of or pertaining to liver cells.

HEPATOCYTE. A liver cell.

HEPATOMEGALY. General swelling of the liver.

HEPATOTOXIN. A substance that is toxic to the liver.

HEREDITARY. Something that is inherited or passed down from parents to offspring. In biology and medicine, the word pertains to inherited genetic characteristics.

HEREDITARY ANGIOEDEMA. A complement deficiency characterized by lymphatic vessel blockages that cause temporary swelling (edema) of areas of the skin, mucous membranes, and, sometimes, internal organs.

HEREDITARY ATAXIA. One of a group of hereditary degenerative diseases of the spinal cord or cerebellum. These diseases cause tremor, spasm, and wasting of muscle.

HEREDITARY SPHEROCYTOSIS (HS). A blood disorder in which the red blood cells are relatively fragile and are damaged or destroyed when they pass through the spleen. Splenectomy is the only treatment for HS.

HERMANSKY-PUDLAK SYNDROME (HPS). A rare type of albinism characterized by a problem with blood clotting and a buildup of waxy material in lungs and intestines.

HERNIA. A rupture in the wall of a body cavity, through which an organ may protrude.

HERNIATED DISK. A protrusion in a disk located in the spinal column.

HERNIORRHAPHY. Surgical repair of a hernia.

HERPES SIMPLEX VIRUS (HSV). A virus that causes sores on or in the mouth (cold sores, HSV type 1) or on the genitals (genital herpes, HSV type 2).

HERPES VIRUSES. A family of viruses including herpes simplex types 1 and 2, and herpes zoster (also called varicella zoster). Herpes viruses cause several infections, all characterized by blisters and ulcers, including chicken pox, shingles, genital herpes, and cold sores or fever blisters.

HERPES ZOSTER VIRUS. Acute inflammatory virus that attacks the nerve cells on the root of each spinal nerve with skin eruptions along a sensory nerve ending.

HETEROZYGOTE. An individual who has one gene in a pair that has a mutation while the other gene in the pair is unaffected.

HETEROZYGOUS. Two different genes controlling a specified inherited trait.

HIATAL HERNIA. A condition where part of the stomach protrudes through the diaphragm into the chest cavity; also called hiatus hernia.

HIB DISEASE. An infection caused by *Haemophilus influenza* type b (Hib). This disease mainly affects children under the age of five. In that age group, it is the leading cause of bacterial meningitis, pneumonia, joint and bone infections, and throat inflammations.

HIGH SPOT. An area of a tooth or restoration that feels abnormal or uncomfortable because it hits its opposing tooth before other teeth meet.

HIGH-DENSITY LIPOPROTEIN (HDL). A type of lipoprotein that protects against coronary artery disease by removing cholesterol deposits from arteries or preventing their formation.

HIGH-FUNCTIONING AUTISM (HFA). A subcategory of autistic disorder consisting of children diagnosed with IQs of 70 or higher.

HIGHLY ACTIVE ANTIRETROVIRAL THERAPY (HAART). An individualized combination of three or more antiretroviral drugs used to treat patients with HIV infection. It is sometimes called a drug cocktail.

HIGH-RISK HPV TYPE. A member of the HPV family of viruses that is associated with the development of cervical cancer and precancerous growths.

HIPPOCAMPUS. A part of the brain's limbic system that is involved in memory formation and learning.

HIRSCHSPRUNG DISEASE. Hirschsprung disease is a congenital abnormality (birth defect) of the bowel in which there is absence of the ganglia (nerves) in the wall of the bowel.

HIRSUTISM. Excessive hair growth on the face and body.

HISTAMINE. A chemical found naturally in the body that produces inflammation and increases blood flow; the uncomfortable symptoms of an allergy attack or an allergic reaction are generally caused by the release of histamine.

HISTOCOMPATIBILITY. The relationship between tissues that characterizes how well a patient and donor are matched in a transplant or graft.

HISTOCOMPATIBILITY ANTIGENS. Histocompatibility determinants; proteins scattered throughout body tissues that are unique for almost every individual.

HISTOLOGY. The study of the structure, composition, and function of tissues of organs.

HISTOPATHOLOGY. The study of diseased tissues at a minute (microscopic) level.

HISTRIONIC. A behavior characterized by an excitable nature and the constant desire for stimulation.

HIVES. A raised, itchy area of skin that is usually a sign of an allergic reaction.

HLA-B27. An antigen or protein marker on cells that may indicate ankylosing spondylitis.

HODGKIN DISEASE. Cancer of the lymphatic system, characterized by lymph node enlargement.

HOLISTIC. In medicine, a practice that focuses on treating the patient as a whole (rather than just treating the disease); addresses the physical, social, emotional, and spiritual needs of a patient.

HOLTER MONITOR. A portable device used to record heart rhythms over a period of at least 24 hours.

HOME MODIFICATION. The altering of the physical environment of the home to remove hazards and provide a more functional environment; examples include the installation of grab bars and no-slip foot mats in the bathroom to prevent falls.

HOME PARENTERAL NUTRITION (HPN). Long-term parenteral nutrition, given through a central venous catheter and administered in the patient's home.

HOMEOPATHY. The use of diluted remedies that would otherwise produce symptoms similar to those they are curing. They are prescribed according to the axiom that "like cures like."

HOMEOSTASIS. The regulation of body processes to maintain an internal balance.

HOMOCYSTEINE. An amino acid normally found in small amounts in the blood.

HOMOZYGOTE. An individual who has both genes in a pair with the same mutation.

HOMOZYGOUS. A condition in which both genes in a pair have the same mutation.

HOOKWORM. Parasitic intestinal infestation caused by any of several parasitic nematode worms of the family Ancylostomatidae. These worms have strong buccal hooks that attach to the host's intestinal lining.

HORMONE. A chemical messenger produced by the body that is involved in regulating specific bodily functions such as growth, development, reproduction, metabolism, and mood.

HORMONE REPLACEMENT THERAPY (HRT). Short-term replacement of the hormones (estrogen and progesterone) that a woman's body no longer produces after menopause; may lower the risk of osteoporosis in postmenopausal women.

HORMONE THERAPY. Manipulation of hormone levels in the body for a medical purpose, such as to inhibit menstruation (contraception); in cancer treatment, focuses on inhibiting the production of certain hormones instead of using cell-killing drugs.

HOSPICE. A facility or program that provides for the physical and emotional needs of the terminally ill in a caring environment.

HOST. An organism that is infected by a virus, bacterium, or parasite.

HOT FLASH. A wave of heat that is one of the most common perimenopausal symptoms, triggered by the hypothalamus' response to estrogen withdrawal.

"HOT TUB" FOLLICULITIS. A skin infection caused by *P. aeruginosa* that often follows bathing in a hot tub or public swimming pool.

HUMAN CHORIONIC GONADOTROPIN (HCG). A hormone produced by the placenta during pregnancy.

HUMAN HERPESVIRUS 8. Also called Kaposi's sarcoma–associated herpesvirus (KSHV), this virus is thought to be a cause for Kaposi's sarcoma.

HUMAN IMMUNODEFICIENCY VIRUS (HIV). The virus that causes acquired immune deficiency syndrome (AIDS).

HUMAN LEUCKOCYTE ANTIGEN (HLA). A group of protein molecules located on bone marrow cells that can provoke an immune response. A donor's and a recipient's HLA types should match as closely as possible to prevent the recipient's immune system from attacking the donor's marrow as a foreign material that does not belong in the body.

HUMAN PAPILLOMAVIRUS (HPV). A group of viruses that cause abnormal cell growth (warts or papillomas) on the hands, feet, or genitals; some types can cause cervical cancer.

HUMAN POTENTIAL MOVEMENT. A movement in psychotherapy that began in the 1960s and emphasized maximizing the potential of each participant through such techniques as group therapy and sensitivity training.

HUMANIZATION. Fusing the constant and variable framework region of one or more human immunoglobulins with the binding region of an animal immunoglobulin, done to reduce human reaction against the fusion antibody.

HUMERUS. The bone of the upper arm.

HUMORAL. Pertaining to or derived from a body fluid. The humoral part of the immune system includes antibodies and immunoglobulins in blood serum.

HUNTINGTON'S DISEASE. A hereditary disease that typically appears in midlife, characterized by progressive dementia and loss of control over voluntary movements. It is sometimes called Huntington's chorea.

HYALINE MEMBRANE. A fibrous layer that settles in the lungs and prevents oxygen from escaping to the bloodstream, resulting in increased carbon dioxide levels.

HYDATIDIFORM MOLE. Also called a molar pregnancy. A mass of abnormal, partially developed tissues inside the uterus (womb). Moles develop during a pregnancy that begins with an abnormal fertilization. The mass may or may not be cancerous.

HYDRATION. Taking in water or fluid to replace loss of fluid.

HYDROCELE. An accumulation of fluid in the membrane that surrounds the testis.

HYDROCEPHALUS. Abnormal accumulation of cerebrospinal fluid within the skull, causing expansion of the skull and brain.

HYDROCORTISONE. A steroid hormone produced by the adrenal glands that provides resistance to stress.

HYDROGEN. The simplest, most common element known in the universe. It is composed of a single electron (negatively charged particle) circling a nucleus consisting of a single proton (positively charged particle).

HYDROGEN PEROXIDE. A colorless, unstable compound of hydrogen and oxygen (H_2O_2). An aqueous solution of hydrogen peroxide is used as an antiseptic and bleaching agent.

HYDROPS FETALIS. A condition in which a fetus or newborn baby retains fluids, causing swollen arms and legs and impaired breathing.

HYDROTHERAPY. The use of water (hot, cold, steam, or ice) to relieve discomfort and promote physical well-being; also known as water therapy.

HYDROXYAPATITE. A calcium phosphate complex that is the primary mineral component of bone.

HYDROXYUREA. A drug that has been shown to induce production of fetal hemoglobin.

HYMEN. A membrane that partially or completely covers the vaginal opening.

HYMENOLEPIASIS. Parasitic infection caused by the presence of tapeworms from the *Hymenolepis* genus, such as the dwarf tapeworm (*Hymenolepis nana*) or the rodent tapeworm (*Hymenolepis diminuta*).

HYPERALIMENTATION. A method of re-feeding anorectics by infusing liquid nutrients and electrolytes directly into central veins through a catheter.

HYPERANDROGENISM. Excessive secretion of androgens (male sex hormones).

HYPERAROUSAL. A state of increased emotional tension and anxiety, often including jitteriness and being easily startled.

HYPERBARIC CHAMBER. A sealed compartment in which patients are exposed to controlled pressures of up to three times normal atmospheric pressure.

HYPERBARIC OXYGEN THERAPY (HBOT). A form of oxygen therapy in which the patient breathes pure oxygen in a pressurized chamber. Hyperbaric treatment may be used to regulate blood gases, reduce gas bubbles, and provide higher levels of oxygen more quickly.

HYPERBARIC OXYGENATION. Administration of oxygen in a compression chamber at an ambient pressure greater than one atmosphere, in order to increase the amount of oxygen in organs and tissues.

HYPERBILIRUBINEMIA . An excess of bilirubin in the blood.

HYPERCALCEMIA. Abnormally high levels of calcium in the blood.

HYPERCHOLESTEROLEMIA. The presence of excessively high levels of cholesterol in the blood.

HYPEREMESIS. Severe vomiting during pregnancy. Hyperemesis appears to increase a woman's risk of postpartum depression.

HYPEREXTENSIBILITY. The ability to extend a joint beyond the normal range.

HYPERGLYCEMIA. Too much glucose or sugar in the blood.

HYPERHIDROSIS. Excessive sweating. Hyperhidrosis can be caused by heat, overactive thyroid glands, strong emotion, menopause, or infection.

HYPERINFECTION SYNDROME. A condition of massive infection in which threadworm larvae multiply rapidly and spread throughout the body. It is usually associated with damage to the immune system, the use of steroid medications, or malnutrition.

HYPERINSULINEMIA. High blood insulin levels.

HYPERKALEMIA. An abnormally high level of potassium in the blood.

HYPERKETONEMIA. Condition characterized by an overproduction of ketones by the body.

HYPERLACTATION. Another term for galactorrhea.

HYPERLIPIDEMIA. Abnormally high levels of lipids in the blood.

HYPERMAGNESEMIA. An abnormally high concentration of magnesium in the blood.

HYPERMOBILITY. Unusual flexibility of the joints, allowing them to be bent or moved beyond their normal range of motion.

HYPEROSMOTIC. Hypertonic, containing a higher concentration of salts or other dissolved materials than normal tissues.

HYPEROSMOTIC DRUGS. Refers to a class of drugs for glaucoma that increase the osmotic pressure in the blood, which then pulls water from the eye into the blood.

HYPERPARATHYROIDISM. Over-functioning of the parathyroid glands. Symptoms include generalized aches and pains, depression, and abdominal pain.

HYPERPIGMENTATION. A skin condition that occurs when the body has too much melanin, or pigment.

HYPERPLASIA. An overgrowth of normal cells within an organ or tissue.

HYPERPLASTIC OBESITY. Excessive weight gain in childhood, characterized by an increase in the number of fat cells.

HYPERSECRETORY. Excessive production of a bodily secretion.

HYPERSENSITIVITY. An excessive response by the body to a foreign substance.

HYPERSOMNIA. An abnormal increase in time spent sleeping, usually accompanied by excessive daytime sleepiness.

HYPERSPLENISM. A syndrome marked by enlargement of the spleen, defects in one or more types of blood cells, and a high turnover of blood cells.

HYPERTENSION. High blood pressure.

HYPERTENSIVE HEART DISEASE. High blood pressure resulting in a disease of the heart.

HYPERTHERMIA THERAPY. A type of treatment in which body tissue is exposed to high temperatures to damage and kill cancer cells or to make cancer cells more sensitive to the effects of radiation and certain anticancer drugs.

HYPERTHYROID. Having too much thyroxin stimulation.

HYPERTHYROIDISM. A condition in which the thyroid gland in the throat is overactive and produces too much thyroid hormone.

HYPERTONIA. Having excessive muscular tone.

HYPERTROPHIC. Enlarged.

HYPERTROPHIC OBESITY. Excessive weight gain in adulthood, characterized by expansion of pre-existing fat cells.

HYPERTROPHY. The overgrowth of body tissue.

HYPERURICEMIA. Excessively high levels of uric acid in the blood.

HYPERVENTILATION. Rapid, deep breathing, possibly exceeding 40 breaths/minute. The most common cause is anxiety.

HYPERVIGILANCE. A condition of abnormally intense watchfulness or wariness. Hypervigilance is one of the most common symptoms of PTSD.

HYPERVISCOSITY. Thick, viscous blood, caused by the accumulation of large proteins, such as immunoglobulins, in the serum.

HYPERVITAMINOSIS. Another name for vitamin toxicity.

HYPNOGOGIC HALLUCINATION. A hallucination, such as the sensation of falling, that occurs at the onset of sleep.

HYPNOPOMPIC HALLUCINATION. A hallucination that occurs as a person is waking from sleep.

HYPNOSIS. An induced trance state, often characterized by extreme relaxation and suggestibility.

HYPNOTIC. A medication that causes sleep.

HYPNOTIC AGENT. A drug capable of inducing a hypnotic state.

HYPNOTIC STATE. A state of heightened awareness that can be used to modulate the perception of pain.

HYPOCALCEMIA. Low blood calcium.

HYPOCHROMIC. A descriptive term applied to a red blood cell with a decreased concentration of hemoglobin.

HYPOGLYCEMIA. Too little glucose or sugar in the blood.

HYPOGONADISM. Functional incompetence of the male gonads, with impaired production of hormones and germ cells.

HYPOKALEMIA. An abnormally low level of potassium in the blood.

HYPOMAGNESEMIA. An abnormally low concentration of magnesium in the blood.

HYPOMANIA. A less severe form of elevated mood state that is a characteristic of bipolar type II disorder.

HYPONATREMIA. A deficiency of sodium in the blood.

HYPOPARATHYROIDISM. Insufficient production of parathyroid hormone, caused by under-functioning of the parathyroid glands.

HYPOPIGMENTATION. A skin condition that occurs when the body has too little melanin, or pigment.

HYPOPITUITARISM. Underactivity of the pituitary gland.

HYPOPLASIA. Incomplete development of a body tissue or structure.

HYPOPLASTIC. Incomplete or underdevelopment of a tissue or organ. Hypoplastic left heart syndrome is the most serious type of congenital heart disease.

HYPOPLASTIC ANEMIA. Anemia caused by defective function of the blood-forming organs (such as bone marrow).

HYPOPNEA. Shallow or excessively slow breathing usually caused by partial closure of the upper airway during sleep, leading to disruption of sleep.

HYPOPROTEINEMIA. Abnormally low levels of protein in the blood.

HYPOPYON. A small amount of pus or collection of white cells that is visible in the front of the eye in severe cases of anterior uveitis.

HYPOSPADIAS. A congenital deformity of the penis where the urinary tract opening is not at the tip of the glans.

HYPOTENSION. Low blood pressure.

HYPOTHALAMIC-PITUITARY-GONADAL (HPG) AXIS. A term used by doctors to refer to the combined effects of the hypothalamus, the pituitary gland, and the gonads.

HYPOTHALAMUS. A structure within the brain responsible for a large number of normal functions throughout the body, including regulating sleep, body temperature, hunger, and sexual development. The hypothalamus also regulates the functions of the pituitary gland by directing the pituitary to stop or start production of its hormones.

HYPOTHERMIA. Low body temperature.

HYPOTHYROID. Having too little thyroxin stimulation.

HYPOTHYROIDISM. A disorder in which the thyroid gland produces too little thyroid hormone, causing a decreased rate of metabolism.

HYPOTONIA. Reduced or diminished muscle tone.

HYPOVENTILATION. Reduced ventilation in the lungs' air sacs resulting in above normal carbon dioxide pressure.

HYPOVOLEMIC SHOCK. Shock caused by a lack of circulating blood.

HYPOXEMIA. An abnormally low amount of oxygen in the blood, the major consequence of respiratory failure, when the lungs no longer are able to perform their chief function of gas exchange.

HYPOXIA. The medical term for deprivation of an adequate oxygen supply, either to specific tissues or to the entire organism.

HYSTERECTOMY. Removal of the uterus (with or without removal of the ovaries) by surgery. The surgery can be performed through an incision in the abdomen, or the uterus can be removed through the vagina.

HYSTERIA. The earliest term for a psychoneurotic disturbance marked by emotional outbursts and/or disturbances of movement and sense perception. Some forms of hysteria are now classified as somatoform disorders and others are grouped with the dissociative disorders.

HYSTERICAL NEUROSIS. An older term for conversion disorder or dissociative disorder.

HYSTEROSALPINGOGRAPHY; HSG. X raying of the uterus and fallopian tubes following the injection of a contrast dye.

HYSTEROSCOPY. A procedure in which an endoscope is inserted through the cervix to view the cervix and uterus.

I

I&D. Incision and drainage of a wound.

IATROGENIC. Inadvertently caused by medical treatment.

IATROGENIC KAPOSI'S SARCOMA. A form of Kaposi's sarcoma that develops in transplant patients who take immunosuppressive drugs to prevent rejection of their organ transplant.

ICHTHYOSIS. A group of congenital disorders of keratinization characterized by dryness and scaling of the skin.

ICSI. Stands for intracytoplasmic sperm injection. This process is used to inject a single sperm into each egg before the fertilized eggs are put back into the woman's body. The procedure may be used if the male has a low sperm count.

ICTAL EEG. Used to measure brain activity during a seizure. May be useful in learning more about patients who aren't responding to conventional treatments.

ICTERUS. Jaundice.

IDEAL WEIGHT. Weight corresponding to the lowest death rate for individuals of a specific height, gender, and age.

IDENTIFICATION WITH AN AGGRESSOR. In psychology, an unconscious process in which a person adopts the perspective or behavior patterns of a captor or abuser. Some researchers consider it a partial explanation of Stockholm syndrome.

IDENTIFIED PATIENT (IP). The family member in whom the family's symptom has emerged or is most obvious.

IDIOPATHIC. Refers to a disease that arises from an obscure or unknown cause.

IDIOPATHIC CARDIOMYOPATHY. Cardiomyopathy without a known cause.

IDIOSYNCRASY. A defect in that particular pathway resulting in an abnormality.

ILEUM. The lowest part of the small intestine, located beyond the duodenum and jejunum, just before the large intestine (the colon).

ILEUS. Obstruction of the intestines caused by the absence of peristalsis.

ILIAC ARTERY. Large blood vessel in the pelvis that leads into the leg.

ILIZAROV FRAME. A device invented by a Russian physician for correcting deformities of the legs and feet, consisting of rings to be attached to the bone and rods extending between the rings that stretch the affected limb.

ILLUSION. A false visual perception of an object that others perceive correctly.

IMIQUIMOD. A drug, approved by the FDA to treat warts, that may destroy basal cell carcinomas by stimulating the immune system. Also known by its trade name Aldara.

IMMEDIATE HYPERSENSITIVITY REACTIONS. Allergic reactions that are mediated by mast cells and occur within minutes of allergen contact.

IMMUNE COMPLEXES. Clusters or aggregates of antigen and antibody bound together.

IMMUNE FUNCTION. The body's defense system against bacteria, viruses and fungi, and any malfunction of the organism.

IMMUNE GLOBULIN. Serum containing antibodies against a specific infection.

IMMUNE OR IDIOPATHIC THROMBOCYTOPENIC PURPURA (ITP). A blood disease that results in destruction of platelets, which are blood cells involved in clotting.

IMMUNE RESPONSE. The protective reaction by the immune system against foreign antigens (substances that the body perceives as potentially dangerous). The immune system combats disease by neutralizing or destroying antigens.

IMMUNE SUPPRESSANT DRUG. Any drug that dampens immune responses and decreases inflammation.

IMMUNE SUPPRESSING. Anything that reduces the activity of the immune system.

IMMUNE SYSTEM. The system of specialized organs, lymph nodes, and blood cells throughout the body, which work together to prevent foreign invaders (bacteria, viruses, fungi, etc.) from taking hold and growing.

IMMUNIZATION. Administering a vaccine that stimulates the body to create antibodies to a specific disease (immunity) without causing symptoms of the disease.

IMMUNOCOMPETENCE. An individual's ability to fight off infection.

IMMUNOCOMPROMISED. Refers to conditions in which the immune system is not functioning properly and cannot adequately protect the body from infection.

IMMUNODEFICIENCY. A disorder in which the immune system is ineffective or disabled due either to acquired or inherited disease.

IMMUNOELECTROPHORESIS. Use of an electrical field to separate proteins in a mixture (such as blood or urine), on the basis of the size and electrical charge of the proteins; followed by the detection of an antigen (such as IgM), using a specific antibody.

IMMUNOFLUORESCENT ASSAY (IFA). A blood test sometimes used to confirm ELISA results instead of using the Western blotting. In an IFA test, HIV antigen is mixed with a fluorescent compound and then with a sample of the patient's blood. If HIV antibody is present, the mixture will fluoresce when examined under ultraviolet light.

IMMUNOGLOBULIN (IG). A substance made by B cells that neutralizes specific disease-causing substances and organisms. Also called "antibody." Immunoglobulins are divided into five classes: IgA, IgD, IgE, IgG, and IgM.

IMMUNOGLOBULIN E (IGE). A type of protein in blood plasma that acts as an antibody to activate allergic reactions. About 50% of patients with allergic disorders have increased IgE levels in their blood serum.

IMMUNOGLOBULIN G (IGG). A group of antibodies against certain viral infections that circulate in the bloodstream. One type of IgG is specific against the mumps paramyxovirus.

IMMUNORESISTANCE. The presence of circulating antibodies.

IMMUNOSUPPRESSANT. Any agent that decreases the response of the immune response of an individual.

IMMUNOSUPPRESSED. A state in which the immune system is suppressed by medications during the treatment of other disorders, such as cancer, or following an organ transplantation.

IMMUNOSUPPRESSION. The use of medications to suppress the immune system to prevent organ rejection.

IMMUNOSUPPRESSIVE CYTOTOXIC DRUGS. A class of drugs that function by destroying cells and suppressing the immune response.

IMMUNOSUPPRESSIVE DRUG. Medication used to suppress the immune system.

IMMUNOTHERAPY. A form of treatment that uses biologic agents to enhance or stimulate normal immune function.

IMPACTED TOOTH. A tooth that is growing against another tooth, bone, or soft tissue.

IMPACTION. A condition in which earwax has become tightly packed in the outer ear to the point that the external ear canal is blocked.

IMPERFORATE ANUS. A congenital malformation (a birth defect) in which the rectum is a blind alley (a cul-de-sac) and there is no anus.

IMPLANT. A fixture with one end implanted into the bone and the other end covered with a crown, often to serve as a stable abutment for a bridge or denture.

IMPLANTABLE CARDIOVERTER-DEFIBRILLATOR. A device placed in the body to deliver an electrical shock to the heart in response to a serious abnormal rhythm.

IMPLANTATION. The process in which the fertilized egg embeds itself in the wall of the uterus.

IMPOTENCE. The inability to achieve and sustain an erection suitable for intercourse.

IMPRESSION. An imprint of the upper or lower teeth made in a pliable material that sets. When this material has hardened, it may be filled with plaster, plastic, or artificial stone to make an exact model of the teeth.

IMPRINTING. Process that silences a gene or group of genes. The genes are silenced depending on if they are inherited through the egg or the sperm.

IN VITRO. A biological reaction occurring in a laboratory apparatus.

IN VIVO. Occurring in a living organism.

INBORN ERROR OF METABOLISM. A rare enzyme deficiency; children with inborn errors of metabolism do not have certain enzymes that the body requires to maintain organ functions. Inborn errors of metabolism can cause brain damage and mental retardation if left untreated. Phenylketonuria is an inborn error of metabolism.

INCARCERATED HERNIA. A hernia that cannot be reduced, or pushed back into place inside the abdominal wall.

INCARCERATION. The abnormal confinement of a section of the intestine or other body tissues. An umbilical hernia may lead to incarceration of part of the intestine.

INCENTIVE SPIROMETER. A breathing device that provides feedback on performance to encourage deep breathing.

INCEST. Sexual intercourse between people who are too closely related to legally marry.

INCISIONAL BIOPSY. Removal of a part of a lymph node for diagnostic purposes.

INCISORS. The eight front cutting teeth–four in the lower jaw and four in the upper jaw, located between the canines.

INCONTINENCE. Loss of ability to control urination or to control bowel movements (fecal incontinence).

INCREASED INTRACRANIAL PRESSURE. Increased overall pressure inside the skull.

INCUBATION. The time period between exposure to an infectious agent, such as a virus or bacteria, and the appearance of symptoms of illness.

INCUBATION PERIOD. The time it takes for symptoms to develop after initial exposure to a disease-causing organism.

INCUS. The middle of the three bones of the middle ear. It is also known as the "anvil."

INDEX OF REFRACTION. A constant number for any material for any given color of light that is an indicator of the degree of the bending of the light caused by that material.

INDIA INK TEST. A diagnostic test used to detect the cryptococcal organism *C. neoformans*. A dye, called India ink, is added to a sample of CSF fluid, and if the fungi is present, they will become visible as the dye binds to the capsule surrounding the fungus.

INDIGESTION. A feeling of discomfort or illness that results from the inability to properly digest food.

INDIUM. A silvery metallic element with some nonmetallic chemical properties used to label white blood cells prior to scanning.

INDOLENT LYMPHOMA (ALSO CALLED LOW-GRADE). Cancerous growths of lymphoid tissue that progress slowly to more aggressive forms of cancer.

INDURATION. An abnormally hard spot or area on the skin. The tuberculin skin test produces an induration at the test site in persons who have been exposed to TB.

INFANTICIDE. Intentional killing of a child within the first year of life.

INFANTILE SPASMS. Clusters of rapid jerks followed by stiffening or jackknife movements. Usually starts in the first year of life and stops by age 4.

INFARCT. Death of tissue due to shutting off the blood supply.

INFARCTION. An area of dead tissue caused by obstruction of the blood supply to that tissue.

INFECTIOUS DISEASE. Any disease caused by invasion of a pathogen that subsequently grows and multiplies in the body.

INFECTIOUS DISEASE TEAM. A team of physicians who help control the hospital environment to protect patients against harmful sources of infection.

INFERIOR VENA CAVA. The biggest vein in the body, returning blood to the heart from the lower half of the body.

INFERTILITY. The inability of a man and woman to conceive a child after 12 months of unprotected sexual intercourse.

INFESTATION. A condition in which a parasite develops and multiplies on the body of its host rather than inside the body.

INFIBULATION. A procedure that closes the labia majora to prevent sexual intercourse, leaving only a small opening for the passage of urine and menstrual blood.

INFILTRATES. Cells or body fluids that have passed into a tissue or body cavity.

INFILTRATING LOBULAR CARCINOMA. A type of cancer that accounts for 8% to 10% of breast cancers. In breasts that are especially dense, ultrasound can be useful in identifying these masses.

INFILTRATIVE. A process whereby inflammatory or other types of disease spread throughout an organ such as the lungs.

INFLAMED BOWEL. Irritation of the intestinal tract.

INFLAMMATION. The body's reaction to invasion by foreign matter, particularly infection. The result is swelling and redness from an increase in water and blood, and pain from the chemical activity of the reaction.

INFLAMMATORY BOWEL DISEASES. Ulcerative colitis or Crohn's disease: chronic conditions characterized by periods of diarrhea, bloating, abdominal cramps, and pain, sometimes accompanied by weight loss and malnutrition because of the inability to absorb nutrients.

INFLAMMATORY RESPONSE. The immune system's response to tissue injury caused by a physical, chemical, or biological substance.

INFLUENZA. A virus that affects the respiratory system, causing fever, congestion, muscle aches, and headaches.

INFORMED CONSENT. An educational process between health-care providers and patients intended to instruct the patient about the nature and purpose of the procedure or treatment, the risks and benefits of the procedure, and alternatives, including the option of not proceeding with the test or treatment.

INFRASPINATUS. A muscle at the middle of the shoulder blade.

INFUSION. Introduction of a substance directly into a vein or tissue by gravity flow.

INGUINAL HERNIA. An opening, weakness, or bulge in the lining of the abdominal wall in the groin area, with protrusion of the large intestine.

INHALANT. Medicine that is breathed into the lungs.

INHALATION CHALLENGE TEST. A test given to diagnose asthma by asking the patient to breathe cold air, methacholine, histamine, or another airway irritant and measuring the decline (if any) in the forced expiratory volume (FEV1).

INHERITANCE PATTERN. Refers to dominant or recessive inheritance.

INHIBITION. Restraint of or interference with a biological process, such as the clumping of blood cells.

INJECTION. Forcing a fluid into the body by means of a needle and syringe.

INLAY. A filling that is made outside of the tooth and the cemented into place.

INNER EAR. The interior section of the ear, where sound vibrations and information about balance are translated into nerve impulses.

INNOCENT. The medical term for a harmless heart murmur.

INORGANIC MERCURY. Inorganic compounds such as mercuric oxide (HgO) and mercuric chloride ($HgCl_2$).

INOTROPIC DRUGS. Medications used to stimulate the heart beat.

INPATIENT SURGERY. Surgery that requires an overnight stay of one or more days in the hospital.

INSECTICIDE. A pesticide that kills insects.

INSIDIOUS. Progressing gradually and inconspicuously, but with serious effects.

INSIGHT-ORIENTED THERAPY. An approach to psychotherapy based on helping the client understand the existence of previously unconscious conflicts and the origin of maladaptive behavior in order to change it. Psychoanalysis is one form of insight-oriented therapy.

INSOMNIA. Prolonged or abnormal inability to obtain adequate sleep.

INSPECTION. The visual examination of the body using the eyes and a lighted instrument if needed. The sense of smell may also be used.

INSUFFLATION. Inflation of the abdominal cavity using carbon dioxide; performed prior to laparoscopy to give the surgeon space to maneuver surgical equipment.

INSULIN. A hormone secreted by the pancreas in response to high blood sugar levels that induces hypoglycemia. Insulin regulates the body's use of glucose and the levels of glucose in the blood by acting to open the cells so that they can intake glucose.

INSULIN RESISTANCE. An inability to respond to insulin, a hormone produced by the pancreas that helps the body to use glucose.

INSULINOMA. Tumor that arises from the insulin-producing cells in the pancreas.

INTEGUMENT. The medical name for the skin.

INTENTION TREMOR. A rhythmic purposeless shaking of the muscles that begins with purposeful (voluntary) movement. This tremor does not affect muscles that are resting.

INTERCEPTIVE ORTHODONTICS. Preventative orthodontics; early, simpler orthodontic treatment.

INTERDENTAL. Between the teeth.

INTERFERON. Potent immune–defense protein produced by viral–infected cells. Manufactured interferon is used as an anticancer and antiviral drug.

INTERFERON ALPHA. Potent immune-defense protein; used as an anti-cancer drug.

INTERMITTENT CLAUDICATION. Leg pain and weakness caused by walking.

INTERMITTENT EXPLOSIVE DISORDER. A personality disorder in which an individual is prone to intermittent explosive episodes of aggression during which he or she causes bodily harm or destroys property.

INTERNAL DERANGEMENT. A condition in which the cartilage disc in the temporomandibular joint lies in front of its proper position.

INTERNATIONAL UNIT (IU). A measurement of biological activity in which one IU is equal to one mg (milligram).

INTERPERSONAL THERAPY. An approach that includes psychoeducation about the sick role, and emphasis on the present and improving interpersonal dynamics and relationships. Interpersonal therapy is effective in treating adjustment disorders related to physical illness.

INTERSTITIAL. Refers to the connective tissue that supports the "working parts" of an organ, in the case of the lungs the air sacs.

INTERSTITIAL CYSTITIS. A chronic inflammatory condition of the bladder involving symptoms of bladder pain, frequent urination, and burning during urination.

INTERSTITIAL FLUID. The fluid between cells in tissues. Referred to as the liquid substance of the body.

INTERSTITIAL LUNG DISEASE. About 180 diseases fall into this category of breathing disorders. Injury or foreign substances in the lungs (such as asbestos fibers) as well as infections, cancers, or inherited disorders may cause the diseases. They can lead to breathing or heart failure.

INTERSTITIAL SPACES. Spaces within body tissues that are outside the blood vessels. Also known as interstitial compartments.

INTERVERTEBRAL DISK. Cylindrical elastic-like gel pads that separate and join each pair of vertebrae in the spine.

INTESTINE. Also called the bowels and divided into large and small intestine, they extend from the stomach to the anus, where waste products exit the body. The small intestine is about 20 ft (6.1m) long and the large intestine, about 5 ft (1.5m) long.

INTOXICATION. The mental, physical, or emotional state produced by a substance.

INTRA-ABDOMINAL PRESSURE. Pressure that occurs within the abdominal cavity. Pressure in this area builds up with coughing, crying, and the pressure exerted when bearing down with a bowel movement.

INTRACELLULAR PARASITE. An organism which can only feed and live within the cell of a different animal.

INTRACEREBRAL HEMORRHAGE. A cause of some strokes in which vessels within the brain begin bleeding.

INTRACRANIAL. Existing or occurring within the cranium; affecting or involving intracranial structures.

INTRACRANIAL HYPERTENSION. Abnormally high blood pressure within the skull.

INTRACUTANEOUS. Into the skin, in this case directly under the top layer of skin.

INTRAMUSCULARLY. A medication given by needle into a muscle.

INTRAOCULAR. Literally, within the eye.

INTRAOCULAR LENS. Lens made of silicone or plastic placed within the eye; can be corrective.

INTRAOCULAR LENS (IOL) IMPLANT. A small, plastic device (IOL) that is usually implanted in the lens capsule of the eye to correct vision after the lens of the eye is removed; used in cataract surgery.

INTRAOCULAR RETINOBLASTOMA. Cancer that is limited to the eye and has not spread to other parts of the body.

INTRATHECAL. Administration of chemotherapy drugs injected into the cerebrospinal fluids which surround the brain and spinal cord.

INTRATHECAL THERAPY. Injecting chemotherapy directly into the CSF using lumbar puncture.

INTRAUTERINE. Situated or occuring in the uterus.

INTRAUTERINE DEVICE (IUD). Contraceptive device consisting of a piece of bent plastic or metal that is inserted through the vagina into the uterus.

INTRAVENOUS. Into a vein; a needle is inserted into a vein in the back of the hand, inside the elbow, or some other location on the body. Fluids, nutrients, and drugs can be injected.

INTRAVENOUS PYELOGRAM (IVP). A procedure in which a dye is injected into a vein in the arm. The dye travels through the body and concentrates in the urine to be discharged. It outlines the kidneys, ureters, and the urinary bladder. An x-ray image is then made and any abnormalities of the urinary tract are revealed.

INTRAVENTRICULAR HEMORRHAGE (IVH). A condition in which blood vessels within the brain burst and bleed into the hollow chambers (ventricles) normally reserved for cerebrospinal fluid and into the tissue surrounding them.

INTRINSIC FACTOR. A substance produced by the parietal cells of the stomach. In order to be absorbed by the intestine, vitamin B_{12} must form a complex with intrinsic factor.

INTRINSIC PATHWAY. One of three pathways in the coagulation cascade.

INTRINSIC SPHINCTER DEFICIENCY (ISD). A factor in severe stress incontinence due to the inadequacy of the sphincter muscles to keep the bladder closed.

INTUBATION. The insertion of a tube into the patient's airway to protect the airway from collapsing. Intubation is sometimes done as an emergency procedure for patients with epiglottitis.

INTUSSUSCEPTION. The slipping or telescoping of one part of the intestine into the section next to it.

INVASIVE. A diagnostic test that invades healthy tissue; in the case of venography, through an incision in a healthy vein.

INVASIVE SURGERY. A form of surgery that involves making an incision in the patient's body and inserting instruments or other medical devices into it.

ION. An atom or molecule that has an electric charge. In the body ions are collectively referred to as electrolytes.

IONIZING RADIATION. Radiation that can damage living tissue by disrupting and destroying individual cells at the molecular level. All types of nuclear radiation–x rays, gamma rays and beta rays–are potentially ionizing. Sound waves physically vibrate the material through which they pass, but do not ionize it.

IQ. Intelligence quotient; a measure of intellectual functioning determined by performance on standardized intelligence tests.

IRIDO CORNEAL ENDOTHELIAL SYNDROME; ICE. A type of glaucoma in which cells from the back of the cornea spread over the surface of the iris and tissue that drains the eye, forming adhesions that bind the iris to the cornea.

IRIS (PLURAL, IRIDES). The circular pigmented membrane behind the cornea of the eye that gives the eye its color. The iris surrounds a central opening called the pupil.

IRON OVERLOAD. A side effect of frequent blood transfusions in which the body accumulates abnormally high levels of iron. Iron deposits can form in organs, particularly the heart, and cause life–threatening damage.

IRON POISONING. A potentially fatal condition caused by swallowing large amounts of iron dietary supplements.

IRRIGATION. In medicine, the practice of washing out or flushing a wound or body opening with a stream of water or another liquid.

IRRITABLE BOWEL DISEASE. An intestinal disorder often accompanied by abdominal pain and diarrhea.

ISCHEMIA. A condition in which blood flow is cut off or restricted from a particular area. The tissue becomes starved of oxygen and nutrients, resulting in tissue death.

ISCHEMIC. An inadequate supply of blood to a part of the body, caused by partial or total blockage of an artery.

ISCHEMIC HEART DISEASE. Insufficient blood supply to the heart muscle (myocardium).

ISLETS OF LANGERHANS. Special structures in the pancreas responsible for insulin secretion among other functions. They are named for Paul Langerhans, the German researcher who first identified them in 1869.

ISOENZYME. One of a group of enzymes that catalyze the same reaction but are differentiated by variations in physical properties.

ISOMETRIC EXERCISES. Exercises which strengthen through muscle resistance.

ISOSPORA BELLI. A type of parasitic protozoa.

ISOTOPE. Any of two or more species of atoms of a chemical element with the same atomic number and nearly identical chemical behavior but with differing atomic mass and physical properties.

ISOTRETINOIN. A drug for severe acne that decreases sebum production and dries up pimples.

ISOZYME. One of a group of enzymes that perform the same function, but are different from one another in their structure or the way in which they move.

J

JARISCH-HERXHEIMER REACTION. A temporary reaction to penicillin treatment for syphilis that includes fever, chills, and worsening of the skin rash or chancre.

JAUNDICE. A condition that results in a yellow tint to the skin, eyes and body fluids. Bile retention in the liver, gallbladder and pancreas is the immediate cause, but the underlying cause could be as simple as obstruction of the common bile duct by a gallstone or as serious as pancreatic cancer.

JEJUNOSTOMY. Surgical creation of an opening to the middle portion of the small intestine (jejunum), through the abdominal wall.

JEJUNUM. The middle portion of the small intestine. It is approximately 8 ft (2.5 m) long and extends from the jejunum to the ileum.

JET LAG. A temporary disruption of the body's sleep-wake rhythm following high-speed air travel across several time zones. Jet lag is most severe in people who have crossed eight or more time zones in 24 hours.

JOINT. The point of connection between two bones that allows motion.

JOINT CONTRACTURES. Stiffness of the joints that prevents full extension.

JOINT DISLOCATION. The displacement of a bone.

K

KALLMANN SYNDROME. A rare genetic disorder in which the hypothalamus does not produce enough gonadotropin–releasing hormone, leading to underfunctioning of the testes in males and the ovaries in females.

KAPOSI'S SARCOMA. A cancer of the connective tissue that produces painless purplish red (in people with light skin) or brown (in people with dark skin) blotches on the skin. It is a major diagnostic marker of AIDS.

KARYOTYPE. A standard arrangement of photographic or computer–generated images of chromosome pairs from a cell in ascending numerical order, from largest to smallest.

KARYOTYPING. A laboratory procedure in which chromosomes are separated from cells, stained, and arranged so that their structure can be studied under the microscope.

KEGEL EXERCISES. Repetitive contractions to tone the pubococcygeal muscle of the pelvic floor for enhancing sexual response during intercourse or controlling incontinence.

KELOID. An unusual or abnormal growth of scar tissue, as in the third stage of granuloma inguinale.

KERATIN. A tough, nonwater-soluble protein found in the nails, hair, and the outermost layer of skin. Human hair is made up largely of keratin.

KERATINOCYTES. Cells found in the epidermis. The keratinocytes at the outer surface of the epidermis are dead and form a tough protective layer. The cells underneath divide to replenish the supply.

KERATOCONJUNCTIVITIS. Inflammation of the conjunctiva and cornea of the eye.

KERATOCONUS. An eye condition in which the cornea bulges outward, interfering with normal vision. Usually both eyes are affected.

KERATODERMA BLENNORRHAGICA. The medical name for the patches of scaly skin that occur on the arms, legs, and trunk of RS patients.

KERATOLYTIC. An agent that dissolves or breaks down the outer layer of skin (keratins).

KERATOMALACIA. Keratomalacia is ulceration of the cornea.

KERION. A raised boggy or swollen patch of reddened skin that develops as a complication of ringworm.

KERNICTERUS. A serious condition in which bilirubin deposits in the brain leading to permanent neurological damage and potentially death.

KETOACIDOSIS. A condition due to starvation or uncontrolled Type I diabetes. Ketones are acid compounds that form in the blood when the body breaks down fats and proteins. Symptoms include abdominal pain, vomiting, rapid breathing, extreme tiredness, and drowsiness.

KETOGENIC DIET. A diet that supplies an abnormally high amount of fat, and small amounts of carbohydrates and protein.

KETONES. Poisonous acidic chemicals produced by the body when fat instead of glucose is burned for energy. Breakdown of fat occurs when not enough insulin is present to channel glucose into body cells.

KETOSIS. An abnormal increase in ketones in the body, usually found in people with uncontrolled diabetes mellitus.

KIDNEY. Either of two organs in the lumbar region that filter the blood, excreting the end products of the body's metabolism in the form of urine and regulating the concentrations of hydrogen, sodium, potassium, phosphate and other ions in the body.

KIDNEY DIALYSIS. A process during which blood is filtered through a dialysis machine to remove waste products that would normally be removed by the kidneys. The filtered blood is then circulated back into the patient. This process also is called renal dialysis.

KIDNEY DISEASE. Any disorder that impairs the kidney's ability to remove waste and toxins from the body.

KIDNEY FAILURE. The inability of the kidney to excrete toxic substances from the body.

KIDNEY STONE. A hard mass that forms in the urinary tract and can cause pain, bleeding, obstruction, or infection. Stones are primarily made up of calcium.

KIESSELBACH'S PLEXUS. An area on the anterior part of the nasal septum that has a rich supply of blood vessels and is a common site of nosebleeds. It is named for Wilhelm Kiesselbach, a nineteenth-century German otolaryngologist.

KINESIOLOGY. The study of the anatomy and physiology of body movement.

KLEINE-LEVIN SYNDROME. A disorder that occurs primarily in young males, with episodes three or four times a year. The syndrome is marked by bouts of hypersomnia, hypersexual behavior, and excessive eating.

KLEPTOMANIA. An impulse control disorder characterized by the overwhelming urge to steal.

KLINEFELTER SYNDROME. A condition caused by extra X chromosome(s) in a male, which results in small testes and infertility together with increased height, decreased facial hair, and sometimes breast enlargement.

KOCK POUCH. A type of ileostomy in which the surgeon forms an artificial rectum from a section of the ileum. A Kock pouch is sometimes called a continent ileostomy because it is drained with a tube.

KOH. The chemical formula for potassium hydroxide, which is used to perform the KOH test. The test is also called a potassium hydroxide preparation.

KOPLIK'S SPOTS. Tiny spots occurring inside the mouth, especially on the inside of the cheek. These spots consist of minuscule white dots (like grains of salt or sand) set onto a reddened bump. Unique to measles.

KOSHER. Conforming to Jewish dietary laws.

KWASHIORKOR. Severe malnutrition in children primarily caused by a protein-poor diet, characterized by growth retardation.

KYPHOSCOLIOSIS. Abnormal front-to-back and side-to-side curvature of the spine.

KYPHOSIS. An abnormal outward curvature of the spine, with a hump at the upper back.

L

LABIA. The fatty folds of the vulva.

LABIA MAJORA. Major lips; mounds of tissue forming the lateral boundaries of the vulva.

LABIA MINORA. Minor lips; narrow folds of tissue between the labia major, on either side of the urethral and vaginal openings.

LABOR. The process during which the uterus contracts and the cervix opens to allow the passage of a baby into the vagina.

LABYRINTH. The bony cavity of the inner ear.

LACERATION. Also called a tear. Separation of skin or other tissue by a tremendous force, producing irregular edges.

LACRIMAL DUCT. A short canal leading from a small orifice at the medial angle of each eyelid to the lacrimal sac.

LACRIMAL GLAND. An almond-shaped gland that secretes tears.

LACRIMAL SAC. The dilated upper end of the nasolacrimal duct in which the lacrimal ducts empty.

LACTASE. The enzyme needed to break down lactose, the sugar found in milk.

LACTASE ENZYME. The enzyme produced by cells lining the small intestine that allows the body to break down lactose.

LACTATION. Secretion of milk from the breasts; the act of breastfeeding.

LACTIC ACIDOSIS. A serious condition caused by the build up of lactic acid in the blood, causing it to become excessively acidic. Lactic acid is a by-product of glucose metabolism.

LACTOBACILLUS ACIDOPHILUS. A bacteria found in yogurt that changes the balance of the bacteria in the intestine in a beneficial way.

LACTOSE. A sugar found in milk that provides energy.

LACTOSE INTOLERANCE. An inability to properly digest milk and dairy products.

LAMELLAR ICHTHYOSIS. Also called fish scale disease, this inherited condition is characterized by darkened, scaly, dry patches of skin.

LAMINAE (SINGULAR, LAMINA). The broad plates of bone on the upper surface of the vertebrae that fuse

together at the midline to form a bony covering over the spinal canal.

LAMINARIA. A medical product made from a certain type of seaweed that is physically placed near the cervix to cause it to dilate.

LAMINECTOMY. An operation in which the surgeon cuts through the covering of a vertebra to reach a herniated disk in order to remove it.

LAMINOTOMY. A less invasive alternative to a laminectomy in which a hole is drilled through the lamina.

LANUGO. A soft, downy body hair that develops on the chest and arms of anorexic women.

LAPAROSCOPE. A pencil-thin telescope that allows surgery to be done through half-inch incisions.

LAPAROSCOPIC. A minimally invasive surgical or diagnostic procedure that uses a flexible endoscope (laparoscope) to view and operate on structures in the abdomen.

LAPAROSCOPIC CHOLECYSTECTOMY. Removal of the gallbladder using a laparoscope, a fiberoptical instrument inserted through the abdomen.

LAPAROSCOPIC PROCEDURES. Surgical procedures performed using a laparoscope—a pencil-thin instrument that has its own lighting system and miniature video camera. To perform surgeries, only small incisions are needed to insert the instruments and the miniature camera.

LAPAROSCOPIC SURGERY. A minimally invasive surgery in which a camera and surgical instruments are inserted through a small incision.

LAPAROSCOPY. Procedure using a laparoscope to view organs, obtain tissue samples, and perform surgery.

LAPAROTOMY. Surgical incision into the abdomen to locate, repair, and/or remove injured or diseased tissues.

LARGE CORE NEEDLE BIOPSY. A procedure using a thicker needle to remove a core of tissue, about the size of a grain of rice, from the breast.

LARVA. The immature, early form of an organism that at birth or hatching is not like its parent and has to undergo metamorphosis before assuming adult features.

LARYNGECTOMY. Surgical removal of the larynx to treat cancer.

LARYNGITIS. Inflammation of the larynx (voice box).

LARYNGOSCOPE. A diagnostic instrument that is used to examine the interior of the larynx.

LARYNGOSCOPY. A medical procedure that uses flexible, lighted, narrow tubes inserted through the mouth or nose to examine the larynx and other areas deep inside the neck.

LARYNGOSPASM. Spasm of the larynx.

LARYNX. Also known as the voice box, the larynx is composed of cartilage that contains the apparatus for voice production. This includes the vocal cords and the muscles and ligaments that move the cords.

LASER. A device that concentrates electromagnetic radiation into a narrow beam and treats tissue quickly without heating surrounding areas.

LASER CYCLOPHOTOCOAGULATION. A procedure used for severe glaucoma in patients who have not responded well to previous treatments. The laser partially destroys the tissues that make the fluid of the eye.

LASER PERIPHERAL IRIDOTOMY. This procedure makes a drainage hole in the iris allowing the fluid to drain from the eye.

LASER TRABECULOPLASTY. In this procedure, the laser attempts to open the normal drainage channels of the eye so fluid can drain more effectively.

LASER-ASSISTED IN-SITU KERATOMILEUSIS (LASIK). A surgical procedure that uses a cutting tool and a laser to modify the cornea and correct moderate to high levels of myopia.

LATCH-ON. The process whereby the baby opens the mouth widely and first exerts negative pressure on the mother's nipple and then positive pressure. Good latch-on will result in adequate transfer of milk into the baby's mouth and prevent sore nipples from occurring.

LATE DECELERATION. Transient slowing of the fetal heart (brachycardia), which reaches its height more than 30 seconds after the peak of the uterine contraction and may indicate the fetus is not receiving enough oxygen (hypoxia).

LATENCY. The period of inactivity between the time a stimulus is provided and the time a response occurs.

LATENT VIRUS. An inactive virus that is in a dormant state within a cell.

LATEX. A rubber material that gloves and condoms are made from.

LAVAGE. The washing out of a hollow body organ—for example, the stomach—using a flow of water.

LAW OF SIMILARS. The basic principle of homeopathic medicine that governs the selection of a specific remedy. It holds that a substance of natural origin that produces certain symptoms in a healthy person will cure those same symptoms in a sick person.

LAXATIVE. Material that encourages a bowel movement.

LDL CHOLESTEROL. Low-density lipoprotein cholesterol is the primary cholesterol molecule. High levels of LDL increase the risk of coronary heart disease. LDL is nicknamed "bad cholesterol."

LEAD. Name given the electrode when it is attached to the skin.

LEARNING DISORDER. An impairment of the cognitive processes of understanding and using spoken and written language that results in difficulties with one or more academic skill sets (e.g., reading, writing, mathematics).

LEEP. Loop Electrosurgical Excision Procedure.

LEFT ANTERIOR DESCENDING CORONARY ARTERY (LAD). One of the branches of the heart's left main coronary artery that supplies blood to the left ventricle.

LEFT VENTRICLE. The large chamber on the lower left side of the heart. The left ventricle sends blood to the aorta and the rest of the body.

LEGIONELLOSIS. A disease caused by infection with a *Legionella* bacterium.

LEGUME. Group of plant foods including beans, peas, and lentils, which are high in protein, fiber, and other nutrients.

LEISHMAN-DONOVAN BODY. A body of a (trypanosomatid) protozoa at a particular and characteristic stage in its life cycle; the infectious (trypanosomatid) protozoa can cause leishmaniasis.

LENS. The transparent, elastic, curved structure behind the iris (colored part of the eye) that helps focus light on the retina.

LENTICONUS. A rare, usually congenital condition in which the surface of the lens of the eye is conical.

LEPTIN. A peptide hormone produced by fat cells that acts on the hypothalamus to suppress appetite and burn stored fat.

LESION. Any visible, local abnormality of the tissues of the skin, such as a wound, sore, rash, or boil.

LET. A topical anesthetic mixture containing lidocaine, epinephrine, and tetracaine.

LETHARGY. The state of being sluggish.

LEUKEMIA. A cancer of blood cells characterized by the abnormal increase in the number of white blood cells in the tissues. There are many types of leukemias and they are classified according to the type of white blood cell involved.

LEUKEMIA STAINS. Special stains added to smears of blood or bone marrow, performed to diagnose and classify leukemia.

LEUKOCORIA. A pupil reflex that is white instead of red or that has white spots.

LEUKOCYTE. A white blood cell. Leukocytes protect the body against infection and fight infection when it occurs; they are bigger than red blood cells.

LEUKOCYTE ADHESION DEFICIENCY SYNDROME. A complement deficiency syndrome characterized by recurrent infections of the skin, mucous membranes, and gastrointestinal tract and the absence of pus formation. This disorder is sometimes apparent at birth when separation of the umbilical cord takes longer than normal.

LEUKOCYTE ALKALINE PHOSPHATASE (LAP) TEST. A blood test that measures the level of enzyme activity in a type of white blood cell called neutrophils.

LEUKOCYTOSIS. An increased level of white cells in the blood. Leukocytosis is a common reaction to infections.

LEUKODYSTROPHY. Any of several inherited diseases characterized by the degeneration of myelin in the brain, spinal cord, and peripheral nerves.

LEUKOPENIA. A white blood cell count decreased to less than 4,000/μL.

LEUKOTRIENES. A class of small molecules produced by cells in response to allergen exposure; they contribute to allergy and asthma symptoms.

LEVODOPA (L–DOPA). A substance used in the treatment of Parkinson's disease. Levodopa can cross the blood-brain barrier that protects the brain. Once in the brain, it is converted to dopamine and thus can replace the dopamine lost in Parkinson's disease.

LEVONORGESTREL. A synthetic progestin used in emergency contraceptive pills.

LEWY BODIES. Areas of injury found on damaged nerve cells in certain parts of the brain associated with dementia.

LEYDIG CELLS. Cells that make up the endocrine tissue of the testis and produce testosterone. They are named for Franz von Leydig (1821–1908), the German professor of anatomy who first identified them.

LICHEN PLANUS. A noncancerous, chronic, itchy skin disease that causes small, flat, purple plaques on the wrists, forearms, and ankles.

LICHEN SIMPLEX CHRONICUS. A skin disorder accompanied by severe itching that causes thick, dark patches of skin to develop.

LIGAMENT. A type of connective tissue that connects bones or cartilage and provides support and strength to joints.

LIGAMENTA FLAVA (SINGULAR, LIGAMENTUM FLAVUM). A series of bands of tissue that are attached to the vertebrae in the spinal column. They help to hold the spine straight and to close the spaces between the laminar arches. The Latin name means "yellow band(s)."

LIMB-GIRDLE MUSCULAR DYSTROPHY. An autosomal recessive form of muscular dystrophy that appears anywhere from late childhood to middle age and is characterized by progressive muscular weakness beginning either in the shoulder or pelvic girdle; the disease usually progresses slowly with cardiopulmonary complications in the later stages.

LIMBIC SYSTEM. A group of structures in the brain that includes the hypothalamus, amygdala, and hippocampus. The limbic system plays an important part in regulation of human moods and emotions. Many psychiatric disorders are related to malfunctioning of the limbic system.

LIMITED SCLERODERMA. A subtype of systemic scleroderma with limited skin involvement. It is sometimes called the CREST form of scleroderma, after the initials of its five major symptoms.

LIMITED SUPPORT. A predetermined period of assistance required to deal with a specific event, such as training for a new job.

LINDANE. An organic chloride, neurotoxic insecticide that kills lice.

LINGUAL TONSILS. A pair of small tonsils located on the upper side of the base of the tongue.

LINOLEIC ACID. An unsaturated omega-6 fatty acid found in many plant oils that humans need in their diet. Plant oils rich in linoleic acid are beneficial to the skin when used in massage.

LIPASE. A fat-splitting enzyme found in pancreatic juice, blood, and many tissues.

LIPIDS. A group of fats and fat-like substances that are not soluble in water, are stored in the body, and serve as a source of fuel for the body.

LIPODYSTROPHY. The medical term for redistribution of body fat in response to highly active antiretroviral therapy, insulin injections in diabetics, or rare hereditary disorders.

LIPOMA. A usually benign tumor of fatty tissue.

LIPOPROTEIN. A complex molecule that consists of a protein membrane surrounding a core of lipids. Lipoproteins carry cholesterol and other lipids from the digestive tract to the liver and other body tissues. There are five major types of lipoproteins.

LIPOSHAVING. Involves removing fat that lies closer to the surface of the skin by using a needle-like instrument that contains a sharp-edged shaving device.

LIPOSUCTION. A cosmetic surgery technique for removing unwanted fat cells from the abdomen, hips, thighs, or male breast while doing as little damage as possible to nearby connective tissue and blood vessels.

LISTERIOSIS. A food-borne bacterial infection caused by *Listeria monocytogenes* to which pregnant women are particularly susceptible.

LITHIUM (LITHANE, LITHROMATE). Medication prescribed to treat manic (excited) phases of bipolar disorder.

LITHOTRIPSY. A nonsurgical technique for removing gallstones by breaking them apart with high-frequency sound waves.

LIVER. A solid organ located on the right in the upper abdomen. It plays a major role in metabolism, digestion, detoxification, and elimination of substances from the body.

LIVER BIOPSY. A surgical procedure where a small piece of the liver is cut out for examination. A needle or narrow tube may be inserted either directly through the skin and muscle or through a small incision and passed into the liver for collection of a sample of liver tissue.

LIVER ENCEPHALOPATHY. A condition in which the brain is affected by a buildup of toxic substances that would normally be removed by the liver. The condition occurs when the liver is too severely damaged to cleanse the blood effectively.

LIVER FUNCTION TESTS. Tests used to evaluate liver metabolism, storage, filtration, and excretion. The tests include alkaline phosphatase, alanine aminotransferase, and aspartate aminotransferase.

LIVING WILL. A legal document detailing a person's wishes during the end of life, to be carried out by designated decision makers.

LOBAR. Relating to a lobe.

LOBAR HEMORRHAGE. Bleeding into one of the lobes of the brain.

LOBULES. A small lobe or subdivision of a lobe (often on a gland) that may be seen on the surface of the gland by bumps or bulges.

LOCAL ANESTHETIC. Medication applied topically to the skin or administered through an injection that deadens a specific part of the body and inhibits the sensation of pain.

LOCALIZED. Confined to a small area.

LOCALIZED SCLERODERMA. Thickening of the skin from overproduction of collagen.

LOCUS CERULEUS. Area in the brain stem that processes sensory signals from all areas of the body.

LODESTONE. A variety of magnetite that possesses magnetic polarity.

LOEFFLER'S MEDIUM. A special substance used to grow diphtheria bacilli to confirm a diagnosis.

LOEFFLER'S SYNDROME. The respiratory phase of ascariasis, marked by inflammation of the lungs and eosinophilia.

LONG-STRETCH BANDAGES. Specialized bandages, similar to an Ace bandage, that have 100% to 200% stretch.

LOOP ELECTROSURGICAL EXCISION (LEEP). A procedure that can help diagnose and treat cervical abnormalities using a thin wire loop that emits a low-voltage high-frequency radio wave that can excise tissue.

LOW TRANSVERSE INCISION. Incision made horizontally across the lower end of the uterus.

LOW-DENSITY LIPOPROTEIN (LDL). A type of lipoprotein that consists of about 50% cholesterol and is associated with an increased risk of coronary artery disease.

LOWER ESOPHAGEAL SPHINCTER (LES). A muscular ring at the base of the esophagus that keeps stomach contents from entering back into the esophagus.

LOWER EXTREMITY AMPUTATION. To cut a limb from the lower body.

LOW-STRETCH BANDAGE. Specialized bandages with 30% to 90% stretch that are used to obtain the correct compression during the treatment of lymphedema; also known as short-stretch bandages.

LUES MALIGNA. Areas of ulcerated and dying skin tissue that may occur with secondary syphilis, most frequently in HIV-positive patients.

LUGOL'S SOLUTION. A strong iodine solution.

LUMBAR. Pertaining to the part of the back between the chest and the pelvis.

LUMBAR PUNCTURE. Also called a spinal tap, a procedure in which a thin needle is used to withdraw a sample of cerebrospinal fluid for diagnostic purposes from the area surrounding the spine.

LUMBAR SPINE. The segment of the human spine above the pelvis that is involved in low back pain. There are five vertebrae, or bones, in the lumbar spine.

LUMBAR VERTEBRAE. The vertebrae of the lower back below the level of the ribs.

LUMBOSACRAL. Referring to the lower part of the backbone or spine.

LUMEN. The cavity or channel inside a blood vessel or tube-shaped organ.

LUMPECTOMY. A surgical procedure in which only the cancerous tumor in the breast is removed, together with a rim of normal tissue.

LUNG FUNCTION TESTS. Tests of how much air the lungs can move in and out, and how quickly and efficiently this can be done. Lung function tests are usually done by breathing into a device that measures air flow.

LUNG NODULE. See pulmonary nodule.

LUPUS (SYSTEMIC LUPUS ERYTHEMATOSUS OR SLE). A chronic inflammatory autoimmune disorder that may affect many organ systems including the skin, joints, and internal organs.

LUTEINIZING HORMONE. A hormone secreted by the pituitary gland that regulates the menstrual cycle

and triggers ovulation in females. In males, it stimulates the testes to produce testosterone.

LUTEINIZING HORMONE RELEASING HORMONE (LHRH) AGONIST. A substance that blocks the action of LHRH, a hormone that stimulates the production of testosterone (a male hormone) in men. Used to treat prostate cancers that require testosterone for growth.

LUTROPIN. Another term for luteinizing hormone, this hormone stimulates the development and release of the egg from the ovary.

LUX. The International System unit for measuring illumination, equal to one lumen per square meter.

LUXATE. To loosen or dislocate the tooth from the socket.

LYME DISEASE. An acute recurrent inflammatory disease involving one or a few joints, believed to be transmitted by a tick-borne virus. The condition was originally described in the community of Lyme, Connecticut, but has also been reported in other parts of the United States and other countries. Knees and other large joints are most commonly affected, with symptoms including local inflammation and swelling.

LYMPH. A clear fluid that contains cells important in forming antibodies that fight infection; also known as lymphatic fluid.

LYMPH NODE DISSECTION. Surgical removal of a group of lymph nodes.

LYMPH NODES. Oval-shaped organs the size of peas that are located throughout the body and contain clusters of cells called lymphocytes. They filter out and destroy bacteria, foreign particles, and cancerous cells from the blood.

LYMPHANGIOGRAPHY. Injection of dye into lymphatic vessels followed by x rays of the area. It is a difficult procedure, as it requires surgical isolation of the lymph vessels to be injected.

LYMPHANGITIS. Inflammation of the lymphatic vessels. It often occurs together with lymphadenitis.

LYMPHATIC SYSTEM. Also referred to as the lymph system, a network of vessels, nodes, and organs responsible for filtering and transporting fluid and nutrients to the bloodstream; serves as an important part of the immune system.

LYMPHATIC VESSELS. Vessels that carry lymph from the tissues to the bloodstream; also referred to as lymph channels or lymphatics.

LYMPHEDEMA. The unnatural accumulation of lymph in the tissues of the body, which results in swelling in that area.

LYMPHOCYTES. Type of white blood cells that are part of the immune system. The lymphocytes are composed of three main cell lines: B lymphocytes, T lymphocytes, and natural killer (NK) cells.

LYMPHOCYTOSIS. A condition in which the number of lymphocytes increases above normal levels.

LYMPHOID. Tissues relating to the lymphatic system.

LYMPHOID TISSUE. Sites within the body that produce cells of the immune system, including lymph nodes, bone marrow, and the thymus.

LYMPHOMA. A blood cancer in which lymphocytes, a variety of white blood cells, grow at an unusually rapid rate.

LYMPHOPENIA. A condition in which the number of lymphocytes falls below normal levels.

LYMPHOSCINTIGRAPHY. A technique in which a radioactive substance that concentrates in the lymphatic vessels is injected into the affected tissue and mapped using a gamma camera, which images the location of the radioactive tracer.

LYSOSOME. Membrane-enclosed compartment in cells, containing many hydrolytic enzymes, where large molecules and cellular components are broken down.

LYSSAVIRUS. A genus of viruses that includes the rabies virus and related viruses that infect insects as well as mammals.

LYSYL OXIDASE. An enzyme required for the cross-linking of elastin and collagen molecules to form properly functioning connective tissue.

M

M PROTEIN. Monoclonal or myeloma protein; abnormal antibody found in large amounts in the blood and urine of individuals with multiple myeloma.

MACROBIOTIC DIET. A diet based primarily on whole grains, vegetables, and beans, avoiding refined or processed foods.

MACROCYTIC. A descriptive term applied to a larger-than-normal red blood cell.

MACROMASTIA. Excessive size of the breasts.

MACROPHAGE. A cell of the immune system that engulfs and digests foreign invaders such as bacteria and viruses in an attempt to stop them from causing disease within the body.

MACULA. The sensitive center of the retina that is responsible for detailed central vision.

MACULAR DEGENERATION. A condition usually associated with age in which the area of the retina called the macula is impaired due to hardening of the arteries (arteriosclerosis). This condition interferes with vision.

MACULE. A flat, discolored area on the skin.

MACULOPAPULAR RASH. A rash characterized by raised, spotted lesions.

MAGNETIC FIELD. The three-dimensional area surrounding a magnet, in which its force is active.

MAGNETIC RESONANCE ANGIOGRAPHY. A noninvasive diagnostic technique that uses radio waves to map the internal anatomy of the blood vessels.

MAGNETIC RESONANCE IMAGING (MRI). An imaging technique that uses a large circular magnet and radio waves to generate signals from atoms in the body. These signals are used to construct images of internal structures.

MAJOR DEPRESSIVE DISORDER. A mood disorder characterized by profound feelings of sadness or despair.

MAJOR TRANQUILIZERS. The family of drugs that includes the psychotropic or neuroleptic drugs, sometimes used to help autistic people. They carry significant risk of side effects, including Parkinsonism and movement disorders, and should be prescribed with caution.

MALABSORPTION. Poor absorption of materials in the digestive system.

MALABSORPTION SYNDROME. A condition characterized by indigestion, bloating, diarrhea, loss of appetite, and weakness, caused by poor absorption of nutrients from food.

MALADAPTIVE. Unsuitable or counterproductive; for example, maladaptive behavior is behavior that is inappropriate to a given situation.

MALARIA. Disease caused by the presence of sporozoan parasites of the genus *Plasmodium* in the red blood cells, transmitted by the bite of anopheline mosquitoes, and characterized by severe and recurring attacks of chills and fever.

MALATHION. An organic phosphate, neurotoxic insecticide that kills lice.

MALIGNANCY. A locally invasive and destructive growth.

MALIGNANT. The term literally means growing worse and resisting treatment. It is used as a synonym for cancerous and connotes a harmful condition that generally is life threatening.

MALIGNANT HYPERTHERMIA. A type of reaction (probably with a genetic origin) that can occur during general anesthesia and in which the patient experiences a high fever, muscle rigidity, and irregular heart rate and blood pressure.

MALIGNANT MELANOMA. A potentially fatal form of skin cancer that develops from melanocytes, which are skin cells containing melanin.

MALIGNANT MESOTHELIOMA. A cancer of the pleura (the membrane lining the chest cavity and covering the lungs) that typically is related to asbestos exposure.

MALIGNANT TUMOR. An abnormal proliferation of cells that can spread to other sites.

MALINGERING. Pretending to be sick in order to be relieved of an unwanted duty or obtain some other obvious benefit.

MALLEUS. One of the three bones of the middle ear; also known as the "hammer."

MALOCCLUSION. The misalignment of opposing teeth in the upper and lower jaws.

MAMMARY ARTERY. A chest wall artery that descends from the aorta and is commonly used for bypass grafts.

MAMMARY HYPERPLASIA. Increased size of the breast.

MAMMOGRAM. A set of x rays taken of the front and side of the breast; used to diagnose various abnormalities of the breast.

MAMMOGRAPHY. X-ray imaging of the breast that can often detect lesions in the tissue too small or too deep to be felt.

MAMMOPLASTY. Surgery performed to change the size or shape of breasts.

MAMMOTOME. A method for removing breast biopsies using suction to draw tissue into an opening in the side of a cylinder inserted into the breast tissue.

A rotating knife then cuts tissue samples from the rest of the breast; also known as a vacuum-assisted biopsy.

MANDALA. A design, usually circular, that appears in religion and art. In Buddhism and Hinduism, the mandala has religious ritual purposes and serves as a yantra (a geometric emblem or instrument of contemplation).

MANDIBLE. The lower jaw, a U–shaped bone attached to the skull at the temporomandibular joints.

MANIA. A mood disorder in which a person experiences prolonged elation or irritability characterized by overactivity that can lead to exhaustion and medical emergencies.

MANOMETER. A device used to measure fluid pressure.

MANOMETRY. Measurement of pressure.

MANTOUX TEST. A tuberculin skin test; also called the PPD (purified protein derivative) test.

MANTRA. A sacred word or formula repeated over and over to concentrate the mind.

MAO-B INHIBITORS. Inhibitors of the enzyme monoamine oxidase B. MAO-B helps break down dopamine; inhibiting it prolongs the action of dopamine in the brain.

MARASMUS. Severe malnutrition in children caused by a diet lacking in calories as well as protein. Marasmus may also be caused by disease and parasitic infection.

MARFAN SYNDROME. An inheritable disorder that affects the skeleton, joints, and blood vessels. Major indicators are excessively long arms and legs, lax joints, and vascular defects.

MARSUPIALIZATION. Cutting out a wedge of the cyst wall and putting in stitches so the cyst cannot reoccur.

MARTIAL ARTS. Group of diverse activities originating from ancient Asian fighting techniques.

MASOCHISM. Sexual arousal by having pain and/or humiliation inflicted upon oneself.

MAST CELLS. A type of immune system cell that is found in the lining of the nasal passages and eyelids, displays a type of antibody called immunoglobulin type E (IgE) on its cell surface, and participates in the allergic response by releasing histamine from intracellular granules.

MASTECTOMY, MODIFIED RADICAL. Total mastectomy with axillary lymph node dissection, but with preservation of the pectoral muscles.

MASTECTOMY, RADICAL. Removal of the breast, pectoral muscles, axillary lymph nodes, and associated skin and subcutaneous tissue.

MASTECTOMY, SIMPLE. Removal of only the breast tissue, nipple and a small portion of the overlying skin.

MASTOID BONE. The prominent bone behind the ear that projects from the temporal bone of the skull.

MASTOID PROCESS. The protrusions of bone behind the ears at the base of the skull.

MASTOIDITIS. An inflammation of the bone behind the ear (the mastoid bone) caused by an infection spreading from the middle ear to the cavity in the mastoid bone.

MASTOPEXY. Surgical procedure to lift up a breast. May be used on opposite breast to achieve symmetrical appearance with a reconstructed breast.

MATCH. How similar the HLA typing, out of a possible six antigens, is between a donor and a recipient.

MATERNAL. From one's mother.

MATERNAL BLOOD SCREENING. Maternal blood screening is normally done early in pregnancy to test for a variety of conditions. Abnormal amounts of certain proteins in a pregnant woman's blood raise the probability of fetal defects. Amniocentesis is recommended if such a probability occurs.

MATERNAL SERUM ANALYTE SCREENING. A medical procedure in which a pregnant woman's blood is drawn and analyzed for the levels of certain hormones and proteins. These levels can indicate whether there may be an abnormality in the unborn child. This test is not a definitive indicator of a problem and is followed by more specific testing such as amniocentesis or chorionic villus sampling.

MATERNAL UNIPARENTAL DISOMY. Chromosome abnormality in which both chromosomes in a pair are inherited from one's mother.

MATRIX. The tissue at the base of the nail, from which the nail grows.

MATURATION. The process by which stem cells transform from immature cells without a specific function into a particular type of blood cell with defined functions.

MAXILLA. The bone of the upper jaw, which serves as a foundation of the face and supports the orbits.

MCCUNE-ALBRIGHT SYNDROME (MCAS). A genetic syndrome characterized in girls by the development of ovarian cysts and puberty before the age of 8, together with abnormalities of bone structure and skin pigmentation.

MCH–1. Major histocompatibility complex proteins that protect cells from invasion.

MEAN CORPUSCULAR HEMOGLOBIN (MCH). A measurement of the average weight of hemoglobin in a red blood cell.

MEAN CORPUSCULAR HEMOGLOBIN CONCENTRATION (MCHC). The measurement of the average concentration of hemoglobin in a red blood cell.

MEAN CORPUSCULAR VOLUME (MCV). A measure of the average volume of a red blood cell.

MEASLES. An acute and highly contagious viral disease marked by distinct red spots followed by a rash that occurs primarily in children.

MEASLES ENCEPHALITIS. A serious complication of measles occurring in about one out of every 1,000 cases, causing headache, drowsiness, and vomiting seven to ten days after the rash appears. Seizures and coma can follow, which may lead to retardation and death.

MECHANICAL VALVE. An artificial device used to replace the patient's heart valve. They include three types: ball valve, disk valve, and bileaflet valve.

MECONIUM. A greenish fecal material that forms the first bowel movement of an infant.

MECONIUM ASPIRATION SYNDROME. Breathing in of meconium by a fetus or newborn, which can block air passages and interfere with lung expansion.

MEDIA. Substance that contains all the nutrients necessary for bacteria to grow in a culture.

MEDIAL WALL. The middle bone, or wall, of the eye's orbit. It is generally thicker than the roof and floor walls.

MEDIAN NERVE. A nerve that runs through the wrist and into the hand. It provides sensation and some movement to the hand, the thumb, the index finger, the middle finger, and half of the ring finger.

MEDIASTINOSCOPY. A procedure that allows the physician to see the organs in the mediastinal space using a thin, lighted, hollow tube (a mediastinoscope).

MEDIASTINUM. The area between the lungs, bounded by the spine, breastbone, and diaphragm.

MEDITATION. Technique of concentration for relaxing the mind and body.

MEDULLA OBLONGATA. The lowest section of the brainstem, located next to the spinal cord. The medulla is the site of important cardiac and respiratory regulatory centers.

MEDULLARY THYROID CANCER (MTC). A slow-growing tumor associated with multiple endocrine neoplasia.

MEFLOQUINE. An antimalarial drug that was developed by the United States Army in the early 1980s. Today, malaria resistance to this drug has become a problem in some parts of Asia (especially Thailand and Cambodia).

MEGACOLON. Abnormally large colon associated with some chronic intestine disorders.

MEGADOSE. A very large dose of a vitamin, taken by some people as a form of self-medication.

MEGAKARYOCYTE. A large bone marrow cell that is responsible for the production of platelets, which are active in blood clotting.

MEGALOBLAST. A large erythroblast (a red marrow cell that synthesizes hemoglobin).

MEIBOMIAN GLAND. Oil-producing glands in the eyelids that open near the eyelid margins.

MELANIN. A pigment that is responsible for the color of hair, skin, and eyes. Melanin also protects the body by absorbing ultraviolet light.

MELANOCYTE. An epidermal skin cell that produces melanin.

MELANOMA. A rapidly spreading and deadly form of cancer that usually occurs on the skin.

MELASMA. A dark mask-like discoloration that covers the cheeks and bridge of the nose. Also called "the mask of pregnancy."

MELATONIN. A hormone produced by the pineal gland that is associated with sleep, and that may be useful in the treatment of some sleep disorders.

MEMBRANE OXYGENATOR. The artificial lung that adds oxygen and removes carbon dioxide.

MENADIONE. A synthetic form of vitamin K. It is sometimes called vitamin K_3.

MENARCHE. The first menstrual period in a human female, considered the central event of puberty in girls.

MENDELIAN INHERITANCE. An inheritance pattern for autosomal gene pairs. The genetic trait displayed results from one parent's gene dominating over the gene inherited from the other parent.

MENGHINI NEEDLE. A special needle used to obtain a sample of liver tissue.

MÉNIÈRE'S DISEASE. An abnormality of the inner ear that causes dizziness, ringing in the ears, and hearing loss.

MENINGES (SINGULAR, MENINX). The membranes that cover the brain and spinal cord.

MENINGITIS. An infection or inflammation of the membranes or tissues that cover the brain and spinal cord, caused by bacteria or a virus.

MENOPAUSE. The end of a woman's menstrual periods when a woman no longer can conceive a child.

MENORRHAGIA. Excessively heavy menstrual flow with cycles of normal length. It is also called hypermenorrhea.

MENTAL RETARDATION. Significant impairment in intellectual function and adaptation in society. Usually associated an intelligence quotient (IQ) below 70.

MEQ/L. Abbreviation for milliequivalents per liter. Some medical test results are reported in mEq/L.

MERCURIC CHLORIDE; MERCURY(II) CHLORIDE; $HGCL_2$. A poisonous crystalline form of inorganic mercury that is used as a disinfectant and fungicide.

MERIDIAN. In traditional Chinese medicine, the channels that run beneath the skin through which the body's energy flows.

MESENTERIC ADENITIS. Inflammation of the lymph nodes that serve the small intestine. Has symptoms similar to appendicitis.

MESOSALPINX. A ligament connected to the fallopian tube.

MESOTHELIUM. A membrane/sac that protects the body's major internal organs and allows them freedom of movement (for example, lung contractions). The mesothelium is comprised of several regions, including the abdominal cavity (peritoneum), the chest cavity (pleura), and pericardium (heart).

METABOLIC. Refers to the chemical reactions in living things.

METABOLIC ACTIVITY. The sum of the chemical processes in the body that are necessary to maintain life.

METABOLIC BONE DISEASE. Weakening of bones due to a deficiency of certain minerals, especially calcium.

METABOLIC EQUIVALENT OF TASK (MET). The energy cost of a physical activity, measured as a multiple of the resting metabolic rate, which is defined as 3.5 milliliters of oxygen consumed per kilogram (kg) of body weight per minute, equivalent to 1 kilocalorie per kg per hour.

METABOLIC FUNCTION. Those processes necessary for the maintenance of a living organism.

METABOLIC PATHWAY. A sequence of chemical reactions that lead from some precursor to a product, where the product of each step in the series is the starting material for the next step.

METABOLIC SYNDROME. A group of risk factors for heart disease, diabetes, and stroke. It includes abdominal obesity, high blood pressure, high blood glucose levels, and low levels of high-density lipoprotein (HDL) cholesterol. The metabolic syndrome is sometimes called the insulin resistance syndrome.

METABOLISM. All the physical and chemical changes that occur in cells to allow growth and maintain body functions. These include processes that break down substances to yield energy and processes that build up other substances necessary for life.

METABOLITES. Substances produced by metabolism or by a metabolic process.

METACERCARIA (PLURAL, METACERCARIAE). The encysted stage of a fluke larva that produces infection in human beings.

METASTASIS (PLURAL, METASTASES). A tumor growth or deposit that has spread via lymph or blood to an area of the body remote from the primary tumor.

METASTASIZE. Spread of cells from the original site of the cancer to other parts of the body where secondary tumors are formed.

METASTATIC. The term used to describe a secondary cancer, or one that has spread from one area of the body to another.

METASTATIC CANCER. A cancer that has spread to an organ or tissue from a primary cancer located elsewhere in the body.

METHAMPHETAMINE (METH, METHADRINE, "SPEED"). A highly addictive medication that is widely abused as a stimulant.

METHEMOGLOBIN. A compound formed from hemoglobin by oxidation.

METHOTREXATE. A drug that interferes with cell growth and is used to treat rheumatoid arthritis as well as various types of cancer. Side effects may include mouth sores, digestive upsets, skin rashes, and hair loss.

METHYLATION TESTING. DNA testing that detects if a gene is active or imprinted.

METHYLENE BLUE. A dye that is used to stain the blood cells for the reticulocyte count.

METHYLMERCURY. Any of various toxic compounds containing the organic grouping CH_3Hg. These compounds occur as industrial byproducts and pesticide residues, accumulate in fish and other organisms—especially those high on the food chain, and are rapidly absorbed through the human intestine to cause neurological disorders such as Minamata disease.

METRONIDAZOLE. An anti-infective agent regarded as the best available drug for treating trichomoniasis. It is sold under the trade names Flagyl and MetroGel.

MIASM. In homeopathy, an inherited weakness or predisposition to disease.

MICROANGIOPATHIC. Pertaining to disorders of the small blood vessels.

MICROBE. A microorganism, especially a bacterium, that causes disease.

MICROCALCIFICATIONS. Tiny flecks that are too small to be felt. They are important markers of cancer that show up on ultrasound and mammogram.

MICROCEPHALY. An abnormally small head.

MICROCIRCULATION. The passage of blood in the smallest blood vessels of the body, such as the capillaries in the hand and fingers.

MICROCYTIC. A descriptive term applied to a smaller than normal red blood cell.

MICROEMBOLI. Small blot clots in the bloodstream.

MICROFILARIAE. The larvae and infective form of filarial worms.

MICROFLORA. The bacterial population in the intestine.

MICROKERATOME. A precision surgical instrument that can slice an extremely thin layer of tissue from the surface of the cornea.

MICRONUTRIENTS. Essential dietary elements that are needed only in very small quantities. Micronutrients are also known as trace elements. They include copper, zinc, selenium, iodine, magnesium, iron, cobalt, and chromium.

MICROORGANISMS. Microscopic organisms, such as bacteria, viruses, algae, and fungi.

MICROSPORIDA. A type of parasitic protozoa.

MICROSURGERY. Surgery on small body structures or cells performed with the aid of a microscope and other specialized instruments.

MICROTUBULES. Slender, elongated anatomical channels in worms.

MIDDLE EAR. The cavity or space between the eardrum and the inner ear. It includes the eardrum, the three little bones (hammer, anvil, and stirrup) that transmit sound to the inner ear, and the Eustachian tube, which connects the inner ear to the nasopharynx (the back of the nose).

MIGRAINE HEADACHE. An intense throbbing pain that occurs on one or both sides of the head. The headache is usually accompanied by other symptoms, such as nausea, vomiting, and aversion to light.

MIGRAINE NEURALGIA. A variant of migraine pain, also called cluster headache, in which severe attacks of pain affect the eye and forehead on one side of the face.

MILD COGNITIVE IMPAIRMENT (MCI). A transitional phase of memory loss in older people that precedes dementia or Alzheimer's disease.

MILIARY TUBERCULOSIS. The form of TB in which the bacillus spreads through all body tissues and organs, producing many thousands of tiny tubercular lesions. Miliary TB is often fatal unless promptly treated.

MILK-ALKALI SYNDROME. Elevated blood calcium levels and alkalosis caused by excessive intake of milk and alkalis. Usually occurs in the treatment of peptic ulcer.

MINERAL. An inorganic substance found in the earth that is necessary in small quantities for the body to maintain health. Examples: zinc, copper, iron.

MINERALIZATION. The process by which the body uses minerals to build bone structure.

MINIGRAFT OR MICROGRAFT. Transplantation of a small number of hair follicles, as few as one to three hairs, into a transplant site.

MINIMUM ERYTHEMA DOSE. The minimum amount of ultraviolet B (UVB) light that produces redness 24 hours after exposure. It is the starting dose for UVB light treatments.

MINIMUM PHOTOTOXIC DOSE. The dose of ultraviolet A (UVA) light that produces uniform redness 72 hours after ingesting a psoralen compound. It becomes the starting dose for PUVA (psoralen + UVA) treatment.

MIOTIC. A drug that causes pupils to contract.

MIRACIDIUM (PLURAL, MIRACIDIA). The free-swimming larval form in the life cycle of the liver fluke.

MISCARRIAGE. The spontaneous end of a pregnancy before the twentieth week. The death of the fetus is a common cause of miscarriage.

MISPROSTOL. A drug used in combination with mifepristone to cause uterine contractions that expel the contents of the uterus.

MITE. An insect parasite belonging to the order Acarina.

MITOCHONDRIA. Spherical or rod-shaped parts of the cell. Mitochondria contain genetic material (DNA and RNA) and are responsible for converting food to energy.

MITRAL STENOSIS. Narrowing or constricting of the mitral valve, which separates the left atrium from the left ventricle.

MITRAL VALVE. The heart valve that prevents blood from flowing backwards from the left ventricle into the left atrium. Also known as bicuspid valve.

MITRAL VALVE LEAFLETS. The mitral valve is made up of two valve leaflets (the anteromedial leaflet and the posterolateral leaflet) and a ring around the valve, known as the mitral valve annulus. The orientation of the two leaflets resembles a bishop's miter, which is where the valve received its name.

MITRAL VALVE PROLAPSE. A heart defect in which one of the valves of the heart (which normally controls blood flow) becomes floppy. Mitral valve prolapse may be detected as a heart murmur but there are usually no symptoms.

MIXED MANIA. A mental state in which symptoms of both depression and mania occur simultaneously.

MOBILIZATION. Making movable; restoring the power of motion in a joint; movement that increases joint mobility.

MODALITIES. The factors and circumstances that cause a patient's symptoms to improve or worsen.

MOHS' MICROGRAPHIC SURGERY. A surgical technique in which successive rings of skin tissue are removed and examined under a microscope to ensure that no cancer is left.

MOLARS. The teeth behind the primary canines or permanent premolars, with large crowns and broad chewing surfaces for grinding food.

MOLLUSCUM CONTAGIOSUM. A disease of the skin and mucuous membranes, caused by a poxvirus and found all over the world.

MONOAMINE OXIDASE INHIBITOR (MAOI). An older class of antidepressants.

MONOCHORIONIC TWINS. Twins that share a single placenta.

MONOCLONAL. Identical cells or proteins; cells (clones) derived from a single, genetically distinct cell, or proteins produced by these cells.

MONOCLONAL ANTIBODY. A protein substance that is produced in the laboratory by a single population of cells; used in cancer immunotherapy treatment.

MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE (MGUS). Common condition in which M-protein is present, but there are no tumors or other symptoms of disease.

MONOCYTE. White blood cell that increases during a variety of conditions including severe infections. It removes debris and microorganisms by the cellular process phagocytosis.

MONONUCLEAR PHAGOCYTE. A type of cell of the human immune system that ingests bacteria, viruses, and other foreign matter, thus removing potentially harmful substances from the bloodstream. These substances are usually then digested within the phagocyte.

MONONUCLEOSIS. An infection that causes swelling of lymph nodes, spleen, and liver, usually accompanied by extremely sore throat, fever, headache, and intense long-lasting fatigue.

MONOSACCHARIDE. The simplest form of sugar. Monosaccharides combine to form disaccharides and such complex carbohydrates as starch and cellulose.

MONOUNSATURATED FAT. Fats that contain one double or triple bond per molecule; examples include canola oil and olive oil.

MONS PUBIS. The fatty tissue over the area where the pubic bones meet.

MONSEL'S SOLUTION. A solution used to stop bleeding.

MONTELUKAST (SINGULAIR). An inhibitor that prevents leukotrienes from binding to cell receptors; taken over time, montelukast can reduce or prevent symptoms of asthma and allergies.

MOOD DISORDER. A group of mental disorders involving a disturbance of mood, along with either a full or partial excessively happy (manic) or extremely sad (depressive) syndrome not caused by any other physical or mental disorder. Mood refers to a prolonged emotion.

MORBIDITY. Morbidity refers to an illness or disease condition. In statistics it refers to the rate at which a disease occurs.

MORBIDLY OBESE. Definition of a person who is 100 lb (45 kg) or more than 50% overweight and has a body mass index above 40.

MORO REFLEX. A reflex startle reaction in infants: the arms and legs move away from the body and to the side and are then drawn together.

MORPHEA. The most common form of localized scleroderma.

MORPHINE. Morphine is the naturally occurring opioid in the opium poppy, *Papaver somniferum*. It is a powerful narcotic analgesic, and its primary clinical use is in the management of moderately severe to severe pain. After heroin, morphine has the greatest potential for addiction of all narcotic analgesics.

MORPHOLOGY. Literally, the study of form. In medicine, morphology refers to the size, shape, and structure rather than the function of a given organ.

MORTALITY. Mortality means death. In statistics it refers to the rate at which death occurs in a population for a particular disease condition.

MOSAIC. A term referring to a genetic situation in which an individual's cells do not have the exact same composition of chromosomes—for example, in Down syndrome, some of the individual's cells may have a normal 46 chromosomes, while other cells have an abnormal 47 chromosomes.

MOSAICISM. A genetic condition resulting from a mutation, crossing over, or nondisjunction of chromosomes during cell division, causing a variation in the number of chromosomes in the cells.

MOTHER TINCTURE. The first stage in the preparation of a homeopathic remedy, made by soaking a plant, animal, or mineral product in a solution of alcohol.

MOTILITY. The movement or capacity for movement of an organism or body organ.

MOTION SICKNESS. Also called kinetosis; nausea and possibly vomiting induced by motion, such as travel by car, boat, or plane.

MOTOR. Of or pertaining to motion, the body apparatus involved in movement, or the brain functions that direct purposeful activity.

MOTOR NERVE. Motor or efferent nerve cells carry impulses from the brain to muscle or organ tissue.

MOTOR NEURON. Nerve cells within the central nervous system that carry nerve impulses controlling muscle movement.

MOTOR SKILL LEARNING. Memory system associated with physical movement and activity. For example, learning to swim is initially difficult, but once an efficient stroke is learned, it requires little conscious effort.

MOTOR SKILLS. Controlled movement of muscle groups. Fine motor skills involve tasks that require dexterity of small muscles, such as buttoning a shirt. Tasks such as walking or throwing a ball involve the use of gross motor skills.

MOTOR UNIT ACTION POTENTIALS. Spikes of electrical activity recorded during an EMG that reflect the number of motor units (motor neurons and the muscle fibers they transmit signals to) activated when the patient voluntarily contracts a muscle.

MOURNING. The public expression of bereavement; it may include funerals and other rituals, special clothing, and symbolic gestures.

MOUSSE OIL. Crude oil that has emulsified or weathered, mixed with dispersants, water, and marine material to form a spongy, light brown, mousse-like material.

MOXIBUSTION. An acupuncture technique that burns the herb moxa or mugwort.

MUCIN. A protein in saliva that combines with sugars in the mouth to form plaque.

MUCINOUS (COLLOID) CARCINOMA. A type of cancer that accounts for 1% to 2% of breast cancers. Resembles medullary carcinoma in ultrasound and mammogram, but usually affects older women.

MUCOCILIARY ESCALATOR. The coordinated action of tiny projections on the surfaces of cells lining the respiratory tract, which moves mucus up and out of the lungs.

MUCOCUTANEOUS LYMPH NODE SYNDROME (MLNS). Another name for Kawasaki syndrome. The name comes from the key symptoms of the disease, which involve the mucous membranes of the mouth and throat, the skin, and the lymph nodes.

MUCOLYTIC. An agent that dissolves or destroys mucin, the chief component of mucus.

MUCOPOLYSACCHARIDE. A complex molecule made of smaller sugar molecules strung together to form a chain. Found in mucous secretions and intercellular spaces.

MUCOSA. The mucous membrane, or the thin layer that lines body cavities and passages.

MUCOSAL. Refers to tissues that produce mucus, such as the digestive, genital, and urinary tracts.

MUCOUS MEMBRANES. The moist coverings that line the mouth, nose, intestines, and other internal organs.

MUCUS. Thick fluid produced by the moist membranes that line many body cavities and structures.

MULTIDRUG–RESISTANT ORGANISMS (MDROS). Bacteria that are resistant to one or more classes of antimicrobial agents and usually are resistant to all but one or two commercially available antimicrobial agents.

MULTI-FETAL PREGNANCY. A pregnancy of two or more fetuses.

MULTIFOCAL. Having many focal points; occuring at multiple sites.

MULTI-INFARCT DEMENTIA. Dementia caused by damage to brain tissue resulting from a series of blood clots or clogs in the blood vessels. It is also called vascular dementia.

MULTINODULAR GOITER. A condition in which benign lumps of tissue (nodules) form within the thyroid gland and cause it to secrete too much thyroid hormone. It is also called Plummer's disease.

MULTIPLE CHEMICAL SENSITIVITY. A condition characterized by severe and crippling allergic reactions to commonly used substances, particularly chemicals. Also called environmental illness.

MULTIPLE ENDOCRINE NEOPLASIA. Abnormal tissue growth on one or more of the endocrine (hormone-secreting) glands.

MULTIPLE ENDOCRINE NEOPLASIA TYPE 1 (MEN-1). An inherited condition marked by multiple malignancies of the pituitary gland, parathyroid gland, and islet cells of the pancreas. About half of MEN-1 patients with pancreatic islet cell tumors will have gastrinomas, gastrin-producing tumors that lead to ulcer disease.

MULTIPLE MYELOMA. Cancer of the plasma cells.

MULTIPLE PERSONALITY DISORDER (MPD). An older term for dissociative identity disorder (DID).

MULTIPLE SCLEROSIS. A degenerative nervous system disorder in which the protective covering of the nerves in the brain are damaged, leading to tremor and paralysis.

MULTITASKING. Performing multiple duties or taking on multiple responsibilities and roles simultaneously.

MUMPS. An acute and highly contagious viral illness that usually occurs in childhood.

MUNCHAUSEN BY PROXY. A factitious diagnosis in children produced by a parent or other caregiver.

MUNCHAUSEN SYNDROME. A factitious self-diagnosis in which the patient's symptoms are dramatized and exaggerated.

MURMUR. An abnormal heart sound that can reflect a valve dysfunction.

MUSCLE DYSMORPHIA. A subtype of body dysmorphic disorder, described as excessive preoccupation with muscularity and body building to the point of interference with social, educational, or occupational functioning.

MUSCLE TONE. Also termed tonus; the normal state of balanced tension in the tissues of the body, especially the muscles.

MUSCULAR DYSTROPHY. A group of inherited diseases characterized by progressive wasting of the muscles.

MUTATE. Undergo a spontaneous change in the makeup of genes or chromosomes.

MUTATION. A permanent change in the genetic material that may alter a trait or characteristic of an individual, or manifest as disease, and can be transmitted to offspring.

MUTISM. The inability or refusal to speak.

MYALGIA. Muscular pain or tenderness, typically of a diffuse and/or nonspecific nature.

MYALGIC ENCEPHALOMYELITIS. An older name for chronic fatigue syndrome; encephalomyelitis refers to inflammation of the brain and spinal cord.

MYASTHENIA GRAVIS. A muscle weakness that occurs because the body makes antibodies to the natural chemical that facilitates transmission of impulses between the nerve and the muscle.

MYCOBACTERIA. A group of bacteria that includes *Mycobacterium tuberculosis*, the bacterium that causes tuberculosis, and other forms that cause related illnesses.

MYCOPLASMA. A type of free-living microorganism that has no cell wall. Mycoplasmas cause some varieties of pneumonia and urinary tract infections that stimulate the body to produce cold agglutinins.

MYCOPLASMA PNEUMONIA. An incomplete bacterium that infects the lung.

MYCOSIS FUNGOIDES. The most common type of cutaneous T-cell lymphoma. This low-grade lymphoma primarily affects the skin. Generally, it has a slow course and often remains confined to the skin. In about 10% of cases, it can progress to the lymph nodes and internal organs.

MYDRIATIC. Causing dilation or widening of the pupil of the eye.

MYELIN. A protective cover that surrounds nerve cells and helps to increase the speed by which information travels along the nerve; also referred to as myelin sheath.

MYELODYSPLASIA. Also called myelodysplastic syndrome, it is a condition in which the bone marrow does not function normally and can affect the various types of blood cells produced in the bone marrow. Often referred to as a preleukemia and may progress and become acute leukemia.

MYELOFIBROSIS. An anemic condition in which bone marrow cells are abnormal or defective and become fibrotic.

MYELOGRAM. A special type of x-ray study of the spinal cord, made after a contrast medium has been injected into the space surrounding the cord.

MYELOGRAPHY. An imaging procedure involving the injection of a radioactive dye into the fluid surrounding the spine. A myelography can be used to detect herniated disks, nerve root damage, and other problems affecting the cervical spine.

MYELOMA. A tumor of plasma cells that originates in bone marrow and usually spreads to more than one bone.

MYELOMENINGOCELES (MMC). A protrusion in the vertebral column containing spinal cord and meninges.

MYELOPATHY. A disorder in which the tissue of the spinal cord is diseased or damaged.

MYELOPROLIFERATIVE DISORDER. A disorder in which the bone marrow produces too many cells too rapidly.

MYELOSUPPRESSIVE THERAPY. Any form of treatment that is aimed at slowing down the rate of blood cell production.

MYOCARDIAL INFARCTION. Commonly known as a heart attack, a myocardial infarction is an episode in which some of the heart's blood supply is severely cut off or restricted, causing the heart muscle to suffer and die from lack of oxygen.

MYOCARDITIS. Inflammation of the heart tissue.

MYOCARDIUM. The medical term for the specialized involuntary muscle tissue found in the walls of the heart.

MYOCLONIC. A rapid, involuntary muscle contraction, particularly near the eye.

MYOCLONUS. Involuntary contractions of a muscle or group of muscles.

MYOFASCIAL. The fibrous tissue that encloses and separates layers of muscles.

MYOGLOBIN. A protein that holds oxygen in heart and skeletal muscle. It rises after damage to either of these muscle types.

MYOGLOBINURIA. Reddish urine caused by excretion of myoglobin, a breakdown product of muscle.

MYOMA. Benign (noncancerous) tumors of the uterus.

MYONECROSIS. The destruction or death of muscle tissue.

MYOPATHY. A disorder that causes weakening of muscles.

MYOPIA. A vision problem in which distant objects appear blurry. Myopia results when the cornea is too steep or the eye is too long and the light doesn't focus properly on the retina. People who are myopic or

nearsighted can usually see near objects clearly, but not far objects.

MYOTONIC DYSTROPHY. A form of muscular dystrophy, also known as Steinert's condition, characterized by delay in the ability to relax muscles after forceful contraction, wasting of muscles, and other abnormalities.

MYRINGOTOMY. Surgical cutting of the eardrum to allow fluid to escape from the middle ear.

MYXEDEMA. Hypothyroidism, characterized by thick, puffy features; an enlarged tongue; and lack of emotion.

N

NAIL BED. The layer of tissue underneath the nail.

NALTREXONE. A medication originally developed to treat addiction to heroin or morphine that is also used to treat alcoholism. It works by reducing the craving for alcohol rather than by producing vomiting or other unpleasant reactions.

NANOMETER. A measurement of length equal to 10^{-9} meters, or one billionth of a meter. It is used as a unit of measurement for light waves.

NARCOLEPSY. A lifelong sleep disorder marked by four symptoms: sudden brief sleep attacks, cataplexy, temporary paralysis, and hallucinations. The hallucinations are associated with falling asleep or the transition from sleeping to waking.

NARCOTIC. A drug derived from opium or compounds similar to opium. Such drugs are potent pain relievers and can affect mood and behavior. Long-term use of narcotics can lead to dependence and tolerance.

NASAL POLYPS. Drop-shaped overgrowths of the nasal membranes.

NASAL SCRAPING. Pathological material obtained for clinical study by scratching the inner surface of the nose with a clinical instrument.

NASAL SEPTUM. The membrane that separates the nostrils.

NASOGASTRIC TUBE. A tube placed through the nose into the stomach.

NASOLACRIMAL DUCT. A channel that transmits tears from the lacrimal sac to the nose.

NASOPHARYNGEAL. Referring to the passage connecting the nasal cavity behind the nose to the top of the throat behind the soft palate.

NASOPHARYNGOSCOPY. A diagnostic procedure that examines the nasal passageways and pharynx with an instrument outfitted with an optical system.

NASOPHARYNX. The passage that connects the nasal cavity to the top of the throat.

NATURAL KILLER (NK) CELL. A lymphocyte that acts as a primary immune defense against infection.

NATUROPATHIC PHYSICIANS. Physicians specializing in the treatment of disease using a variety of natural methods and plant-based medicines.

NAUSEA. Stomach distress characterized by a distaste for food and the urge to vomit.

NEARSIGHTEDNESS. A condition in which one or both eyes cannot focus normally, causing objects at a distance to appear blurred and indistinct. Also called myopia.

NEBULIZER. A device that turns liquid forms of medicine into a fine spray that can be inhaled.

NECROSIS. The death of cells, a portion of tissue, or a portion of an organ due to permanent damage of some sort, such as a lack of oxygen supply to the tissues.

NECROTIZING ENTEROCOLITIS (NEC). A condition in which part of the intestines are destroyed as a result of bacterial infection.

NECROTIZING FASCIITIS. A destructive infection which follows severe cellulitis and involves the deep skin and underlying tissues.

NECROTIZING PNEUMONIA. Pneumonia that causes the death of lung tissue. It often precedes the development of lung abscess.

NEEDLE BIOPSY. The procedure of using a large hollow needle to obtain a sample of intact tissue.

NEGATIVE SYMPTOMS. Symptoms of schizophrenia characterized by the absence or elimination of certain behaviors. DSM–IV specifies three negative symptoms: affective flattening, poverty of speech, and loss of will or initiative.

NEGATIVISM. Behavior characterized by resistance, opposition, and refusal to cooperate with requests, even the most reasonable ones.

NEISSERIA GONORRHOEAE. The bacterium that causes gonorrhea.

NEMATODE. A type of roundworm with a long, unsegmented body, usually parasitic on animals or plants.

NEOADJUVANT THERAPY. Radiation therapy or chemotherapy used to shrink a tumor before surgical removal of the tumor.

NEONATAL. Referring to the period shortly after birth.

NEONATAL JAUNDICE. A disorder in newborns where the liver is too premature to conjugate bilirubin, which builds up in the blood.

NEONATE. A term referring to the newborn infant, from birth until one month of age.

NEONATOLOGIST. A physician who specializes in problems of newborn infants.

NEOPLASIA. Abnormal growth of cells, which may lead to a neoplasm, or tumor.

NEOPLASM. An uncontrolled growth of new tissue (a tumor).

NEOVASCULARIZATION. Abnormal or excessive formation of blood vessels as in some retinal disorders.

NEPHRECTOMY. A medical procedure in which the kidney is surgically removed.

NEPHRITIS. Inflammation of the kidneys.

NEPHROLOGIST. A doctor who specializes in the diseases and disorders of the kidneys.

NEPHRON. The basic structural unit of the kidney, responsible for regulating the concentration of water and soluble chemicals in the blood by filtering the blood, reabsorbing the compounds needed by the body, and excreting the rest in the urine. Each kidney in humans contains between 800,000 and one million nephrons.

NEPHROSCOPE. An instrument made of a light source in a tube. The tube is inserted into the kidney through an incision in the back and used to locate kidney stones. The stones are broken up with high frequency sound waves and removed by suction through the scope.

NEPHROSIS. Any degenerative disease of the kidney (not to be confused with nephritis, an inflammation of the kidney due to bacteria).

NEPHROTIC SYNDROME. A condition characterized by water retention, little or no protein in urine, and high blood cholesterol.

NEPHROTOXIC. Toxic, or damaging, to the kidney.

NEPHROTOXIN. Substance that is poisonous to the kidneys.

NERVE BIOPSY. A medical test in which a small portion of a damaged nerve is surgically removed and examined under a microscope.

NERVE CONDUCTION. The speed and strength of a signal being transmitted by nerve cells.

NERVE CONDUCTION TESTING; NERVE CONDUCTION VELOCITY TEST. Procedure that measures the speed at which impulses move through the nerves after electrical stimulation.

NERVE GROWTH FACTOR. A protein resembling insulin that affects growth and maintenance of nerve cells.

NERVOUS SYSTEM. The complete network of the body's nerves, sense organs, and brain.

NERVOUS TIC. A repetitive, involuntary action, such as the twitching of a muscle or repeated blinking.

NEUCHAL TRANSLUCENCY. A pocket of fluid at the back of an embryo's neck visible via ultrasound that, when thickened, may indicate the infant will be born with a congenital heart defect.

NEURAL TUBE DEFECTS (NTDS). A group of birth defects that affect the brain and spinal cord.

NEURALGIA. Pain extending along one or more nerves.

NEURALLY MEDIATED HYPOTENSION. A rapid fall in blood pressure that causes dizziness, blurred vision, and fainting, often followed by prolonged fatigue.

NEURASTHENIA. A term coined in the late nineteenth century to refer to a condition of chronic mental and physical weakness and fatigue.

NEURITIS. An inflammation of the nerves.

NEUROBLAST. An embryonic nerve cell that differentiates into a neuron.

NEUROBLAST CELLS. Cells produced by the fetus that mature into nerve cells and adrenal medulla cells.

NEUROBLASTOMA. Neuroblastoma is a tumor of the adrenal glands or sympathetic nervous system. Neuroblastomas can range from being relatively harmless to highly malignant.

NEUROCYSTICERCOSIS. Parasitic infection caused by the presence of immature tapeworm larvae within the central nervous system.

NEURODEGENERATIVE. Relating to degeneration of nerve tissues.

NEURODEGENERATIVE DISEASE. A disease in which the nervous system progressively and irreversibly deteriorates.

NEURODERMATITIS. An itchy skin disease (also called lichen simplex chronicus) found in nervous, anxious people.

NEUROFIBRILLARY TANGLES. Accumulations of twisted protein fragments inside nerve cells in the brain that are diagnostic of Alzheimer's disease.

NEUROFIBROMA. A soft tumor usually located on a nerve.

NEUROFIBROMATOSIS. A rare hereditary disease that involves the growth of lesions that may affect the spinal cord.

NEUROFIBROMATOSIS TYPE 2 (NF2). A hereditary condition associated with an increased risk of bilateral acoustic neuromas, other nerve cell tumors, and cataracts.

NEUROGENIC. Caused by nerves; originating in the nerves.

NEUROLEPTICS. Antipsychotic drugs, including major tranquilizers, used in the treatment of psychoses like schizophrenia.

NEUROLOGIC. Pertaining to the nervous system.

NEUROLOGICAL CONDITIONS. A condition that has its origin in some part of the patient's nervous system.

NEUROLOGICAL SYSTEM. The tissue that initiates and transmits nerve impulses, including the brain, spinal cord, and nerves.

NEUROLOGIST. A doctor who specializes in disorders of the brain and central nervous system.

NEUROMUSCULAR. Relating to nerves and muscles or their interaction.

NEUROMUSCULAR JUNCTION. The site at which nerve impulses are transmitted to muscles.

NEURON. A unique type of cell found in the brain and body that is specialized to process and transmit information.

NEUROPATHY. A condition affecting the nerves supplying the arms and legs. Typically, the feet and hands are involved first. If sensory nerves are involved, numbness, tingling, and pain are prominent, and if motor nerves are involved, the patient experiences weakness.

NEUROPROTECTIVE. Conveying some form of protection to the nervous system from injury.

NEUROPSYCHOLOGICAL TEST. A test or assessment given to diagnose or evaluate a brain disorder, disease, or injury.

NEUROPSYCHOLOGIST. A clinical psychologist who specializes in assessing psychological status caused by a brain disorder.

NEUROSYPHILIS. Syphilis of the central nervous system.

NEUROTIC. Behavior characterized by neurosis, mental functional orders with symptoms such as anxiety, depression, compulsions, and phobias.

NEUROTOXIN. A substance that damages, destroys, or impairs the functioning of nerve tissue.

NEUROTRANSMISSION. When a neurotransmitter, or chemical agent released by a particular brain cell, travels across the synapse to act on the target cell to either inhibit or excite it.

NEUROTRANSMITTER. One of a group of chemicals secreted by a nerve cell (neuron) to carry a chemical message to another nerve cell, often as a way of transmitting a nerve impulse. Examples of neurotransmitters include acetylcholine, dopamine, serotonin, and norepinephrine.

NEUTROPHIL. The primary type of white blood cell involved in inflammation. Neutrophils are a type of granulocyte, also known as a polymorphonuclear leukocyte.

NEVUS (PLURAL, NEVI). The medical term for any anomaly of the skin that is present at birth, including moles and birthmarks.

NIACINAMIDE. A form of niacin that is usually used as a dietary supplement for people with insufficient niacin.

NICOTINE. A colorless, oily chemical found in tobacco that makes people physically dependent on smoking. It is poisonous in large doses.

NICOTINE REPLACEMENT THERAPY. A method of weaning a smoker away from the habit by giving the smoker smaller and smaller doses of nicotine over time.

NIGHT GUARD. A removable, custom-fitted plastic appliance that fits between the upper and lower teeth to prevent them from grinding against each other.

NIMODIPINE (NIMOTOP). A calcium-channel blocker; a drug that relaxes arterial smooth muscle by slowing the movement of calcium across cell walls.

NIT. The egg sac laid by adult female lice.

NITROGEN NARCOSIS. Also called "rapture of the deep," the condition is caused by increased nitrogen pressure at depth and is characterized by symptoms similar to alcohol intoxication.

NITROPRUSSIDE. A compound that is used in laboratory tests to identify large amounts of cystine in urine samples.

NITROUS OXIDE. A colorless, sweet-smelling gas used by dentists for mild anesthesia. It is sometimes called laughing gas because it makes some patients feel giddy or silly.

NOCICEPTOR. A nerve cell that is capable of sensing pain and transmitting a pain signal.

NOCTURIA. Excessive need to urinate at night.

NOCTURNAL ENURESIS. The medical term for bedwetting.

NOCTURNAL MYOCLONUS. A disorder in which the patient is awakened repeatedly during the night by cramps or twitches in the calf muscles. Nocturnal myoclonus is sometimes called periodic limb movement disorder (PLMD).

NODULAR GOITER. An enlargement of the thyroid (goiter) caused when groups of cells collect to form nodules.

NODULES. A small mass of tissue in the form of a protuberance or a knot that is solid and can be detected by touch.

NONDISJUNCTION. Non-separation of a chromosome pair, during either meiosis or mitosis.

NON-HODGKIN'S LYMPHOMA. Cancer that originates in the lymphatic system and typically spreads throughout the body.

NONINVASIVE. A procedure that does not penetrate the body.

NON-IONIZING RADIATION. Rays of energy that move in long, slow wave patterns and do not penetrate cells.

NONMELANOMA SKIN CANCER. A squamous cell carcinoma or basal cell carcinoma.

NON-MYELOABLATIVE ALLOGENEIC BONE MARROW TRANSPLANT. Also called "mini" bone marrow transplants, this type of transplant involves receiving low-doses of chemotherapy and radiation therapy, followed by the infusion of a donor's bone marrow or peripheral stem cells. The goal is to suppress the patient's own bone marrow to allow the donor's cells to engraft.

NON-NUCLEOSIDE REVERSE TRANSCRIPTASE INHIBITORS. A class of antiretroviral drugs that work by inhibiting the reverse transcriptase enzyme necessary for HIV replication.

NONOXYNOL-9. The chemical name of the organic compound most commonly used in contraceptive creams, foams, and jellies. It was also used in the manufacture of spermicide-treated condoms until 2005, but the use of such condoms is now discouraged.

NONPALPABLE. Cannot be felt by hand.

NONPHARMACOLOGICAL. Referring to therapy that does not involve drugs.

NONPROLIFERATIVE RETINOPATHY. Retinopathy without the growth of new blood vessels.

NON-RAPID EYE MOVEMENT (NREM) SLEEP. A type of sleep that differs from rapid eye movement (REM) sleep. The four stages of NREM sleep account for 75%–80% of total sleeping time.

NONSPHEROCYTIC. Not sphere-shaped.

NONSPHEROCYTIC HEMOLYTIC ANEMIA. Anemia caused by variably shaped red blood cells that burst, or hemolyze, easily.

NONSTEROIDAL. Not containing steroids or cortisone.

NONSTEROIDAL ANTI-INFLAMMATORY DRUGS (NSAIDS). A class of drugs that is used to relieve pain and symptoms of inflammation, such as ibuprofen and aspirin.

NON-STRESS TEST. A record of the fetal heart rate in the absence of contractions (stress).

NONVERBAL LEARNING DISABILITY (NLD). A learning disability syndrome identified in 1989 that may overlap with some of the symptoms of Asperger syndrome.

NOREPINEPHRINE. A hormone released by nerve cells and the adrenal medulla that causes constriction of blood vessels. Norepinephrine also functions as a neurotransmitter.

NORMAL FLORA. The mixture of bacteria normally found at specific body sites.

NORMAL WEIGHT. A BMI of between 18.5 and 24.9.

NORMOCHROMIC. A descriptive term applied to a red blood cell with a normal concentration of hemoglobin.

NORMOCYTIC. A descriptive term applied to a red blood cell of normal size.

NORMS. Normative or mean score for a particular age group.

NOSOCOMIAL. Contracted in a hospital; nosocomial infections are infections acquired by a patient while in the hospital.

NOSODE. A homeopathic remedy made from microbes, pus, or other disease material.

NOTCHING. A deformity of the surface of the ribs that is often associated with coarctation of the aorta.

NPO. A term that means "nothing by mouth." NPO refers to the time after which a patient is not allowed to eat or drink prior to a procedure or treatment.

NUCHAL CORD. The term used when the umbilical cord is looped around the fetus's neck in utero.

NUCHAL CYSTS. Small cysts in the fetus's neck that present in 1% of pregnancies.

NUCLEAR FAMILY. The basic family unit, consisting of father, mother, and their biological children.

NUCLEAR MEDICINE. A branch of medicine that makes use of radioisotopes (also called radionuclides) to evaluate the rate of radioactive decay in diagnosing and treating various diseases.

NUCLEAR SCANNING. Use of injected radioactive elements to analyze blood flow.

NUCLEIC ACID AMPLIFICATION TEST (NAAT). A screening test for gonorrhea that detects bacterial DNA in a urine sample or cervical swab.

NUCLEIC ACIDS. The cellular molecules DNA and RNA that act as coded instructions for the production of proteins and are copied for transmission of inherited traits.

NUCLEOSIDE ANALOGUES. The first group of effective antiretroviral medications. They work by interfering with the AIDS virus's synthesis of DNA.

NUCLEOTIDE. Any of a group of organic molecules that link together to form the building blocks of DNA or RNA.

NUCLEUS PULPOSUS (NP). An elastic, pulpy mass in the center of each vertebral disk.

NULLIPARITY. The condition of being nulliparous, or not bearing offspring.

NUMBNESS. Loss of feeling or sensation.

NUTRIENT. A food substance that provides energy or is necessary for growth and repair. Examples of nutrients are vitamins, minerals, carbohydrates, fats, and proteins.

NYMPH. The immature louse that hatches from the nit.

NYSTAGMUS. An involuntary back-and-forth movement of the eyes that is often found in albinism.

O

OBESITY. Excessive weight due to accumulation of fat, usually defined as a body mass index (BMI) of 30 or above or body weight greater than 30% above normal on standard height-weight tables.

OBSESSION. A repetitive or persistent thought, idea, or impulse that is perceived as inappropriate and distressing.

OBSESSIVE-COMPULSIVE DISORDER. An anxiety disorder in which people cannot prevent themselves from dwelling on unwanted thoughts, acting on urges, or performing repetitious rituals, such as washing their hands or checking to make sure they turned off the lights.

OBSTRUCTION. A blockage that prevents movement.

OBSTRUCTIVE SLEEP APNEA (OSA). A potentially life-threatening condition characterized by episodes of breathing cessation during sleep alternating with snoring or disordered breathing. The low levels of oxygen in the blood of patients with OSA may eventually cause heart problems or stroke.

OCCIPITAL NEURALGIA. Pain on one side of the back of the head caused by entrapment or pinching of an occipital nerve.

OCCLUSION. The way upper and lower teeth fit together during biting and chewing.

OCCLUSION THERAPY. A type of treatment for amblyopia in which the good eye is patched for a period of time. This forces the weaker eye to be used.

OCCLUSIVE. Closing off; blocking.

OCCULT. Not visible or easily detected.

OCCULT BLOOD. Presence of blood that cannot be seen with the naked eye.

OCHRONOSIS. People with this rare hereditary condition tend to develop arthritis in adulthood.

OCULAR FUNDUS. The part of the eye opposite the pupil.

OCULAR LARVA MIGRANS (OLM). A syndrome associated with toxocariasis, in which the eye is invaded by migrating larvae.

OCULAR MELANOMA. A malignant tumor that arises within the structures of the eye. It is the most common eye tumor in adults.

OCULAR NEOVASCULARIZATION. Abnormal or excessive formation of blood vessels in the eye.

OCULOPHARYNGEAL MUSCULAR DYSTROPHY (OPMD). Form of muscular dystrophy affecting adults of both sexes, and causing weakness in the eye muscles and throat.

ODYNOPHAGIA. Pain felt when swallowing.

OFF-LABEL USE. The use of a prescription medication to treat conditions outside the indications approved by the U.S. Food and Drug Administration (FDA). It is legal for physicians to administer drugs for off-label uses, but it is not legal for pharmaceutical companies to advertise drugs for off-label uses.

OINTMENT. A thick substance that contains medicine and is meant to be spread on the skin, or if an ophthalmic ointment, in the eye.

OMEGA-3 FATTY ACIDS. A class of fatty acids that lowers the level of cholesterol in the blood. Omega-3 fatty acids are also essential for the growth and development of the brain and nerve tissue.

OMPHALOCELE. A congenital hernia in which a small portion of the fetal abdominal contents, covered by a membrane sac, protrudes into the base of the umbilical cord.

ONCHOCERCIASIS. Parasitic infestation caused by filamentous worms of the genus Onchocerca, especially *Onchocerca volvulus*, that is found in tropical America and is transmitted by several types of blackflies.

ONCOGENE. A gene that causes normal cell growth, but if mutated or expressed at high levels, encourages normal cells to change into cancerous cells.

ONCOLOGIST. A doctor who specializes in the treatment of cancer.

ONYCHOLYSIS. The separation of a nail from its underlying bed. Onycholysis is a common symptom of candidal infections of the nail or of exposure to harsh chemicals and detergents.

OOCYST. The egg form of the toxoplasmosis organism.

OOPHORECTOMY. Surgical removal of the ovaries; often performed laparoscopically.

OPACITY. An opaque spot in a normally transparent structure, such as the lens of the eye.

OPEN BITE. A malocclusion in which some teeth do not meet the opposing teeth.

OPHTHALMIA. Inflammation of the eye, usually severe and affecting the conjunctiva.

OPHTHALMIA NEONATORUM. The medical term for conjunctivitis in newborns.

OPHTHALMIC. Pertaining to the eye.

OPHTHALMIC ARTERY. The artery supplying the eye and adjacent structures with blood.

OPHTHALMOLOGIST. A physician specializing in the medical and surgical treatment of eye disorders.

OPHTHALMOLOGY. The branch of medicine that deals with the diagnosis and treatment of eye disorders.

OPHTHALMOSCOPE. An instrument routinely used by ophthalmologists to examine the interior of the eye. It consists of a small light, a mirror, and lenses of differing powers that magnify.

OPIATE. A drug containing or derived from opium—such as codeine, morphine, and heroin—that alleviates pain and induces sleep.

OPIATE BLOCKERS. A type of drug that blocks the effects of natural opiates in the system. This makes some people, including some people with autism, appear more responsive to their environment.

OPIOID. Any morphine-like synthetic narcotic that produces the same effects as drugs derived from the opium poppy (opiates), such as pain relief, sedation, constipation, and respiratory depression.

OPIOID RECEPTORS. Receptors located in the brain and various organs that bind opiates or opioid substances.

OPPORTUNISTIC INFECTION. An infection that is normally mild in a healthy individual, but that takes advantage of an ill person's weakened immune system to move into the body, grow, spread, and cause serious illness.

OPPOSITIONAL DEFIANT DISORDER. A childhood behavioral disorder characterized by an ongoing pattern of disobedient, hostile, and defiant behavior toward authority figures that goes beyond the bounds of normal childhood conduct.

OPTIC ATROPHY. Degeneration of the optic nerve.

OPTIC DISK. The small area in the retina where the optic nerve enters the eye that is not sensitive to light. Also called the blind spot.

OPTIC NERVE. The nerve that carries visual messages from the retina to the brain.

OPTIC NEURITIS. Inflammation of the optic nerve that connects to the retina of the eye. This variable condition can present with any of the following symptoms: blurred vision, loss of visual acuity, loss of some or all color vision, complete or partial blindness, and pain behind the eye.

OPTOKINETIC. A reflex that causes a person's eyes to move when his or her field of vision moves.

OPTOMETRIST. A medical professional who examines and tests the eyes for disease and treats visual disorders by prescribing corrective lenses and/or vision therapy. In many states, optometrists are licensed to use diagnostic and therapeutic drugs to treat certain ocular diseases.

ORAL AND MAXILLOFACIAL SURGEON. A dentist who is trained to perform surgery to correct injuries, defects, or conditions of the mouth, teeth, jaws, and face.

ORAL REHYDRATION SOLUTION (ORS). A liquid preparation developed by the World Health Organization that can decrease fluid loss in persons with diarrhea. Originally developed to be prepared with materials available in the home, commercial preparations are also available.

ORAL SURGEON. A dentist who specializes in surgical procedures of the mouth, including extractions.

ORBIT. The eye socket, which contains the eyeball, muscles, nerves, and blood vessels that serve the eye.

ORCHIECTOMY. Surgical removal of the testes as a way of treating prostate cancer by eliminating the production of testosterone.

ORCHIOPEXY. The surgical securing of the testis to prevent torsion.

ORCHITIS. Inflammation or swelling of the scrotal sac containing the testicles.

ORGAN PROCUREMENT. The process of donor screening and the evaluation, removal, preservation, and distribution of organs for transplantation.

ORGANELLE. Specialized structure within a cell, which is separated from the rest of the cell by a membrane composed of lipids and proteins, where chemical and metabolic functions take place.

ORGANIC BRAIN DISORDER. An organic brain disorder refers to impaired brain function due to damage or deterioration of brain tissue.

ORGANIC FOOD. Food grown without the use of synthetic pesticides and fertilizers.

ORGANIC ILLNESS. A physically, biologically based illness.

ORGANIC MERCURY. Poisonous compounds containing mercury and carbon, such as methylmercury, ethylmercury, and phenylmercury.

ORGANISM. A single, independent life form, such as a bacterium, a plant, or an animal.

ORGASM. The climax of sexual excitement, usually characterized by vaginal contractions by the female and ejaculation of semen by the male.

ORGASMIC DISORDER. The impairment of the ability to reach sexual climax.

ORLISTAT. A drug that inhibits lipase.

OROPHARYNX. The part of the airway into which the mouth leads.

ORPHAN DRUG. A drug that is known to be useful in treatment but lacks sufficient funding for further research and development.

ORTHODONTHIC TREATMENT. The process of straightening teeth to correct their appearance and function.

ORTHOGNATHIC SURGERY. Surgery to alter the relationships of the teeth and/or supporting bones, usually in conjunction with orthodontic treatment.

ORTHOKERATOLOGY. A method of reshaping the cornea using a contact lens. It is not considered a permanent method to reduce myopia.

ORTHOPEDICS. A medical specialty concerned with treating diseases, injuries, and malformations of the bones and supporting structures, such as tendons, ligaments, joints, and muscles.

ORTHOPEDIST. A doctor specializing in treatment of the skeletal system and its associated muscles and joints.

ORTHOPNEA. Difficulty in breathing that occurs while the patient is lying down.

ORTHOPOXVIRUS. The genus of viruses that includes monkeypox, smallpox, cowpox, and camelpox.

ORTHOSIS. An external device, such as a splint or a brace, that prevents or assists movement.

ORTHOSTATIC HYPOTENSION. A drop in blood pressure that causes faintness or dizziness and occurs when one rises to a standing position. Also known as postural hypotension.

ORTHOTIC. A device or brace to control, correct, or compensate for a bone deformity.

ORTHOTIST. A health care professional who is skilled in making and fitting orthopedic appliances.

OSLER'S NODES. Small, raised, reddish, tender areas associated with endocarditis, commonly found inside the fingers or toes.

OSMOLALITY. A measurement of urine concentration that depends on the number of particles dissolved in it. Values are expressed as milliosmols per kilogram (mOsm/kg) of water.

OSMOTHERAPY. Intravenous injection or oral administration of an agent that induces dehydration. The goal of dehydration is to reduce accumulated fluid in the brain.

OSMOTIC PRESSURE. Pressure that occurs when two solutions of differing concentrations are separated by a semipermeable membrane, such as a cellular wall, and the lower concentration solute is drawn across the membrane into the higher concentration solute (osmosis).

OSSICLES. The three small bones of the middle ear: the malleus (hammer), the incus (anvil) and the stapes (stirrup). These bones help carry sound from the eardrum to the inner ear.

OSTEOARTHRITIS. A type of arthritis marked by chronic degeneration of the cartilage of the joints, leading to pain and sometimes loss of function.

OSTEOBLASTS. Bone cells that build new bone tissue.

OSTEOCLASTS. Bone cells that break down and remove bone tissue.

OSTEOCONDUCTION. Provision of a scaffold for the growth of new bone.

OSTEOCYTES. Bone cells that maintain bone tissue.

OSTEOGENESIS. Growth of new bone.

OSTEOGENESIS IMPERFECTA. A genetic disorder involving defective development of connective tissues, characterized by brittle and fragile bones that are easily fractured by the slightest trauma.

OSTEOINDUCTION. Acceleration of new bone formation by chemical means.

OSTEOLYTIC LESION. Soft spot or hole in bone caused by cancer cells.

OSTEOMALACIA. A softening of bones caused by lack of vitamin D and/or calcium in the diet.

OSTEOMYELITIS. An inflammation of bone or bone marrow, often caused by bacterial infections. Chronic melioidosis may cause osteomyelitis.

OSTEOPATHY. A system of medical practice that believes that the human body can make its own remedies to heal infection. It originally used manipulative techniques but also added surgical, hygienic, and medicinal methods when needed.

OSTEOPENIA. Reduction in bone mass, usually caused by a lowered rate of formation of new bone that is insufficient to keep up with the rate of bone destruction. Osteopenia often occurs together with amenorrhea and eating disorders in female athletes. It can lead to premature osteoporosis if left untreated.

OSTEOPHYTE. Also referred to as bone spur, it is an outgrowth or ridge that forms on a bone.

OSTEOPOROSIS. The excessive loss of calcium from the bones, causing the bones to become fragile and break easily. Postmenopausal women are especially vulnerable to this condition because estrogen, a hormone that protects bones against calcium loss, decreases drastically after menopause.

OSTOMY. A surgically created opening in the abdomen for elimination of waste products (urine or stool).

OTIC. Pertaining to the ear.

OTITIS. An infection of the ear.

OTITIS MEDIA. Infection of the middle ear.

OTOLARYNGOLOGIST. A doctor who specializes in diagnosing and treating disorders of the ears, nose, and throat; also called an otorhinolaryngologist.

OTOLOGIC. Relating to the study, diagnosis, and treatment of diseases of the ear and related structures.

OTOSCLEROSIS. A disease that scars and limits the motion of the small conducting bones in the middle ear.

OTOSCOPE. A handheld instrument with a tiny light and a funnel-shaped attachment called an ear speculum, which is used to examine the ear canal and eardrum.

OTOTOXIC. Damaging to the nerves controlling the senses of hearing and balance.

OUTPATIENT SURGERY. Also called same-day or ambulatory surgery. The patient arrives for surgery and returns home on the same day.

OVA. Eggs.

OVAL WINDOW. A tiny opening at the entrance to the inner ear.

OVARIAN CYST. A benign or malignant growth on an ovary. An ovarian cyst can disappear without treatment or become extremely painful and have to be surgically removed.

OVARIAN FOLLICLES. Structures found within the ovary that produce eggs.

OVARIAN TORSION. Twisting of the ovary due to the influence of another condition or disease, resulting in extreme lower abdominal pain.

OVARY. One of the two almond-shaped glands in the female reproductive system responsible for producing eggs and the hormones estrogen and progesterone.

OVERBITE. Protrusion of the upper teeth over the lower teeth.

OVERWEIGHT. A BMI between 25.0 and 30.0.

OVULATION. The phase of the female monthly cycle when a developed egg is released from the ovary into the fallopian tube for possible fertilization.

OVUM (PLURAL, OVA). The reproductive cell of the female, which contains genetic information and participates in the act of fertilization. Also popularly called the egg.

OXALATE. A salt of oxalic acid produced during metabolism and excreted in the urine.

OXIDATION. Interaction in which one molecule removes an electron from another molecule to stabilize itself.

OXYGEN FREE RADICALS. Reactive molecules containing oxygen that can cause cell damage.

OXYGENATED BLOOD. Blood carrying oxygen through the body.

OXYTOCIN. A hormone secreted in the brains of mammals that acts as a neurotransmitter in the brain and also functions in sexual arousal, maternal behavior, and emotional bonding in humans. Synthetic oxytocin is used to induce or support labor in difficult childbirths.

OZONE. A form of oxygen with three atoms in its molecule (O_3), produced by an electric spark or ultraviolet light passing through air or oxygen. Ozone is used therapeutically as a disinfectant and oxidative agent.

P

PACEMAKER. An electrical device that has electrodes attached to the heart to stimulate the heart to beat normally. Pacemakers can be internal (placed under the skin) or external, with the electrodes placed on the skin or threaded through a tube placed into the heart.

PAGET'S DISEASE. A disease, whose cause is unknown, that is generally found in older people. Symptoms include bone pain, bowed legs, curved spine, and broken bones. Another name for this disease is osteitis deformans.

PAGOPHAGIA. The compulsive eating of ice.

PAIN DISORDER. A psychiatric disorder in which pain in one or more parts of the body is caused or made worse by psychological factors. The lower back is one of the most common sites for pain related to this disorder.

PALATINE TONSILS. The tonsils that can be seen at the back of the throat and are the tonsils most commonly affected by tonsillitis.

PALLIATIVE. Referring to any type of treatment that is given to relieve the symptoms of a disease rather than to cure it.

PALLIDOTOMY. A surgical procedure that destroys a small part of a tiny structure within the brain called the globus pallidus internus. This structure is part of the basal ganglia, a part of the brain involved in the control of willed (voluntary) movement of the muscles.

PALLOR. Extreme paleness in the color of the skin.

PALPATE. To examine the body by touching or pressing with the fingers or the palm of the hand.

PALPATION. The examination of the body using the sense of touch. There are two types: light and deep.

PALPEBRAL FISSURE. Eyelid opening.

PALPITATION. Rapid, forceful, throbbing, or fluttering heartbeat.

PALSY. Uncontrolable tremors.

PANCARDITIS. Inflammation of the lining of the heart, the sac around the heart, and the muscle of the heart.

PANCHAKARMA. Intensive Ayurvedic cleansing and detoxification program.

PANCREAS. An elongated gland situated across the back of the abdomen behind the stomach. It secretes both digestive enzymes and hormones. Pancreatic hormones regulate the level of sugar in the blood.

PANCREATECTOMY. Partial or total surgical removal of the pancreas.

PANCREATIC INSUFFICIENCY. Reduction or absence of pancreatic secretions into the digestive system due to scarring and blockage of the pancreatic duct.

PANCREATICODUODENECTOMY. Removal of all or part of the pancreas along with the duodenum. Also known as ''Whipple's procedure'' or ''Whipple's operation.''

PANCREATITIS. Inflammation of the pancreas, either acute (sudden and episodic) or chronic, usually caused by excessive alcohol intake or gallbladder disease.

PANDAS DISORDERS. A group of childhood disorders associated with such streptococcal infections as scarlet fever and strep throat. The acronym stands for Pediatric Autoimmune Neuropsychiatric Disorders Associated with Streptococcal Infections.

PANDEMIC. The occurrence of a disease that in a short time infects a large percentage of the population over a wide geographical area.

PANHYPOPITUITARISM. Generalized decrease of all of the anterior pituitary hormones.

PANIC ATTACK. A time-limited period of intense fear accompanied by physical and cognitive symptoms. Panic attacks may be unexpected or triggered by specific internal or external cues.

PANIC DISORDER. A disorder in which people have sudden and intense attacks of anxiety in certain situations. Symptoms such as shortness of breath, sweating, dizziness, chest pain, and extreme fear often accompany the attacks.

PANNICULITIS. Inflammation of fatty tissue.

PANNUS. Overgrowth of connective tissue on the articular surface of a joint.

PANTETHEINE. A growth factor substance essential in humans, and a constituent of coenzyme A.

PAP TEST. The common term for the Papanicolaou test, a simple smear method of removing cervical cells to screen for abnormalities that indicate cancer or a precancerous condition.

PAPAVERINE. A smooth muscle relaxant sometimes injected into the penis as a treatment for impotence.

PAPILLARY CARCINOMA. A type of breast cancer that primarily occurs in older women. On ultrasound, this type of tumor may look like a solid or complex mass, or it may show up as solid tissue protruding into a cyst.

PAPILLOMA. A benign growth on the skin or mucous membrane. Viruses that cause these growths are called human papillomaviruses (HPVs).

PAPILLOMAVIRUS. A member of a group of viruses associated with warts and cervical cancer.

PAPULE. A small hard elevation of the skin.

PARACENTESIS. A procedure in which fluid is drained from a body cavity by means of a catheter placed through an incision in the skin.

PARALYSIS. Loss of the ability to move one or more parts of the body.

PARAMYXOVIRUS. A genus of viruses that includes the causative agent of mumps.

PARANEOPLASTIC SYNDROME. A set of symptoms that is associated with cancer but is not directly caused by the cancer.

PARANOIA. An unfounded or exaggerated distrust of others, sometimes reaching delusional proportions.

PARAPHILIA. Recurring strong sexual arousal to fantasies, objects, situations, or individuals that are not considered normal in the individual's culture.

PARAPHIMOSIS. The entrapment of a retracted foreskin behind the coronal sulcus, a groove that separates the shaft and head of the penis.

PARAPROTEIN. M-protein; abnormal immunoglobulin produced in multiple myeloma.

PARASITE. An organism that lives and feeds in or on another organism (the host) and does nothing to benefit the host.

PARASITIC. Of or relating to a parasite.

PARASOMNIA. A primary sleep disorder in which the person's physiology or behaviors are affected by sleep, the sleep stage, or the transition from sleeping to waking.

PARASYMPATHETIC NERVOUS SYSTEM. The division of the autonomic (involuntary or unwilled) nervous system that slows heart rate, increases digestive and gland activity, and relaxes the sphincter muscles that close off body organs.

PARASYMPATHOMIMETIC. An agent whose effects mimic those resulting from stimulation of the parasympathetic nerves.

PARENTERAL. Administered inside the body but outside the digestive tract.

PARENTERAL NUTRITION. Liquid nutrition provided through tubes that are placed in the veins.

PARESTHESIA. A prickly, tingling, or burning sensation on the skin.

PARIETAL CELLS. Cells of the gastric glands in the stomach lining that secrete hydrochloric acid.

PARKINSON'S DISEASE. A neurological disorder caused by deficiency of dopamine, a neurotransmitter, which is a chemical that assists in transmitting messages between the nerves within the brain. It is characterized by muscle tremor or palsy and rigid movements.

PARKINSONISM. A group of conditions that all have these typical symptoms in common: tremor, rigidity, slow movement, and poor balance and coordination.

PARONYCHIA. Inflammation of the folds of skin that surround a nail.

PAROTID GLAND. The salivary gland that lies below and in front of each ear.

PAROTITIS. Inflammation and swelling of the salivary glands.

PAROXETINE HYDROCHLORIDE. An SSRI that is used to treat mental depression, OCD, anxiety, and various other disorders.

PAROXYSM. A sudden attack of symptoms.

PAROXYSMAL NOCTURNAL DYSPNEA (PND). A form of dyspnea characterized by the patient's waking from sleep unable to breathe.

PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH). A rare complement disorder characterized by episodes of red blood cell destruction (hemolysis) and blood in the urine (hemoglobinuria) that is worse at night.

PARTIAL DENTURE. A removable bridge that usually clasps onto only one abutment.

PARTIAL PARENTERAL NUTRITION (PPN). Partial nutrition obtained by the injection of a solution containing some essential nutrients into a vein; intended to temporarily supplement the diet when a patient cannot tolerate consuming enough food to meet daily nutritional requirements.

PARTIAL PRESSURE. The pressure exerted by one of the gases in a mixture of gases. The partial pressure of the gas is proportional to its concentration in the mixture. The total pressure of the gas mixture is the sum of the partial pressures of the gases in it (Dalton's Law) and as the total pressure increases, each partial pressure increases proportionally.

PARTIAL SEIZURE. A seizure that starts in one particular part of the brain. The abnormal electrical activity may remain confined to that area, or may spread to the entire brain. Also called a focal seizure.

PARTIAL THROMBOPLASTIN TIME. A test that checks the clotting factors of the intrinsic pathway.

PASSIVE IMMUNITY. Immunity produced by providing a person with antibodies from another source than self. Infants are born with passive immunity acquired from their mothers.

PASSIVE IMMUNIZATION. Treatment that provides immunity through the transfer of antibodies obtained from an immune individual.

PASTEURELLOSIS. A bacterial infection caused by *Pasteurella multocida*. Pasteurellosis is characterized by inflammation around the wound site and may be accompanied by bacteria in the bloodstream and infection in tissues and organs.

PASTEURIZATION. A process during which milk is heated up and maintained at a particular temperature long enough to kill bacteria.

PASTIA'S LINES. Red lines in the folds of the skin, especially in the armpit and groin, that are characteristic of scarlet fever.

PATCH TEST. Test in which different antigens (substances that cause an allergic reaction) are introduced into a patient's skin via a needle prick or scratch and then observed for evidence of an allergic reaction to one or more of them. Also known as a scratch test.

PATELLA. The kneecap.

PATENCY. Being widely open. A blood vessel that has been widened or reopened is said to be patent.

PATENT DUCTUS ARTERIOSUS. A congenital defect in which the temporary blood vessel connecting the left pulmonary artery to the aorta in the fetus doesn't close in the newborn.

PATERNAL. From one's father.

PATHOGEN. Any biological agent that causes illness or disease in its host. A pathogen may be a virus, bacterium, fungus, or prion.

PATHOGENIC. Disease-causing.

PATHOLOGIC. Characterized by disease or the structural and functional changes due to disease. Pathologic heart murmurs may indicate a heart defect.

PATHOLOGIST. A doctor who specializes in the diagnosis of disease by studying cells and tissues under a microscope.

PATHOLOGY. The branch of medicine that looks at the abnormal changes in cells and tissues that signal disease.

PATIENT YEARS. In clinical trials, the number of patients multiplied by the number of years that they were followed in a study divided by the number of study events that occurred.

PAUCIARTICULAR JUVENILE RA. Rheumatoid arthritis (RA) found in children that affects less than four joints.

PAVOR NOCTURNUS. Another term for sleep terror disorder.

PCI. A type of radiotherapy that is used to prevent tumors from growing in the brain.

PEAK FLOW. A measurement of the maximum speed of a patient's expiration (breathing out). It is also known as the peak expiratory flow rate or PEFR. Peak flow is measured by a small handheld device called a peak flow meter.

PECTUS CARINATUM. An abnormality of the chest in which the sternum (breastbone) is pushed outward. It is sometimes called "pigeon breast."

PECTUS EXCAVATUM. An abnormality of the chest in which the sternum (breastbone) sinks inward; sometimes called "funnel chest."

PEDICLE FLAP. A section of tissue, with its blood supply intact, that is maneuvered to another part of the body; also called an attached flap.

PEDICULICIDE. Any substance that kills lice.

PEDICULOSIS (PLURAL, PEDICULOSES). A lice infestation.

PEDOPHILE. A person who sexually abuses children.

PEDOPHILIA. A sexual perversion in which children are the preferred sexual object.

PEG-ADA. An orphan drug that is useful in treating severe combined immunodeficiency related to adenosine deaminase deficiency.

PELLEGRA. A condition caused by a dietary deficiency of one of the B vitamins, called niacin.

PELVIC EXAM. A gynecological exam of the female reproductive organs.

PELVIC EXENTERATION. Extensive surgery to remove the uterus, ovaries, pelvic lymph nodes, part or all of the vagina, and the bladder, rectum, and/or part of the colon.

PELVIC INFLAMMATORY DISEASE (PID). Inflammation of the female genital tract, especially of the fallopian tubes, caused by any of several microorganisms, chiefly chlamydia and gonococci, and characterized by severe abdominal pain, high fever, vaginal discharge, and in some cases destruction of tissue that can result in sterility.

PELVIC ORGANS. The organs inside of the body that are located within the confines of the pelvis. This includes the bladder and rectum in both sexes and the uterus, ovaries, and fallopian tubes in females.

PEMPHIGUS. An autoimmune disorder in which the immune system produces antibodies against specific proteins in the skin and mucous membrane. These antibodies produce a reaction that leads to a separation of skin cells.

PENICILLAMINE (CUPRIMINE, DEPEN). A drug used to treat medical problems (such as excess copper in the body and rheumatoid arthritis) and to prevent kidney stones. It is also sometimes prescribed to remove excess lead from the body.

PENICILLIN. An antibiotic that is used to treat bacterial infections.

PENTAMIDINE ISETHIONATE. An antibiotic used to treat and prevent pneumocystis pneumonia.

PEPTIC. Induced by or associated with the action of digestive secretions.

PEPTIC ULCER. A wound in the bowel that can be caused by stomach acid or a bacterium called *Helicobacter pylori*.

PEPTIC ULCER DISEASE (PUD). A stomach disorder marked by corrosion of the stomach lining due to the acid in the digestive juices.

PERCUSSION. An assessment method in which the surface of the body is struck with the fingertips to obtain sounds that can be heard or vibrations that can be felt. It can determine the position, size, and consistency of an internal organ. It is done over the chest to determine the presence of normal air content in the lungs, and over the abdomen to evaluate air in the loops of the intestine.

PERCUTANEOUS. Performed through the skin, from the Latin *per*, meaning through, and *cutis*, meaning skin.

PERCUTANEOUS BIOPSY. A biopsy in which a needle is inserted and a tissue sample removed through the skin.

PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY. An x-ray examination of the bile ducts. A needle is passed through the skin (percutaneous) across or over the liver (transhepatic) and directly into a bile duct to inject a contrast dye. The dye enhances the x-ray image mapping the system of bile ducts (cholangiography).

PERENNIAL. Present at all seasons of the year.

PERFECT USE. A measurement of the effectiveness of a contraceptive based only on those who use the method correctly and use it every time they have intercourse. It is also called the method effectiveness rate.

PERFORATION. A hole.

PERFUSION. Blood flow through an organ or tissue.

PERFUSION LUNG SCAN. A scan that shows the pattern of blood flow in the lungs.

PERICARDIAL EFFUSION. An accumulation of excess fluid in the pericardial sac that surrounds the heart.

PERICARDIOCENTESIS. A procedure used to drain fluid out of the sac surrounding the heart. This is done by inserting a needle through the chest and into the sac.

PERICARDITIS. Inflammation of the pericardium, the membrane surrounding the heart.

PERICARDIUM. The pericardium is the thin, sac-like membrane that surrounds the heart. It has two layers: the serous pericardium and the fibrous pericardium.

PERICORONITIS. A gum condition in which irritation and inflammation are produced by the crown of an incompletely erupted tooth.

PERINATAL. Refers to the period shortly before and after birth, generally from around the 20th week of pregnancy to one to four weeks after birth.

PERINATAL INFECTION. A maternal infection that is transmitted to the fetus after membrane rupture or during labor or delivery.

PERINATOLOGIST. A specialist in the branch of obstetrics that deals with high-risk pregnant women.

PERINEUM. The area between the thighs that lies behind the genital organs and in front of the anus; also known as the perineal area.

PERIODIC LIMB MOVEMENTS IN SLEEP (PLMS). Random movements of the arms or legs that occur at regular intervals of time during sleep.

PERIODONTAL. Pertaining to the gums.

PERIODONTITIS. A gum disease that destroys the structures supporting the teeth, including bone.

PERIOSTEUM. A fibrous vascular membrane that covers bones.

PERIPHERAL NERVES. Nerves throughout the body that carry information to and from the spinal cord.

PERIPHERAL NERVOUS SYSTEM (PNS). One of the two major divisions of the nervous system. PNS nerves link the central nervous system with sensory organs, muscles, blood vessels, and glands.

PERIPHERAL NEUROPATHY. A disease affecting the portion of the nervous system outside the brain and spinal chord. One or more nerves can be involved, causing sensory loss, muscle weakness and shrinkage, and decreased reflexes.

PERIPHERAL PRECOCIOUS PUBERTY. Precocious puberty resulting from the presence of sex steroids independent of the activation of the HPG axis. It is also called precocious pseudopuberty.

PERIPHERAL STEM CELL TRANSPLANT. The process of transplanting peripheral stem cells instead of using bone marrow. The stem cells in the circulating blood that are similar to those in the bone marrow are given to the patient after treatment to help the bone marrow recover and continue producing healthy blood cells. A peripheral stem cell transplant may also be used to supplement a bone marrow transplant.

PERIPHERAL STEM CELLS. Stem cells that are taken directly from the circulating blood and used for transplantation. Stem cells are more concentrated in the bone marrow, but they can also be extracted from the bloodstream.

PERIPHERAL VASCULAR DISEASE. A disease affecting blood vessels, especially in the arms, legs, hands, and feet.

PERIPHERAL VISION. The ability to see objects that are not located directly in front of the eye. Peripheral vision allows people to see objects located on the side or edge of their field of vision.

PERISTALSIS. The waves of muscular contraction in the intestines that push the food along during the process of digestion.

PERITONEAL FLUID. Fluid from the abdominal cavity.

PERITONEUM. The transparent membrane lining the abdominal cavity that holds organs, such as the intestines, in place.

PERITONITIS. Inflammation of the peritoneum, the membrane surrounding the abdominal contents.

PERMEABLE. Capable of allowing substances to pass through.

PERMETHRIN. A synthetic pyrethroid for killing lice.

PERNICIOUS ANEMIA. One of the main types of anemia, caused by inadequate absorption of vitamin B_{12}. Symptoms include tingling in the hands, legs, and feet; spastic movements; weight loss; confusion; depression; and decreased intellectual function.

PEROXIDE. A bleaching agent that is a compound consisting of two atoms of oxygen connected by a single bond.

PEROXINS. Proteins that are responsible for forming the peroxisomal membrane and transporting other proteins into the peroxisome; these proteins are encoded by various PEX genes.

PEROXISOME. A cellular organelle or microbody that contains various enzymes that are responsible for the production of cellular components and the breakdown of toxic waste products.

PEROXISOME BIOGENESIS DISORDER (PBD). An inherited disorder that disrupts the formation and functioning of peroxisomes.

PERPETRATOR. The legal term for a person who commits a crime.

PERSECUTORY DELUSION. A fixed, false, and inflexible belief that others are engaging in a plot or plan to harm an individual.

PERSEVERATION. Continuous involuntary repetition of speech or behavior.

PERSONALITY. The organized pattern of behaviors and attitudes that makes a human being distinctive. Personality is formed by the ongoing interaction of temperament, character, and environment.

PERVASIVE DEVELOPMENTAL DISORDER (PDD). The term used by the American Psychiatric Association for individuals who meet some but not all of the criteria for autism.

PESSARY. A device inserted into the vagina to support sagging organs.

PETECHIAE. Small pinpoint hemorrhages in skin or mucous membranes caused by the rupture of capillaries.

PETROLEUM JELLY OR OINTMENT. Petrolatum, a gelatinous substance obtained from oil that is used as a protective dressing.

PEYRONIE'S DISEASE. A disease resulting from scarring of the corpus cavernosa, causing painful erections.

PH. A measure of the acidity of a fluid. On a scale of 1 to 14, a pH of 7 is neutral. Higher pH readings are alkaline and lower pH readings are acidic.

PHACOEMULSIFICATION. Surgical procedure to remove a cataract using sound waves to disintegrate the lens, which is then removed by suction.

PHAGOCYTIC CELLS. A cell that ingests microorganisms and foreign particles.

PHAGOCYTOSIS. A process by which a white blood cell envelopes and digests debris and microorganisms to remove them from the blood.

PHALANX. A bone of the fingers or toes.

PHALILALIA. Involuntary echoing of the last word, phrase, sentence, or sound vocalized by oneself.

PHANTOM LIMB. The perception that a limb is present (and throbbing with pain) after it has been amputated.

PHANTOM PAIN. Pain, tingling, itching, or numbness in the place where an amputated limb used to be.

PHARMACEUTICAL. Pertaining to drugs.

PHARMACO-DYNAMICS. The study of the relationships and interactions of herbs.

PHARMACOLOGICAL. Referring to therapy that relies on drugs.

PHARYNGITIS. Inflammation of the throat, accompanied by dryness and pain.

PHARYNX. The muscular cavity that leads from the mouth and nasal passages to the larynx and esophagus.

PHASE CONTRAST MICROSCOPE. A light microscope in which light is focused on the sample at an angle to produce a clearer image.

PHENOTHIAZINE-DERIVATIVE DRUGS. A large family of drugs derived from phenothiazine, a compound that in itself is too poisonous for human consumption. Phenothiazine derivatives include tranquilizers, medications that prevent vomiting, antihistamines, and drugs used to enhance the effectiveness of anesthesia.

PHENTERMINE. An amphetamine prescribed for appetite suppression.

PHENYLALANINE. An essential amino acid that must be obtained from food since the human body cannot manufacture it.

PHENYLKETONURIA (PKU). An enzyme deficiency present at birth that disrupts metabolism and causes brain damage. This rare inherited defect may be linked to the development of autism.

PHENYTOIN (DILANTIN). Anti-convulsive medication used to treat seizure disorders.

PHEOCHROMOCYTOMA. A tumor of specialized cells of the adrenal gland.

PHILADELPHIA CHROMOSOME. An abnormal chromosome that is found in patients with chronic myelogenous leukemia.

PHIMOSIS. A tightening of the foreskin that may close the opening of the penis.

PHLEBITIS. Inflammation of a vein.

PHLEBOTOMIST. Health care professional trained to obtain samples of blood.

PHLEBOTOMY. Drawing blood from a vein for diagnosis or treatment. Phlebotomy is sometimes used in the treatment of hemoglobinopathies to lower the iron concentration of the blood.

PHLEGM. Thick mucus produced in the air passages.

PHOBIA. A fear of a specific situation, object, or type of object. Phobias are often considered illogical or irrational, as the situation or object does not pose any significant danger for the individual experiencing the phobia.

PHONICS. A system to teach reading by teaching the speech sounds associated with single letters, letter combinations, and syllables.

PHOROPTER. The instrument used to measure refractive status of the eyes. It contains many lenses that are changed in front of the eyes while the patient is looking at an eye chart. The patient is asked to choose which lens produces a clearer image.

PHOSPHODIESTERASE–5 (PDE5) INHIBITORS. The drugs Viagra, Levitra, and Cialis, which are used to treat erectile dysfunction.

PHOTOCOAGULATION. Cancer treatment in which the tumor is destroyed by an intense beam of laser light.

PHOTODYNAMIC THERAPY (PDT). A treatment for tumors in which a light-sensitive dye is injected into the blood (or skin) to be taken up selectively by the tumors. Light of a specific wavelength is then applied to the affected area to kill the tumors.

PHOTON. A light particle.

PHOTOPHOBIA. An extreme sensitivity to light.

PHOTOPIGMENT. Pigment that is most sensitive to a particular wavelength of light.

PHOTORECEPTORS. Specialized nerve cells (rods and cones) in the retina that are responsible for vision.

PHOTOREFRACTIVE KERATECTOMY (PRK). A type of refractive eye surgery using a laser to change the shape of the cornea.

PHOTOSENSITIVITY. An abnormally heightened reaction to light.

PHOTOSENSITIZER. A chemical compound that can be excited (activated) by light of a specific wavelength.

PHOTOTHERAPY. Also called light therapy, the patient is exposed to a bright light to compensate for reduced exposure to sunlight.

PHOTOTOXIC. Causes a harmful skin reaction when exposed to sunlight.

PHYLLOQUINONE. An alternate name for vitamin K_1.

PHYSIATRIST. A physician who specializes in physical medicine.

PHYSICAL ACTIVITY. Any activity that involves moving the body and burning calories.

PHYSICAL FITNESS. A combination of muscle strength, cardiovascular health, and flexibility that is usually attributed to regular exercise and good nutrition.

PHYSICAL MANIPULATION. The use of deep massage, spinal alignment, and joint manipulation to stimulate tissues.

PHYSIOLOGIC. Refers to physiology, particularly normal, healthy, physical functioning.

PHYSIOLOGICAL. Dealing with the functions and processes of the body.

PHYTO- (AS IN PHYTOCHEMICAL, PHYTOMEDICINAL, AND PHYTOTHERAPY). Meaning, or pertaining to, a plant or plants.

PHYTOESTROGENS. Compounds found in plants that can mimic the effects of estrogen in the body.

PIA MATER. The innermost layer of the meninges.

PICA. A medical disorder characterized by cravings for dirt, ice cubes, paper, starch, clay, or other non-nutritive items. It is often a sign of iron deficiency or hemolytic anemia.

PICK'S DISEASE. A rare type of primary dementia that affects the frontal lobes of the brain. It is characterized by a progressive loss of social skills, language, and memory, leading to personality changes and sometimes loss of moral judgment.

PIGEON BREAST (ALSO KNOWN AS PECTUS CARINATUM). A chest shape with a central projection resembling the keel of a boat.

PILONIDAL CYST. A special kind of abscess that occurs in the cleft between the buttocks. Forms frequently in adolescence after long trips that involve sitting.

PINWORM. Enterobius vermicularis, a nematode worm of the family Oxyuridae that causes parasitic infestation of the intestines and cecum. Pinworm is endemic in both temperate and tropical regions and common especially in school age children.

PIPERONYL BUTOXIDE. A liquid organic compound that enhances the activity of insecticides.

PIRIFORMIS. A muscle in the pelvic girdle that is closely associated with the sciatic nerve.

PITTING EDEMA. A swelling in the tissue under the skin, resulting from fluid accumulation, that is measured by the depth of indentation made by finger pressure over a boney prominence.

PITUITARY GLAND. A gland located at the base of the brain and controlled by the hypothalamus. It controls most endocrine functions and is responsible for things such as kidney function, lactation, and growth and development.

PLACEBO. A pill or liquid given during the study of a drug or dietary supplement that contains no medication or active ingredient. Usually study participants do not know if they are receiving a pill containing the drug or an identical-appearing placebo.

PLACENTA. The organ that provides oxygen and nutrition from the mother to the fetus during pregnancy. The placenta is attached to the wall of the uterus and leads to the fetus via the umbilical cord.

PLACENTA PREVIA. A low-lying placenta that covers part or all of the inner opening of the cervix. This can result in heavy bleeding during labor and delivery, which can be dangerous for the mother and baby.

PLACENTAL ABRUPTION. Separation of the placenta from the uterine wall before the baby is born, cutting off blood flow to the baby.

PLAGUE. A highly infectious disease that can be fatal if not treated promptly. The bacteria that cause plague mainly infect rats, mice, squirrels, and other wild rodents. The disease is passed to people through fleas. Infected people can then spread the disease to other people.

PLANTAR FASCIA. A tough fibrous band of tissue surrounding the muscles of the sole of the foot. Also called plantar aponeurosis.

PLAQUE. A compound made up of fat, cholesterol, calcium, and other substances found in the blood. It can stick to the walls of arteries, partially or totally blocking blood flow.

PLAQUE (DENTAL). A sticky film of saliva, food particles, and bacteria that attaches to the tooth surface and causes decay.

PLASMA. Clear, yellow- or straw-colored fluid that is the liquid component of blood and lymphatic fluid.

PLASMA CELL. Type of white blood cell that produces antibodies; derived from an antigen-specific B cell.

PLASMALOGEN. Any of a group of phospholipids; plasmalogen synthesis is disrupted in ZS.

PLASMAPHERESIS. Plasma exchange transfusion; the separation of serum from blood cells to treat hyperviscosity of the blood.

PLATELET. A small, disk-shaped body in the blood that has an important role in blood clotting: they form the initial plug at the rupture site of a blood vessel.

PLATELET AGGREGATION. The clumping together of blood cells, possibly forming a clot.

PLATYPNEA. Dyspnea that occurs when the patient is sitting up.

PLETHYSMOGRAPHY. A test in which a patient sits inside a booth called a plethysmograph and breathes through a mouthpiece, while pressure and air flow measurements are collected to measure the total lung volume.

PLEURA OR PLEURAE. A delicate membrane that encloses the lungs. The pleura is divided into two areas separated by fluid–the visceral pleura, which covers the lungs, and the parietal pleura, which lines the chest wall and covers the diaphragm.

PLEURAL. Pleural refers to the pleura or membrane that enfolds the lungs.

PLEURAL CAVITY. The space surrounding the lungs, including the membranes covering the lungs and lining the inside of the chest wall.

PLEURAL EFFUSION. An abnormal accumulation of fluid in the pleura, a fibrous membrane that lines the inside of the chest cavity and protects the lungs. This accumulation can cause shortness of breath, cough, and chest pain.

PLEURAL SPACE. The small space between the two layers of the membrane that covers the lungs and lines the inner surface of the chest.

PLEURISY. Chest pain that occurs when a person takes a deep breath.

PLEURITIS. Inflammation of the pleura, the membrane surrounding the lungs.

PNEUMOCOCCAL. Infection by the bacterium *Streptococcus pneumoniae*) that causes acute pneumonia.

PNEUMOCONIOSIS (PLURAL, PNEUMOCONIOSES). Any chronic lung disease caused by inhaling particles of silica or similar substances that lead to loss of lung function.

***PNEUMOCYSTIS CARINII* PNEUMONIA (PCP).** A severe lung infection caused by a parasitic protozoan. The disease mainly affects people with weakened immune systems, such as people with AIDS.

PNEUMOCYSTOSIS. Another name for active PCP infection.

PNEUMONIA. A disease in which the lungs become inflamed. Pneumonia may be caused by bacteria, viruses, or other organisms, or by physical or chemical irritants.

PNEUMONITIS (ASPIRATION). Inflammation of the lung caused by inhaling a liquid, usually carbon based.

PNEUMOTHORAX. Presence of gas or air in the hollow space around the lungs.

PNEUMOVAX. A vaccine that is given to splenectomy patients to protect them against bacterial infections. Other vaccines include Pnu-Imune and Menomune.

PODIATRIST. A physician who specializes in the medical care and treatment of the human foot.

PODIATRY. A medical specialty concerned with treating diseases, injuries, and malformations of the feet.

PODOPHYLLUM RESIN. A medication derived from the May apple or mandrake and used to treat genital warts.

POINT OF VIEW. In a person with dyslexia, this term is used to describe the angle from which their mind's eye views an object. This point of view may be unanchored and moving about, as if several different people were telling what they see all at the same time.

POLYARTHRITIS. A nonspecific term for arthritis involving two or more joints, typically associated with auto-immune forms of arthritis. Symptoms usually include pain, inflammation, and/or swelling in multiple joints.

POLYARTICULAR JUVENILE RA. Rheumatoid arthritis found in children that affects more than four joints.

POLYCARBONATE. A very strong type of plastic often used in safety glasses, sport glasses, and children's eyeglasses. Polycarbonate lenses have approximately 50 times the impact resistance of glass lenses.

POLYCYSTIC KIDNEY DISEASE. A hereditary kidney disease that causes fluid- or blood-filled pouches of tissue called cysts to form on the tubules of the kidneys. These cysts impair normal kidney function.

POLYCYSTIC OVARIAN SYNDROME (PCOS). A condition in which the eggs are not released from the ovaries and instead form multiple cysts.

POLYCYSTIC OVARY DISEASE. A condition in which a woman has little or no menstruation, is infertile, has excessive body hair, and is obese. The ovaries may contain several cysts.

POLYCYTHEMIA VERA. A condition characterized by an unusually large number of red blood cells in the blood due to increased production by the bone marrow. Symptoms include headaches, blurred vision, high blood pressure, dizziness, and night sweats.

POLYDIPSIA. Excessive thirst.

POLYGENIC. A trait or disorder that is determined by several different genes. Most human characteristics,

including height, weight, and general body build, are polygenic. Schizophrenia and late-onset AD are considered polygenic disorders.

POLYMER. A substance formed by joining smaller molecules. For example, plastic, acrylic, cellulose acetate, cellulose propionate, nylon, etc.

POLYMERASE CHAIN REACTION (PCR). A test performed to evaluate false-negative results to the ELISA and Western blot tests. Numerous copies of a gene are made by separating the two strands of DNA containing the gene segment, marking its location, using DNA polymerase to make a copy, and then continuously replicating the copies. The amplification of gene sequences that are associated with HIV allows for detection of the virus by this method.

POLYMYOSITIS. An inflammation of many muscles.

POLYP. A lump of tissue protruding from the lining of an organ, such as the nose, bladder, or intestine. Polyps can sometimes block the passages in which they are found.

POLYPOSIS. The medical term for the development of multiple polyps on a body part.

POLYSOMNOGRAPHY. A technique for diagnosing sleep disorders with the use of a machine that records the pulse, breathing rate, and other variables while the patient sleeps.

POLYUNSATURATED FAT. Fats that contain two or more double or triple bonds per molecule; examples include fish, safflower, sunflower, corn, and soybean oils.

POLYURIA. Excessive secretion of urine.

PONTIC. An artificial tooth.

PORNOGRAPHY. Sexually explicit pictures, writings, or other material produced for the purpose of sexual arousal.

PORPHYRIA. A disorder in which porphyrins build up in the blood and urine.

PORPHYRIN. A type of pigment found in living things, such as chlorophyll, which makes plants green, or hemoglobin, which makes blood red.

PORTABLE CHEST X RAY. An x ray procedure taken by equipment that can be brought to the patient. The resulting radiographs may not be as high in quality as stationary x-ray radiographs.

PORTAL. An entrance or a means of entrance.

PORTAL HYPERTENSION. A condition caused by cirrhosis of the liver. It is characterized by impaired or reversed blood flow from the portal vein to the liver, an enlarged spleen, and dilated veins in the esophagus and stomach.

PORTAL VEIN. The blood vessel carrying venous blood from the abdominal organs to the liver.

PORTAL VEIN THROMBOSIS. The development of a blood clot in the vein that brings blood into the liver. Untreated portal vein thrombosis causes portal hypertension.

POSITIVE SYMPTOMS. Symptoms of schizophrenia that are characterized by the production or presence of behaviors that are grossly abnormal or excessive, including hallucinations and thought–process disorder. DSM–IV subdivides positive symptoms into psychotic and disorganized.

POSITRON. One of the small particles that make up an atom. A positron has the same mass and amount of charge as an electron, but the positron has a positive charge.

POSITRON EMISSION TOMOGRAPHY (PET) SCAN. An imaging system that creates a picture showing the location of tumor cells in the body. A substance called radionuclide dye is injected into a vein, and the PET scanner rotates around the body to create the picture.

POSTEXPOSURE PROPHYLAXIS (PEP). Any treatment given after exposure to a disease to try to prevent the disease from occurring.

POST-HERPETIC NEURALGIA (PHN). Long-lasting nerve pain caused by herpes zoster.

POSTMENOPAUSAL. A term referring to the time period following menopause.

POSTMORTEM. Referring to the period following death.

POSTPARTUM. Referring to the time period following childbirth.

POST-TRAUMATIC STRESS DISORDER (PTSD). A psychological reaction that continues long after a highly stressful event and is characterized by depression, anxiety, flashbacks, and nightmares.

POSTURAL DRAINAGE. Techniques to help expel excess mucus by specific poistions of the body (that decrease the effects of gravity) combined with manual percussion and vibration over various parts of the lung.

POSTURAL HYPOTENSION (ORTHOSTATIC HYPOTENSION). A sudden drop in blood pressure when rising from a sitting or lying down position.

POTASSIUM. A mineral found in whole grains, meat, legumes, and some fruits and vegetables, which is important for many body processes, including proper functioning of the nerves and muscles.

POTENTIZATION. The process of increasing the power of homeopathic preparations by successive dilutions and succussions of a mother tincture.

POTENTIZE. The process of transferring the healing energy of a plant into spring water.

POVERTY OF SPEECH. A negative symptom of schizophrenia, characterized by brief and empty replies to questions. It should not be confused with shyness or reluctance to talk.

POX. A pus-filled bump on the skin.

PRADER-WILLI SYNDROME. An uncommon genetic disorder that causes a constant feeling of hunger.

PRAKRITI. An individual's unique dosha pattern.

PRANA. Life sustaining energy centered in the human brain; the first of the five airs of Ayurvedic philosophy; the life force governing inspiration and the conscious intellect.

PRANAYAMA. Yoga method of breathing.

PRECANCEROUS. Abnormal and with a high probability of turning into cancer, but not yet a cancer.

PRECIPITIN. An antibody in blood that combines with an antigen to form a solid that separates from the rest of the blood.

PRECOCIOUS. Developing at an unusually early age.

PRECONCEPTIONAL. This refers to the time period before pregnancy, i.e., conception, occurs.

PREDNISONE. A corticosteroid often used to treat inflammation.

PREECLAMPSIA AND ECLAMPSIA. Disorders of late pregnancy associated with high blood pressure, fluid retention, and protein in the urine. They can cause stillbirth.

PREGNANCY CATEGORY. A system of classifying drugs according to their established risks for use during pregnancy. Category A: Controlled human studies have demonstrated no fetal risk. Category B: Animal studies indicate no fetal risk, but no human studies, or adverse effects in animals, but not in well-controlled human studies. Category C: No adequate human or animal studies, or adverse fetal effects in animal studies, but no available human data. Category D: Evidence of fetal risk, but benefits outweigh risks. Category X: Evidence of fetal risk. Risks outweigh any benefits.

PREMALIGNANT SKIN LESION. An abnormal change in the skin that has a good chance of turning into skin cancer but is not yet cancerous.

PREMATURE ATRIAL BEAT. A beat that occurs before it would normally be expected.

PREMATURE DELIVERY. The birth of a live baby when a pregnancy ends spontaneously after the twentieth week.

PREMATURE EJACULATION. Rapid ejaculation before the person wishes it, usually in less than one to two minutes after beginning intercourse.

PREMENSTRUAL DYSPHORIC DISORDER (PMDD). Premenstrual syndrome (PMS); symptoms including back and abdominal pain, nervousness and irritability, headache, and breast tenderness that occur the week before menstruation.

PREMENSTRUAL SYNDROME. (PMS) A set of symptoms that occur in some women 2–14 days before they begin menstruating each month. Symptoms include headache, fatigue, irritability, depression, abdominal bloating, and breast tenderness.

PREMUTATION. A change in a gene that precedes a mutation; this change does not alter the function of the gene.

PRENATAL DIAGNOSIS. The determination of whether a fetus possesses a disease or disorder while it is still in the womb.

PRENATAL INFECTION. A maternal infection that is transmitted to the fetus through the placenta.

PRENATAL TESTING. Testing for a disease such as a genetic condition in an unborn baby.

PREPUCE. The fold of tissue covering the clitoris in females and the tip of the penis in males.

PRESBYOPIA. A condition affecting people over the age of 40 where the system of accommodation that allows focusing of near objects fails to work because of age-related hardening of the lens of the eye.

PRESENILE DEMENTIA. The original name for Alzheimer's disease.

PRESENILIN (PSEN). Presenilin 1 and presenilin 2 are proteins that are involved in processing amyloid precursor protein (APP). Mutations in the genes encoding these proteins can cause early-onset AD.

PRESENTATION. The part of the fetus's body that enters into the birth canal first.

PRESSURE POINTS. Specific locations on the feet and hands that correspond to nerve endings that connect to the organs and glands of the human body via the spinal cord.

PRESSURE ULCER. Also known as a decubitus ulcer, pressure ulcers are open wounds that form whenever prolonged pressure is applied to skin covering bony outcrops of the body. Patients who are bedridden are at risk of developing pressure ulcers. Pressure ulcers are commonly known as bedsores.

PRETERM LABOR. Labor before the thirty-seventh week of pregnancy.

PREVALENCE. The percentage of a population that is affected by a specific disease at a given time.

PRIAPISM. A prolonged erection lasting more than four hours.

PRIMARY ENERGY PATTERN. A spiral motion that radiates from the umbilicus; the energy pattern associated with a child in the womb.

PRIMARY GAIN. The immediate relief from guilt, anxiety, or other unpleasant feelings that a patient derives from a symptom.

PRIMARY HEADACHE. A headache that is not caused by another disease or medical condition. Tension headaches are a subtype of primary headache.

PRIMARY PERSONALITY. The core personality of an dissociative identity disorder patient. In women, the primary personality is often timid and passive, and may be diagnosed as depressed.

PRIMARY PROGRESSIVE. A pattern of symptoms of multiple sclerosis in which the disorder progresses without remission, or with occasional plateaus or slight improvements.

PRIMARY SCLEROSING CHOLANGITIS. A chronic disease in which the immune system fails to recognize the cells that compose the bile ducts as part of the same body, and attempts to destroy them. It is frequently associated with another inflammatory disease of the digestive tract, ulcerative colitis.

PRIMARY SLEEP DISORDER. A sleep disorder that cannot be attributed to a medical condition, another mental disorder, or prescription medications or other substances.

PRIMING MEMORY. The memory system that joins perceptual and conceptual representations.

PROBENECID. A drug that corrects hyperuricemia by increasing the urinary excretion of urate.

PROBIOTICS. Food supplements containing live bacteria or other microbes intended to improve or restore the normal balance of microorganisms in the digestive tract.

PROCAINE PENICILLIN. An injectable form of penicillin that contains an anesthetic to reduce the pain of the injection.

PROCESS ADDICTION. Addiction to certain mood-altering behaviors, such as eating, gambling, sexual activity, overwork, and shopping.

PROCESSUS VAGINALIS. A pouch of the peritoneum (lining of the abdominal cavity) that is carried into the scrotum with the descent of the testicles to become the tunica vaginalis.

PROCTITIS. Inflammation of the anus and rectum.

PROCTOSCOPE. An instrument consisting of a thin tube with a light source, used to examine the inside of the rectum.

PROCTOSCOPY. A procedure in which a thin tube containing a camera and a light is inserted into the rectum so the doctor can visually inspect it.

PRODROME. Symptom(s) experienced prior to the onset of a disease. For example, visual disturbances may precede and signal the onset of a migraine headache.

PROGESTERONE. A female hormone that acts on the inner lining of the uterus and prepares it for implantation of the fertilized egg.

PROGESTIN. A synthetic or natural drug that acts on the uterine lining.

PROGNOSIS. The predicted outcome of a disease.

PROGRESSIVE. A term that refers to a disease that gets worse over time.

PROGRESSIVE SUPRANUCLEAR PALSY. A rare disease that gradually destroys nerve cells in the parts of the brain that control eye movements, breathing, and muscle coordination, which causes palsy, or paralysis.

PROHORMONES. A physiologically inactive precursor of a hormone.

PROJECTIVE TEST. A type of psychological test that assesses a person's thinking patterns, observational ability, feelings, and attitudes on the basis of responses to ambiguous test materials. It is not intended to diagnose psychiatric disorders.

PROKINETIC. A drug that works to speed up the emptying of the stomach and the motility of the intestines.

PROLACTIN. A hormone that helps the breast prepare for milk production during pregnancy.

PROLACTINOMA. A benign (noncancerous) tumor of the pituitary gland that secretes the hormone prolactin.

PROLAPSED UMBILICAL CORD. Occurs when the cord falls into the birth canal, and may even hang out of the mother's vagina. This can cause compression of the cord and lead to decreased oxygen and blood flow to the fetus.

PROLAPSED UTERUS. A uterus that has slipped out of place, sometimes protruding down through the vagina.

PROLIFERATIVE RETINOPATHY. Retinopathy with the growth of new blood vessels (neovascularization).

PRONATION. The lowering or descending of the inner edge of the foot by turning the entire foot outwards.

PROPENSITY. A greater risk for developing a disease.

PROPHYLACTIC. Referring to medications or other treatments given to prevent disease.

PROPHYLAXIS. Preventive. Antibiotic prophylaxis is the use of antibiotics to prevent a possible infection.

PROPIONIBACTERIUM ACNES. Skin bacteria that infect sebaceous follicles, causing acne.

PROPRANOLOL (INDERAL). Medication commonly prescribed to treat high blood pressure; is a beta-adrenergic blocker and can also be used to treat irregular heartbeat, heart attack, migraine, and tremors.

PROPRIOCEPTIVE. Pertaining to proprioception, or the awareness of posture, movement, and changes in equilibrium and the knowledge of position, weight, and resistance of objects as they relate to the body.

PROSTAGLANDIN. A group of molecules that exert local effects on a variety of processes including fluid balance, blood flow, and gastrointestinal function.

PROSTAGLANDIN ANALOGUE. A class of drugs that are similar in structure and function to prostaglandin.

PROSTATE. A donut-shaped gland below the bladder in men that contributes to the production of semen.

PROSTATE GLAND. The gland surrounding the male urethra just below the base of the bladder. It secretes a fluid that constitutes a major portion of the semen.

PROSTATE–SPECIFIC ANTIGEN (PSA). A protein made by the cells of the prostate that is increased by both BPH and prostate cancer.

PROSTHESIS. A synthetic replacement for a missing part of the body such as a knee or a hip.

PROSTHETIC TOOTH. The final tooth that is held in place by the dental implant anchor.

PROSTHETICS. Mechanical devices that replace missing body parts.

PROSTHETIST. A health care professional who is skilled in making and fitting artificial parts (prosthetics) for the human body.

PROTEASE INHIBITORS. The second major category of drug used to treat AIDS that works by suppressing the replication of the HIV virus.

PROTEIN. A substance produced by a gene that is involved in creating the traits of the human body, such as hair and eye color, or is involved in controlling the basic functions of the human body, such as control of the cell cycle.

PROTEINURIA. The presence of protein in the urine exceeding normal levels.

PROTHROMBIN. A type of protein called a glycoprotein that is converted to thrombin during the clotting process.

PROTHROMBIN TIME. A blood test that determines how quickly a person's blood will clot.

PROTOPORPHYRIN. A precursor molecule to the porphyrin molecule.

PROTOPORPHYRIN IX. Protoporphyrin IX is a protein. The measurement of this protein is useful for the assessment of iron status. Hemoglobin consists of a complex of a protein plus heme. Heme consists of iron plus protoporphyrin IX. Normally, during the course of red blood cell formation, protoporphyrin IX acquires iron, to generate heme, and the heme becomes incorporated into hemoglobin. However, in iron deficiency, protophoryrin IX builds up.

PROTOZOA. (Plural form of protozoan) Single-celled organisms (not bacteria) of which about 30 kinds cause disease in humans.

PROXIMAL TUBULE. The portion of the kidney tubule that lies closest to the point at which fluid from the blood enters the tubule.

PRURICEPTORS. Nerve endings specialized to perceive itching sensations.

PRURITUS. The medical term for itching.

PRUSSIAN BLUE. The common name of potassium ferric hexacyanoferrate, a compound approved in the United States for treatment of thallium poisoning. Prussian blue gets its name from the fact that it was first used by artists in 1704 as a dark blue pigment for oil paints. It has also been used in laundry bluing and fabric printing.

PSEUDODEMENTIA. Depression with symptoms resembling those of dementia. The term "dementia of depression" is now preferred.

PSEUDOGYNECOMASTIA. Enlargement of the male breast caused solely by fat accumulation. It is also called lipomastia.

PSEUDOPHAKIC BULLOUS KERATOPATHY. Painful swelling of the cornea occasionally occurring after surgery to implant an artificial lens in place of a lens affected by cataract.

PSEUDOXANTHOMA ELASTICUM. A hereditary disorder of the connective, or elastic, tissue marked by premature aging and breakdown of the skin and degeneration of the arteries that leads to hemorrhages.

PSORALEN. A family of photosensitizing chemicals that can be found in lemons, celery, and other plants. Chemically synthesized versions are used to augment the effects of UVA light treatments.

PSORIASIS. A common recurring skin disease that is marked by dry, scaly, and silvery patches of skin that appear in a variety of sizes and locations on the body.

PSORIATIC ARTHRITIS MUTILANS. A severe form of psoriatic arthritis that destroys the joints of the fingers and toes and causes the bones to fuse, leaving patients with gnarled and club-like hands and feet.

PSYCHIATRIST. A medical doctor who has completed specialized training in the diagnosis and treatment of mental illness.

PSYCHOACTIVE. Substance that effects emotional and psychological perception in the brain.

PSYCHOACTIVE DRUGS. Any drug that affects the mind or behavior. There are five main classes of psychoactive drugs: opiates and opioids (e.g. heroin and methadone); stimulants (e.g. cocaine, nicotine), depressants (e.g. tranquilizers, antipsychotics, alcohol), hallucinogens (e.g. LSD), and marijuana and hashish.

PSYCHODYNAMIC PSYCHOTHERAPY. A less intensive form of insight-oriented therapy than psychoanalysis that typically involves greater interaction between therapist and patient than classical psychoanalysis.

PSYCHODYNAMIC THERAPY. A therapeutic approach that assumes dysfunctional or unwanted behavior is caused by unconscious, internal conflicts and focuses on gaining insight into these motivations.

PSYCHOGENIC. Referring to a disorder associated with mental or emotional conflict. At one time most stuttering was considered psychogenic, but recent research indicates that psychogenic stuttering is the least common form.

PSYCHOLOGICAL. Pertaining to the mind, its mental processes, and its emotional makeup.

PSYCHOLOGICAL TESTS. Written, verbal, or visual tasks that assess psychological functioning, intelligence, and/or personality traits.

PSYCHOLOGIST. A mental health professional who treats mental and behavioral disorders by support and insight to encourage healthy behavior patterns and personality growth. Psychologists also study the brain, behavior, emotions, and learning.

PSYCHOMOTOR AGITATION. Disturbed physical and mental processes (e.g., fidgeting, wringing of hands, racing thoughts); a symptom of major depressive disorder.

PSYCHOMOTOR RETARDATION. Slowed physical and mental processes (e.g., slowed thinking, walking, and talking); a symptom of major depressive disorder.

PSYCHOPATHOLOGY. A mental disorder or illness, such as schizophrenia, personality disorder, or major depressive disorder.

PSYCHOSIS. A serious mental disorder characterized by defective or lost contact with reality often with hallucinations or delusions.

PSYCHOSOCIAL. A term referring to the mind's ability to, consciously or unconsciously, adjust and relate the body to its social environment.

PSYCHOSOMATIC. Referring to physical symptoms that are caused or significantly influenced by emotional factors. Some doctors regard couvade syndrome as a psychosomatic condition.

PSYCHOSURGERY. Brain surgery performed to alleviate chronic psychological conditions such as obsessive-compulsive disorder (OCD), depression, and bipolar disorder.

PSYCHOTHERAPY. The treatment of mental and behavioral disorders by support and insight to encourage healthy behavior patterns and personality growth.

PSYCHOTIC DISORDER. A mental disorder characterized by delusions, hallucinations, or other symptoms of lack of contact with reality. The schizophrenias are psychotic disorders.

PSYLLIUM HYDROPHILIC MUCILLOID. A plant material contained in some laxatives.

PUBERTY. Point in development when the gonads begin to function and secondary sexual characteristics begin to appear.

PUBIS. The anterior portion of the pelvis located in the anterior abdomen.

PULMONARY. Referring to the lungs and respiratory system.

PULMONARY ANGIOGRAPHY. An x-ray study of the lungs, performed by insertion of a catheter into a vein, through the heart, and into the pulmonary artery. Pulmonary angiography is performed to evaluate blood circulation to the lungs. It is also considered the most accurate diagnostic test for detecting a pulmonary embolism.

PULMONARY ARTERY. The blood vessel that delivers blood from the heart to the lungs.

PULMONARY EDEMA. A problem caused when fluid backs up into the veins of the lungs. Increased pressure in these veins forces fluid out of the vein and into the air spaces (alveoli). This interferes with the exchange of oxygen and carbon dioxide in the alveoli.

PULMONARY EMBOLISM. An obstruction of a blood vessel in the lungs, usually caused by a blood clot that blocks a coronary artery. Pulmonary embolism can be very serious and, in some cases, fatal.

PULMONARY FIBROSIS. A scarring process that is the end result of many forms of long-lasting lung disease.

PULMONARY FUNCTION TEST. A test that measures the capacity and function of the lungs as well as the blood's ability to carry oxygen. During the test, the patient breathes into a device called a spirometer.

PULMONARY HYPERTENSION. High blood pressure in the veins and arteries of the lungs.

PULMONARY NODULE. A lesion surrounded by normal lung tissue. Nodules may be caused by bacteria, fungi, or a tumor (benign or cancerous).

PULMONARY REHABILITATION. A program to treat COPD, which generally includes education and counseling, exercise, nutritional guidance, techniques to improve breathing, and emotional support.

PULMONARY VALVE. The heart valve that is positioned between the right ventricle and the opening into the pulmonary artery.

PULMONIC VALVE. A fold in the pulmonary artery that directs blood to the lungs. It may be transferred to replace a severely diseased aortic valve during heart valve replacement surgery for aortic stenosis.

PULP. The soft innermost layer of a tooth that contains its blood vessels and nerves.

PULP CHAMBER. The area within the tooth occupied by dental pulp.

PULPITIS. Inflammation of the pulp of a tooth that involves the blood vessels and nerves.

PULSE OXIMETRY. The noninvasive monitoring or determination of oxygen-hemoglobin saturation of the blood.

PUNCH BIOPSY. A method of obtaining skin samples under local anesthesia using a surgical skin punch.

PUNCTUM. Tiny opening at the inner corners of the upper and lower lids. The area for the beginning of tear drainage.

PUNCTURE. An injury caused by a sharp, narrow object deeply penetrating the skin.

PUPIL. The opening in the center of the iris that allows light to pass through to the retina.

PURGING. The use of vomiting, diuretics, or laxatives to clear the stomach and intestines after a binge.

PURIFIED PROTEIN DERIVATIVE (PPD). An extract of tubercle bacilli that is injected into the skin to find out whether a person presently has or has ever had tuberculosis.

PURINE. A white crystalline substance that is one of the building blocks of DNA. Uric acid is produced when purine is broken down in the body.

PURKINJE'S CELLS. Large branching cells of the nervous system.

PURPURA. A skin discoloration of purplish or brownish red spots caused by bleeding from broken capillaries.

PURULENT. Consisting of or containing pus.

PUS. A generally viscous, yellowish–white fluid formed in infected tissue, consisting of white blood cells, cellular debris, and dead tissue.

PUSTULE. A small elevation of the skin containing pus or cloudy tissue fluid.

PUVA. A type of phototherapy that combines the oral or topical photosensitizing chemical psoralen with long-wave ultraviolet light A (UVA).

PYELONEPHRITIS. Bacterial inflammation of the upper urinary tract.

PYLORUS. The ring of muscle that controls the passage of material from the stomach into the small intestine.

PYODERMA. A pus-containing skin infection, such as impetigo, caused by *Staphylococcus* or group A *Streptococcus* bacteria.

PYOGENIC. Capable of generating pus. *Streptococcus*, *Staphocococcus*, and bowel bacteria are the primary pyogenic organisms.

PYOGENIC ARTHRITIS. Another name for infectious arthritis. Pyogenic means that pus is formed during the disease process.

PYRETHRIN, PYRETHROID. Naturally-occurring insecticide extracted from chrysanthemum flowers. It paralyzes lice so that they cannot feed.

PYREXIA. A medical term denoting fevers.

PYRIDOSTIGMINE BROMIDE (MESTINON). An anticholinesterase drug used in treating myasthenia gravis.

PYROGEN. A chemical circulating in the blood that causes a rise in body temperature.

PYROMANIA. An impulse control disorder in which one sets fires.

Q

Q-FEVER. A disease that is marked by high fever, chills and muscle pain. It is seen in North America, Europe, and parts of Africa. It may be spread by drinking raw milk, or by tick bites.

QI. Basic life energy, according to traditional Chinese medicine.

QRS. A pattern seen in an electrocardiogram that indicates the pulses in a heart beat and their duration. Variations from a normal QRS pattern indicate heart disease.

QUADRANTECTOMY. Removal of a quadrant, or about a quarter of the breast.

QUADRICEPS, HIP FLEXORS, HAMSTRINGS. Major muscles in the thigh area that affect knee mechanics.

QUADRIPLEGIA. Paralysis of all four limbs.

QUADRIVALENT VACCINE. A vaccine that protects against four pathogens.

QUANTIFIABLE. Can be expressed as a number. The results of quantifiable psychological tests can be translated into numerical values, or scores.

QUININE. One of the first treatments for malaria, quinine is a natural product made from the bark of the Cinchona tree. It was popular until being superseded by the development of chloroquine in the 1940s. In the wake of widespread chloroquine resistance, however, it has become popular again. Quinine, or its close relative quinidine, can be given intravenously to treat severe *Falciparum* malaria.

QV. Quantum vacuum, a theory coined by physicists, which defines the interactions of energy that combine to form reality.

R

RABIES. A rare but serious disease caused by a virus carried in saliva. It is transmitted when an infected animal bites a person.

RACHITIC ROSARY. Beadlike bumps present at the junction of the ribs with their cartilages; often seen in children with rickets.

RADIAL ARTERY. An artery located in the arm and used for bypass grafts.

RADIAL KERATOTOMY (RK). A surgical procedure involving the use of a diamond–tipped blade to make several spoke–like slits in the peripheral (non–viewing) portion of the cornea to improve the focus of the eye and correct myopia by flattening the cornea.

RADIATION THERAPY. Use of radioisotopes to kill tumor cells. Applied externally through a beam of x rays, intraoperatively (during surgery), or deposited internally by implanting radioactive seeds in tumor tissue.

RADICAL PROSTATECTOMY. Surgical removal of the entire prostate, a common method of treating prostate cancer.

RADICAL RESECTION. Surgical resection that takes the blood supply and lymph system supplying the organ along with the organ.

RADICULAR. Pain that is caused by the root of a nerve.

RADICULOPATHY. Sometimes referred to as a pinched nerve, it refers to compression of the nerve

root–the part of a nerve between vertebrae. This compression causes pain to be perceived in areas to which the nerve leads.

RADIO WAVES. Electromagnetic energy of the frequency range corresponding to that used in radio communications, usually 10,000 cycles per second to 300 billion cycles per second. Radio waves are the same as visible light, x rays, and all other types of electromagnetic radiation, but are of a higher frequency.

RADIOACTIVE ISOTOPE. One of two or more atoms with the same number of protons but a different number of neutrons with a nuclear composition. In nuclear scanning, radioactive isotopes are used as a diagnostic agent.

RADIOCONTRAST AGENTS. Dyes administered to a patient for the purposes of a radiologic study.

RADIOFREQUENCY ABLATION (RFA). A procedure in which radiofrequency waves are used to destroy blood vessels and tissues.

RADIOGRAPH. The actual picture or film produced by an x-ray study.

RADIOGRAPHICALLY DENSE. An abundance of glandular tissue that results in diminished anatomic detail on the mammogram.

RADIOGRAPHY. Examination of any part of the body through the use of x rays. The process produces an image of shadows and contrasts on film.

RADIOISOTOPE. An unstable form of an element that gives off radiation to become stable.

RADIOLOGIST. A medical doctor specially trained in radiology (x ray) interpretation and its use in the diagnosis of diseases and injuries.

RADIONUCLIDE. A substance that emits radiation that can be detected by a scanner as the substance disintegrates.

RADIONUCLIDE BONE SCAN. A test that tells if cancer has spread to the bones.

RADIONUCLIDE SCANNING. Diagnostic test in which a radioactive dye is injected into the bloodstream and photographed to display internal vessels, organs and tissues.

RADIOPHARMACEUTICAL. A radioactive pharmaceutical or chemical (usually radioactive iodine or cobalt) used for diagnostic or therapeutic purposes.

RADIOSURGERY. A precise delivery of a large dose of radiation to a targeted area within the brain.

RADIOTHERAPY. The use of ionizing radiation, either as x rays or radioactive isotopes, to treat disease.

RANGE OF MOTION (ROM). The range of motion of a joint from full extension to full flexion (bending) measured in degrees like a circle.

RAPID CYCLING. Four or more manic, hypomanic, mixed, or depressive episodes within a 12-month period.

RAPID EYE MOVEMENT (REM) SLEEP. A phase of sleep during which the person's eyes move rapidly beneath the lids. It accounts for 20–25% of sleep time. Dreaming occurs during REM sleep.

RASH. A spotted, pink or red skin eruption that may be accompanied by itching and is caused by disease, contact with an allergen, food ingestion, or drug reaction.

RAYNAUD PHENOMENON/RAYNAUD DISEASE. A condition in which blood flow to the body's tissues is reduced by a malfunction of the nerves that regulate the constriction of blood vessels. When attacks of Raynaud's occur in the absence of other medical conditions, it is called Raynaud disease. When attacks occur as part of a disease (as in scleroderma), it is called Raynaud phenomenon.

REACTIVE ARTHRITIS. Another name for Reiter's syndrome.

REACTIVE STRESS TEST. A positive sign of fetal well being. The FHR rises at least 20 beats per minute above the baseline heart rate for at least 20 seconds, occurring at least twice in a 20-minute period.

REBOUND HEADACHE. A type of primary headache caused by overuse of pain relievers. It is also known as analgesic abuse headache.

RECEPTOR. A molecular structure in a cell or on the surface of a cell that allows binding of a specific substance that causes a specific physiologic response.

RECESSIVE GENE. A type of gene that is not expressed as a trait unless inherited by both parents.

RECESSIVE INHERITANCE. A pattern of inheritance where both parents carry the gene responsible for a trait or disease (although they seldom show symptoms). Their offspring will have a 25% chance of having the trait or disease. Recessive inheritance is also responsible for disorders such as hemophilia, where the mother carries the affected gene on the X chromosome and passes it to her son.

RECESSIVE TRAIT. An inherited trait or characteristic that is outwardly obvious only when two copies of the gene for that trait are present.

RECIPIENT. A person who receives an organ transplant.

RECOMBINANT PROTEIN. A manipulated or modified form of a protein which results in the ability to produce the modified protein on a large scale.

RECOMMENDED DIETARY ALLOWANCE (RDA). Guidelines for the amounts of vitamins and minerals necessary for proper health and nutrition established by the National Academy of Sciences in 1989.

RECOMPRESSION. Restoring the elevated pressure of the diving environment to treat decompression sickness and gas embolism by decreasing bubble size.

RECTAL PROLAPSE. Protrusion of the rectal mucous membrane through the anus.

RECTOCELE. Bulging of the rectum into the vaginal wall.

RECTUM. The last few inches of the large intestine that store waste until it is eliminated from the body through the anus.

RECURRENT ABDOMINAL PAIN (RAP). Functional abdominal pain; stomachaches in children that recur at least once a month and that are not caused by an underlying medical condition.

RECURRENT CORNEAL EROSION (RCE). Repeated erosion of the cornea. May be a result of inadequate healing of a previous abrasion.

RECURRENT LARYNGEAL NERVE. One of two offshoots of the vagus nerve that connect to the larynx. It is located below the larynx.

RECURRENT ULCER. Peptic ulcers that flare up after healing. They may be caused a helicobacter pylori bacterial infection and are treated with a combination of antibiotics and gastric acid reducing medications, like proton pump inhibitors.

RED BLOOD CELL (RBC). Cell that contains hemoglobin (the molecule that transports oxygen) and help remove wastes from tissues throughout the body.

RED BLOOD CELL INDICES. Measurements that describe the size and hemoglobin content of red blood cells.

RED CELL DISTRIBUTION WIDTH (RDW). A measure of the variation in size of red blood cells.

REDUCIBLE HERNIA. A hernia that can be gently pushed back into place or that disappears when the person lies down.

REED-STERNBERG CELLS. Cancerous cells that, when present in the body, are indicative of Hodgkin's lymphoma.

REFERRED PAIN. The presence of pain in an area other than where it originates.

REFLEX. An involuntary response to a particular stimulus.

REFLEX SEIZURE. Seizure brought on by specific sensory stimuli.

REFLEXOLOGY. Belief that reflex areas in the feet correspond to every part of the body, including organs and glands, and that stimulating the correct reflex area can affect the body part.

REFLUX. An abnormal backward or return flow of a fluid.

REFLUX ESOPHAGITIS. Inflammation of the lower esophagus caused by the backflow of stomach contents.

REFRACTION. The bending of light rays as they pass from one medium through another. Used to describe the action of the cornea and lens on light rays as they enter they eye. Also used to describe the determination and measurement of the eye's focusing system by an optometrist or ophthalmologist.

REFRACTIVE ERROR. The inability of the eye to properly focus light due to an irregularly shaped cornea, resulting in blurry vision, nearsightedness, farsightedness, or astigmatism.

REFRACTIVE SURGERY. A surgical procedure that corrects visual defects by permanently changing the shape of the cornea.

REGRESSION. A return to earlier, particularly infantile, patterns of thought and behavior.

REGURGITATION. Flow of material back up the esophagus and into the throat or lungs.

REHYDRATION. The restoration of water or fluid to a body that has become dehydrated.

REITER'S SYNDROME. A group of symptoms that includes arthritis, inflammation of the urethra, and conjunctivitis, and develops as a late complication of infection with *Shigella flexneri*. The syndrome was first described by a German doctor named Hans Reiter in 1918.

REJECTION. An immune response that occurs when a transplanted organ is viewed as a foreign substance by the body. If left untreated, rejection can lead to organ failure and even death.

RELAPSE. A recurrence of symptoms after a period of improvement or recovery.

RELAPSING-REMITTING. A pattern of symptoms of multiple sclerosis in which symptomatic attacks occur that last 24 hours or more, followed by complete or almost complete improvement.

RELAXATION RESPONSE. The human body's response to relaxation techniques, during which metabolism and stress levels decrease and immune response increases.

RELAXATION TECHNIQUE. A technique used to relieve stress. Exercise, biofeedback, hypnosis, and meditation are all effective relaxation tools. Relaxation techniques are used in cognitive-behavioral therapy to teach patients new ways of coping with stressful situations.

REM LATENCY. After a person falls asleep, the amount of time it takes for the first onset of REM (rapid eye movement) sleep.

REMEDY ANTIDOTE. Certain foods, beverages, prescription medications, aromatic compounds, and other environmental elements that counteract the efficacy of homeopathic remedies.

REMISSION. A disappearance of a disease as a result of treatment. Complete remission means that all disease is gone. Partial remission means that the disease is significantly improved by treatment, but residual traces of the disease are still present.

REMODELING. The ongoing process of bone formation and breakdown that results in healthy bone development.

RENAL. Relating to the kidneys, from the Latin word *renes*.

RENAL AGENESIS. Failure of the fetal kidneys to form. Oligohydramnios usually associated with absence of both kidneys.

RENAL ARTERY ANEURYSM. An aneurysm relating to, involving, or located in the region of the kidneys.

RENAL ARTERY STENOSIS. Narrowing or constriction of the artery that supplies the kidney with blood.

RENAL CELL CARCINOMA. Cancer of the kidney.

RENAL DISEASE. Kidney disease.

RENAL FAILURE. Disorder characterized by the kidney's inability to filter wastes from the blood. It may be acute (occuring suddenly and usually reversable) or chronic (developing slowly over time as a result of permanent damage).

RENAL ULTRASOUND. A painless and non-invasive procedure in which sound waves are bounced off the kidneys. These sound waves produce a pattern of echoes that are then used by the computer to create pictures of areas inside the kidney (sonograms).

RENIN. An enzyme produced in the kidneys that controls the activation of the hormone angiotensin, which stimulates the adrenal glands to produce aldosterone.

REPERFUSION THERAPY. Restoration of blood flow to an organ or tissue; following a heart attack, quickly opening blocked arteries to reperfuse the heart muscles to minimize damage.

REPETITIVE STRESS INJURY; REPETITIVE STRAIN INJURY (RSI). Any of various musculoskeletal disorders—such as tendonitis or carpal tunnel syndrome—that are caused by cumulative damage to muscles, tendons, ligaments, nerves, or joints from highly repetitive movements, such as of the hand, wrist, arm, or shoulder.

REPRESENTATIVE SAMPLE. A random sample of people that adequately represents the test-taking population in age, gender, race, and socioeconomic standing.

REPRESSION. A unconscious psychological mechanism in which painful or unacceptable ideas, memories, or feelings are removed from conscious awareness or recall.

REPRODUCTIVE ORGANS. The group of organs (including the testes, ovaries, and uterus) whose purpose is to produce a new individual and continue the species.

RESECT; RESECTION. To remove surgically.

RESECTABLE CANCER. A tumor that can be surgically removed.

RESERPINE (SERPASIL). A drug prescribed for high blood pressure.

RESERVOIR. A population in which a virus is maintained without causing serious illness to the infected individuals.

RESIDUE. Traces that remain after most of the rest of the material is gone.

RESORBED. Absorbed by the body because of lack of function. This happens to the jawbone after tooth loss.

RESPIRATION. Respiration is the process by which nutrients (specifically sugar, or glucose) and oxygen are taken in to a cell; chemical reactions take place; energy is produce and stored; and carbon dioxide and wastes are given off.

RESPIRATORY. Referring to breathing in and breathing out, and the function of the lungs.

RESPIRATORY DISTRESS. A condition in which patients with lung disease are not able to get enough oxygen.

RESPIRATORY DISTRESS SYNDROME (RDS). Condition in which a premature infant with immature lungs does not develop surfactant, a protective film that helps air sacs in the lungs to stay open. RDS is the most common problem seen in premature infants.

RESPIRATORY TRACT. The air passages from the nose to the air sacs of the lungs, including the pharynx, larynx, trachea, and bronchi.

RESPITE CARE. Temporary care of a patient to provide parents or other caregivers with a period of physical, mental, and emotional rest.

RESTENOSIS. The narrowing of a blood vessel after it has been opened, usually by balloon angioplasty.

RESTLESS LEGS SYNDROME (RLS). A neurological disorder characterized by aching, burning, or creeping sensations in the legs and an urge to move the legs, often resulting in insomnia.

RESUSCITATION. Reviving an unconscious person or restoring breathing.

RETAINER. An orthodontic appliance that is worn to stabilize teeth in a new position.

RETENTION TREATMENT STAGE. The passive treatment period following orthodontic treatment, when retainers may be used to stabilize the teeth.

RETICULOCYTE. An early, immature form of a red blood cell. Over time, the reticulocyte develops to become a mature, oxygen-carrying red blood cell.

RETINA. The inner, light-sensitive layer of the eye containing rods and cones; transforms the image it receives into electrical messages sent to the brain via the optic nerve.

RETINAL DETACHMENT. A serious vision disorder in which the light-detecting layer of cells inside the eye (retina) is separated from its normal support tissue and no longer functions properly.

RETINAL HEMORRHAGE. Bleeding in the back of the eye.

RETINOBLASTOMA. A hereditary malignant tumor of the retina that develops during childhood.

RETINOIC ACID. Vitamin A_1 acid which is used topically to treat acne.

RETINOID. A synthetic vitamin A derivative used in the treatment of a variety of skin disorders.

RETINOL. Another name for vitamin A.

RETINOPATHY OF PREMATURITY. A condition in which the blood vessels in a premature infant's eyes do not develop normally, and can, in some cases, result in blindness.

RETINOSCOPE. An instrument for determining the state of refraction of the eye by illuminating the retina with a mirror.

RETRACTOR. An instrument used during surgery to hold an incision open and pull back underlying layers of tissue.

RETROGRADE EJACULATION. A condition in which the semen spurts backward into the bladder.

RETROGRADE MENSTRUATION. Menstrual flow that travels into the body cavity rather than being expelled through the uterus.

RETROGRADE PYELOGRAM. A pyelography or x-ray technique in which a dye is injected into the kidneys through the ureters.

RETROPUBIC URETHROPEXY. A generic term for the Burch procedure and its variants that treat mild stress incontinence by stabilizing the urethra with retropubic surgery.

RETROVIRUS. A family of RNA viruses containing a reverse transcriptase enzyme, which allows the viruses' genetic information to become part of the genetic information of the host cell upon replication.

REVERSE TRANSCRIPTION-POLYMERASE CHAIN REACTION; RT-PCR. A method of polymerase-chain-reaction amplification of nucleic acid sequences that uses RNA as the template for transcribing the corresponding DNA using reverse transcriptase.

REYE'S SYNDROME. A life-threatening disease that affects the liver and the brain and sometimes occurs after a viral infection, such as flu or chickenpox. Children or teenagers who are given aspirin for flu or chickenpox are at increased risk of developing Reye's syndrome.

RH (RHESUS) FACTOR. An antigen present in the red blood cells of 85% of humans. A person with Rh factor is Rh positive (Rh+); a person without it is

Rh negative (Rh-). The Rh factor was first identified in the blood of a rhesus monkey.

RH BLOOD INCOMPATIBILITY. A blood type problem between mother (who is Rh negative) and baby (who is Rh positive), making the immune system of the mother attack her unborn baby. During delivery of the first pregnancy, the mother's immune system becomes sensitive to the Rh positive blood of the baby. The mother's system may then attack later pregnancies and cause severe illness or death to those babies.

RH BLOOD TYPE. Blood type based on the presence or absence of the D antigen on the red blood cells.

RH DISEASE. The Rh factor is a genetically determined antigen on red blood cells that produce immune responses. If an Rh-negative woman is pregnant with an Rh-positive fetus, her body will produce antibodies against the fetus's blood, causing Rh disease.

RH NEGATIVE. Lacking the Rh factor, genetically determined antigens in red blood cells that produce immune responses.

RH SENSITIZATION. A woman with a negative blood type (Rh negative) who has produced antibodies against her fetus with a positive blood type (Rh positive). The mother's body considered the fetal blood cells a foreign object and mounted an immune attack on it. Rh immune globulin (RhoGAM) is a vaccine that must be given to a woman after an abortion, miscarriage, or prenatal tests in order to prevent sensitization to Rh disease.

RHABDOID. Rod- or wand-shaped, like the first stage of the threadworm larva.

RHABDOVIRUS. A type of virus named for its rod- or bullet-like shape. The rabies virus belongs to a family of viruses called Rhabdoviridae.

RHEUMATIC DISEASE. A type of disease involving inflammation of muscles, joints, and other tissues.

RHEUMATIC FEVER. A disease that causes inflammation in various body tissues. Rare in most developed countries, but reported to be on the increase in parts of the United States. Joint inflammation occurs, but more serious is the frequency with which the disease permanently damages the heart. The nervous system may also be affected, causing Sydenham's chorea.

RHEUMATIC HEART DISEASE. A condition caused by a streptococcus infection which can result in permanent heart damage.

RHEUMATOID ARTHRITIS. A joint disease of unknown origins that may begin at an early age, causing deformity and loss of function in the joints.

RHEUMATOID FACTOR (RF). An antibody present in the blood serum of many individuals affected by rheumatoid arthritis.

RHEUMATOLOGIST. Physician specializing in the diagnosis and treatment of arthritis and related conditions.

RHEUMATOLOGY. The branch of medicine that specializes in the diagnosis and treatment of disorders affecting the muscles and joints.

RHINITIS. An inflammation of the mucous membranes that line the nasal passages.

RHINOPHYMA. Long-term swelling and overgrowth in skin tissue of the nose that leaves it with a knobby bulb-like look.

RHINOPLASTY. Plastic surgery of the nose to repair or change the shape of the nose.

RHINORRHEA. A name for the common cold.

RHINOVIRUS. A virus that infects the upper respiratory system and causes the common cold.

RHYTHM METHOD. The oldest method of contraception, in which partners periodically refrain from having sex during ovulation. This method has a high failure rate.

RHYTIDECTOMY. It literally means "wrinkle excision." It is another term for face lift surgery.

RIBAVIRIN. A drug that is used to combat viral infections.

RICKETS. A condition caused by the dietary deficiency of vitamin D, calcium, and usually phosphorus, seen primarily in infancy and childhood, and characterized by abnormal bone formation.

RICKETTSIA. A rod-shaped infectious microorganism that can reproduce only inside a living cell. Scrub typhus is a rickettsial disease.

RIGHT-HEART CARDIAC CATHERIZATION. A medical procedure during which a physician threads a catheter into the right side of the heart to measure the blood pressure in the right side of the heart and the pulmonary artery. The right heart's pumping ability can also be evaluated.

RINGWORM. A fungal infection of the skin, usually known as tinea corporis.

RINNE TEST. A hearing test using a vibrating tuning fork which is held near the ear and held at the back of the skull.

ROD. Photoreceptor that is highly sensitive to low levels of light and transmits images in shades of gray.

ROLFING. Based on the belief that proper alignment of various parts of the body is necessary for physical and mental health, rolfing uses deep tissue massage and movement exercises in an attempt to bring the body into correct alignment.

ROOT CANAL. The space within a tooth that runs from the pulp chamber to the tip of the root.

ROOT CANAL TREATMENT. The process of removing diseased or damaged pulp from a tooth, then filling and sealing the pulp chamber and root canals.

RORSCHACH TEST. A well–known projective test that requires the patient to describe what he or she sees in each of 10 inkblots. It is named for the Swiss psychiatrist who invented it.

ROSACEA. A chronic skin disease characterized by persistent redness of the skin and periodic outbreaks of pustules, usually affecting the middle third of the face.

ROSE SPOTS. Small slightly raised reddish pimples that are a distinguishing feature of typhoid or paratyphoid infection.

ROTABLATION. A nonsurgical technique for treating diseased arteries in which a special catheter with a diamond-coated tip is guided to the point of narrowing in the artery. The catheter tip spins at high speed and grinds away the blockage or plaque on the artery walls.

ROTAVIRUS. Any virus of the genus *Rotavirus,* some of which cause gastroenteritis.

ROULEAUX. The stacking up of red blood cells, caused by extra or abnormal proteins in the blood that decrease the normal distance red cells maintain between each other.

ROUNDWORM. Any round-bodied unsegmented worm as distinguished from a flatworm. Also called a nematode, they look similar to the common earthworm.

RUBELLA. A contagious viral disease that is milder than typical measles but is damaging to the fetus when it occurs early in pregnancy. Also called German measles.

RUPTURE. A tear or break in body tissue of an organ.

RUSSELL'S SIGN. Scraped or raw areas on the patient's knuckles, caused by self-induced vomiting.

S

SACCULAR ANEURYSM. A type of aneurysm that resembles a small sack of blood attached to the outer surface of a blood vessel by a thin neck.

SACRAL NERVES. The five pairs of nerves that arise from the lowermost segments of the spinal cord and control bladder, bowel, and pelvic functions. Stimulation of the sacral nerves by an implanted device is a newer treatment for urinary incontinence.

SACROCOCCYGEAL TERATOMA (SCT). A tumor occurring at the base of the fetus's tailbone.

SACRUM. Posterior bony wall of the pelvis.

SADISM. Sexual arousal through inflicting pain on another person.

SALICYLATES. A group of drugs that includes aspirin and related compounds. Salicylates are used to relieve pain, reduce inflammation, and lower fever.

SALICYLIC ACID. An agent prescribed in the treatment of hyperkeratotic skin conditions and fungal infections.

SALINE. A salt solution in water. Normal saline has the same salt concentration as the body, 0.9%.

SALIVARY DUCT. Tube through which saliva is carried from the salivary gland to the mouth.

SALIVARY GLAND. Three pairs of glands that secrete into the mouth and aid digestion.

SALMONELLOSIS. Food poisoning; an infection by bacteria of the genus *Salmonella* that usually causes severe diarrhea and may be transmitted to the fetus.

SALPINGITIS. Inflammation of the fallopian tube.

SALVAGE THERAPY. Treatment measures taken late in the course of a disease after other therapies have failed. It is also known as rescue therapy.

SAMANA. Life sustaining energy of the smaller intestine; the fourth of the five airs of Ayurvedic philosophy; the life force governing side-to-side motion.

SAPHENOUS VEIN. A long vein in the thigh or calf commonly used for bypass grafts.

SARCOIDOSIS. A chronic disease that causes formation of abnormal areas containing inflammatory cells, called granulomas, in any organ or tissue; in

the heart, large areas of the heart muscle can be involved, causing cardiomyopathy.

SARCOMA. A type of cancer that originates from connective tissue such as bone or muscle.

SARGRAMOSTIM. A medication made from yeast that stimulates WBC production. It is sold under the trade names Leukine and Prokine.

SATURATED FAT. Found mainly in meat and dairy products but also in vegetable sources such as some nuts, seeds, and avocados.

SCABIES. A contagious parasitic skin disease characterized by intense itching.

SCHEMAS. Fundamental core beliefs or assumptions that are part of the perceptual filter people use to view the world. Cognitive-behavioral therapy seeks to change maladaptive schemas.

SCHEUERMANN'S DISEASE. Juvenile kyphosis due to damaged bone in the spinal vertebrae.

SCHIZOAFFECTIVE DISORDER. Schizophrenic symptoms occurring concurrently with a major depressive and/or manic episode.

SCHIZOPHRENIA. A severe mental illness in which a person has difficulty distinguishing what is real from what is not real. It is often characterized by hallucinations, delusions, and withdrawal from people and social activities.

SCHIZOPHRENIFORM DISORDER. A short-term variation of schizophrenia that has a total duration of one to six months.

SCHWANNOMA. A tumor derived from the cells of the myelin sheath that surrounds many nerve cells.

SCIATICA. Pain that radiates along the sciatic nerve, extending from the buttock down the leg to the foot.

SCINTIGRAM. A nuclear angiogram; a scintigram involves injection of a radioactive substance into the patient's circulatory system. As the substance travels through the body, a special scanning camera takes pictures.

SCINTILLATION OR GAMMA CAMERA. A camera, somewhat like an x-ray machine, used to photograph internal organs after the patient has been injected with a radioactive material.

SCLERA. The tough, fibrous, white outer protective covering that surrounds the eye.

SCLERODERMA. A disease that first affects the skin and later affects certain internal organs. The first symptoms are the hardening, thickening, and shrinking of the skin.

SCLEROSANT. An irritating solution that stops bleeding by hardening the blood or vein it is injected into.

SCLEROSIS. Hardening.

SCOLIOMETER. A tool for measuring trunk asymmetry; it includes a bubble level and angle measure.

SCOLIOSIS. An abnormal, side-to-side curvature of the spine.

SCOTOMA. An area of lost or depressed vision within the visual field surrounded by an area of normal vision. Survivors of retinoblastoma frequently develop scotomas.

SCREENING. Process through which carriers of a trait may be identified within a population.

SCROTUM. The pouch of skin containing the testes, epididymis, and portions of the spermatic cords.

SCURVY. A nutritional disorder resulting from a deficiency of vitamin C that causes skin bruising and hemorrhages.

SEALANT. A thin plastic substance that is painted over teeth as an anti-cavity measure to seal out food particles and acids produced by bacteria.

SEALED RADIOACTIVE SOURCES. A radioactive source which is contained or sealed within a ribbon, wire, needle, balloon, tube or catheter.

SEASONAL AFFECTIVE DISORDER (SAD). A mood disorder characterized by depression during the winter months.

SEBACEOUS FOLLICLES. Structures in the skin that contain oil-producing glands and hair follicles and which give rise acne.

SEBACEOUS GLANDS. Tiny structures in the skin that produce oil (sebum). If they become plugged, sebum collects inside and forms a nurturing place for germs to grow.

SEBUM. An oily or waxy substance secreted by certain glands in the skin that protects hair and skin against fungi and some bacteria.

SECONDARY GAIN. The social, occupational, or interpersonal advantages that a patient derives from symptoms. A patient's being relieved of his or her

share of household chores by other family members would be an example of secondary gain.

SECONDARY INFECTION. An infection by a microbe that occurs because the body is weakened by a primary infection caused by a different kind of microbe; also called an opportunistic infection.

SECONDARY POLYCYTHEMIA. Secondary polycythemia occurs when the excess of red blood cells is caused by a condition other than polycythemia vera. For example, when low levels of oxygen in the blood stimulate the bone marrow to produce more red blood cells, as in chronic lung disease.

SECONDARY PROGRESSIVE. A pattern of symptoms of multiple sclerosis in which there are relapses and remissions, followed by more steady progression of symptoms.

SECRETION. A substance, such as saliva or mucus, that is produced and given off by a cell or a gland.

SEDATIVE. Medicine that has a calming effect and may be used to treat nervousness or restlessness.

SEDENTARY. Inactivity and lack of exercise; a lifestyle that is a major risk factor for becoming overweight or obese and developing chronic diseases.

SEIZURE. A sudden attack, spasm, or convulsion.

SELECTIVE REDUCTION. Typically referred to in cases of multifetal pregnancy, when one or more fetuses are aborted to preserve the viability of the remaining fetuses and decrease health risks to the mother.

SELECTIVE SEROTONIN REUPTAKE INHIBITORS (SSRIS). A class of antidepressants that work by blocking the reabsorption of serotonin in brain cells, raising the level of the chemical in the brain. SSRIs include Prozac, Zoloft, Luvex, and Paxil.

SELENIUM. A mineral needed in extremely small quantities by the body. Large amounts can be very toxic.

SELF-DELIVERANCE. Another term for assisted suicide, more commonly used in Great Britain than in the United States.

SELF-LIMITED. A disease that runs its course without the need for professional medical treatment.

SEMEN. The thick whitish liquid released from the penis during sexual intercourse. It contains sperm and other secretions.

SEMICIRCULAR CANALS. Structures of the inner ear that help in maintaining balance.

SENESCENCE. Aging.

SENSITIVITY TEST. A test that determines which antibiotics will kill the bacteria that has been isolated from a culture.

SENSORINEURAL HEARING LOSS. Hearing loss caused by damage to the nerves or parts of the inner ear governing the sense of hearing.

SENSORY AWARENESS. Bringing attention to the sensations of tension and/or release in the muscles.

SENSORY DEPRIVATION. A situation where an individual finds himself in an environment without sensory cues. Also, (used here) the act of shutting one's senses off to outside sensory stimuli to achieve hallucinatory experiences and/or to observe the psychological results.

SENSORY INTEGRATION DYSFUNCTION. A neurological disorder in which a person has trouble processing and integrating all the information relayed to the brain by the various senses. Some researchers think that it is a possible cause of selective mutism.

SENSORY NERVES. Nerves that convey impulses from sense organs to the higher parts of the nervous system, including the brain.

SENTINEL LYMPH NODE. The first lymph node to receive lymph fluid from a tumor. If the sentinel node is cancer free, then it is likely that the cancerous cells have not metastasized.

SENTINEL NODE BIOPSY. A newer procedure performed in order to determine whether breast cancer has spread to auxiliary (underarm) lymph nodes.

SEPSIS. An overwhelming infection with effects throughout the body.

SEPTAL. Relating to the ventricular septum, the thin muscle wall dividing the right and left sides of the heart.

SEPTAL DEFECTS. These are holes in the septum, the muscle wall separating the right and left sides of the heart. Atrial septal defects are openings between the two upper heart chambers and ventricular septal defects are openings between the two lower heart chambers.

SEPTAL HEMATOMA. A mass of extravasated blood that is confined within the nasal septum.

SEPTIC. Referring to the presence of infection.

SEPTIC ARTHRITIS. Another name for infectious arthritis.

SEPTIC SHOCK. A life-threatening drop in blood pressure caused by bacterial infection.

SEPTICEMIA. The medical term for blood poisoning, in which bacteria have invaded the bloodstream and circulates throughout the body.

SEPTUM (NASAL). The dividing partition in the nose that separates the two nostrils. It is composed of bone and cartilage.

SEPTUM (VENTRICULAR). That portion of the heart wall that divides the right and left ventricles.

SEQUESTRATION. A process in which the spleen withdraws some normal blood cells from circulation and holds them in case the body needs extra blood in an emergency.

SERIAL CASTING. A series of casts designed to gradually move a limb into a more functional position.

SERIAL MEASUREMENTS. A series of measurements looking for an increase or decrease over time.

SERIAL MONITORING. Monitoring of results of several blood tests over time to detect a pattern of increasing, decreasing, or unchanging values in the blood.

SERIAL X RAYS. A number of x rays performed at set times in the disease progression or treatment intervals. The radiographs will be compared to one another to track changes.

SEROCONVERSION. The development of detectable specific antibodies in a patient's blood serum as a result of infection or immunization.

SEROLOGICAL TESTS. Tests of immune function that are performed using the clear yellow liquid part of blood.

SEROLOGY. The analysis of the contents and properties of blood serum.

SEROSITIS. Inflammation of a serosal membrane. Polyserositis refers to the inflammation of two or more serosal membranes.

SEROTONIN. 5-Hydroxytryptamine; a substance that occurs throughout the body with numerous effects including neurotransmission in the brain. Inadequate amounts of serotonin are implicated in some forms of depression, obsessive-compulsive disorder, and anxiety disorders.

SEROTONIN DOPAMINE ANTAGONIST (SDA). The newer second-generation antipsychotic drugs, also called atypical antipsychotics. SDAs include clozapine (Clozaril), risperidone (Risperdal), and olanzapine (Zyprexa).

SEROTONIN SYNDROME. A group of symptoms caused by severely elevated serotonin levels in the body.

SEROTYPE. Microorganisms differing in the type of surface antigens.

SERTRALINE. An SSRI that is used to treat mental depression and a variety of other disorders.

SERUM (PLURAL, SERA). The clear fluid that separates from blood when the blood is allowed to clot completely. Blood serum can also be defined as blood plasma from which fibrinogen has been removed.

SERUM GASTRIN TEST. A laboratory test that is performed on a blood sample to determine that level of the hormone gastrin. High levels of gastrin indicate the presence a duodenal ulcer or a gastrinoma.

SERUM REAGENTS. Serum is fluid, or the fluid portion of the blood retained after removal of the blood cells and fibrin clot. Reagents are substances added to the serum to produce a chemical reaction.

SEX HORMONES. Hormones that are responsible for sexual characteristics and reproductive functioning.

SEX-LINKED. Refers to genes or traits carried on one of the sex chromosomes, usually the X.

SEX-LINKED GENETIC DISORDER. A disease or disorder caused by a gene mutation located on the X (female) or Y (male) chromosome.

SEXUAL ABUSE. When an individual is forced to engage in sexual activity by use of threats or other fear tactics, or instances in which an individual is physically unable to refuse.

SEXUAL ANHEDONIA. The inability to experience sexual pleasure.

SEXUAL AROUSAL DISORDER. The inhibition of the general arousal aspect of sexual response.

SEXUAL ASSAULT NURSE EXAMINER (SANE). A registered nurse who is trained to collect and document evidence from a sexual assault victim, evaluate and treat for STDs and pregnancy, and refer victims to follow-up medical care and counseling.

SEXUALLY TRANSMITTED DISEASE (STD). A disease that is passed from one person to another through sexual intercourse or other intimate sexual contact; also referred to as a sexually transmitted infection (STI).

SÉZARY SYNDROME. A leukemic phase of CTCL that develops in some patients, characterized by the appearance of malignant T cells in the peripheral blood and

sometimes in the lymph nodes. The syndrome is named for Alfred Sézary (1880-1956), a French dermatologist.

SHARED PSYCHOTIC DISORDER. Also known as folie à deux; shared psychotic disorder is an uncommon disorder in which the same delusion is shared by two or more individuals.

SHAVE BIOPSY. A method of removing a sample of skin lesion so it can be examined by a pathologist. A scalpel or razor blade is held parallel to the skin's surface and is used to slice the lesion at its base.

SHEEP BLOOD AGAR PLATE. A petri dish filled with a nutrient gel containing red blood cells that is used to detect the presence of streptococcal bacteria in a throat culture. Streptococcal bacteria will lyse or break the red blood cells, leaving a clear spot around the bacterial colony.

SHIATSU. Japanese form of acupressure massage.

SHINGLES. A disease caused by an infection with the Herpes zoster virus, the same virus that causes chickenpox. Symptoms of shingles include pain and blisters along one nerve, usually on the face, chest, stomach, or back.

SHOCK. An abnormal condition resulting from low blood volume due to hemorrhage or dehydration. Signs of shock include rapid pulse and breathing, and cool, moist, pale skin.

SHOCK WAVE THERAPY. A method of treating tennis elbow and other musculoskeletal injuries that involves directing bursts of high-pressure sound waves at the affected area.

SHORT BOWEL SYNDROME. A condition in which the bowel is not as long as normal, either because of surgery or because of a congenital defect. Because the bowel has less surface area to absorb nutrients, it can result in malabsorption syndrome.

SHUNT. A passageway (or an artificially created passageway) that diverts blood flow from one main route to another.

SIALOGOGUE. A medication given to increase the flow of saliva.

SIBUTRAMINE. An appetite-suppressing drug that may increase the activity of norepinephrine and serotonin in the brain.

SICK BUILDING SYNDROME. An illness related to MCS in which a person develops symptoms in response to chronic exposure to airborne environmental chemicals found in a tightly sealed building.

SICKLE CELL. A red blood cell that has assumed an elongated shape due to the presence of hemoglobin S.

SICKLE CELL DISEASE. An inherited disorder characterized by a genetic flaw in hemoglobin production. (Hemoglobin is the substance within red blood cells that enables them to transport oxygen.) The hemoglobin that is produced has a kink in its structure that forces the red blood cells to take on a sickle shape, inhibiting their circulation and causing pain. This disorder primarily affects people of African descent.

SIDEROBLASTIC ANEMIA. Disorder in which the body has adequate iron but is unable to incorporate it into hemoglobin.

SIDEROPHILIN. Another name for transferrin.

SIGMOID COLON. The final portion of the large intestine that empties into the rectum.

SIGMOIDOSCOPY. A process of passing a long, hollow tubular instrument through the anus in order to permit inspection, diagnosis, treatment, and imaging, especially of the sigmoid colon.

SILENT REFLUX. An acid reflux problem that does not have marked symptoms but can cause chronic, recurrent respiratory symptoms much like asthma.

SILICOSIS. A progressive disease that results in impairment of lung function and is caused by inhalation of dust containing silica.

SINGLET OXYGEN. A highly reactive form of the oxygen molecule (O_2) formed during PDT that helps to destroy cancer cells by attacking their cell membranes.

SINGLETON. A fetus that develops alone in the uterus.

SINOATRIAL NODE (SAN). The heart's natural pacemaker, a group of cells located in the wall of the right atrium (upper chamber) of the heart near the entry of the superior vena cava, a major vein that carries deoxygenated blood from the upper part of the body to the heart.

SINUS TRACT. A narrow, elongated channel in the body that allows the escape of fluid.

SINUSES. Cavities or hollow areas.

SINUSITIS. Inflammation of the paranasal sinuses because of allergic reactions or viral, bacterial, or functional infections.

SITZ BATH. A hydrotherapy treatment for soaking the pelvic or genital areas.

SJÖGREN'S SYNDROME. A connective tissue disease that hinders the production of tears and other body fluids.

SKELETAL MUSCLES. Muscles that move the skeleton. All of the muscles under voluntary control are skeletal muscles.

SKENE'S GLANDS. These are the glands of the female urethra.

SKIN APPENDAGES. Structures related to the integument such as hair follicles and sweat glands.

SKIN CONTRACTURE. A permanent tightening of the skin that prevents normal movement of the associated body part and that can cause permanent deformity.

SKIN GRAFTING. A technique in which a piece of healthy skin from the patient's body (or a donor's) is used to cover another part of the patient's body that has lost its skin.

SKIN HEMATOMA. Blood from a broken blood vessel that has accumulated under the skin.

SKIN TAG. A small outgrowth of skin tissue that may be smooth or irregular, flesh-colored and benign.

SLEEP APNEA. A condition marked by loud snoring during sleep and periodic episodes of suspended breathing.

SLEEP DISORDER. Any condition that interferes with sleep.

SLEEP LATENCY. The amount of time that it takes to fall asleep. Sleep latency is measured in minutes and is important in diagnosing depression.

SLEEP PARALYSIS. An abnormal episode of sleep in which the patient cannot move for a few minutes, usually occurring on falling asleep or waking up. Often found in patients with narcolepsy.

SLIT LAMP. An instrument that combines a binocular microscope with special lights. It allows an eye doctor to examine the front portion of the eye.

SMALL BOWEL OBSTRUCTION; SBO. An obstruction of the small intestine that prevents the free passage of material; sometimes caused by postoperative adhesions.

SMALL INTESTINE. Consists of three sections: duodenum (nearest the stomach), jejunum, and ileum (nearest the colon or large intestine). Different nutrients are absorbed in different sections of the small intestine.

SMALL-FOR-GESTATIONAL-AGE (SGA). A term used to describe newborns who are below the 10th percentile in height or weight for their estimated gestational age.

SMALLPOX. A highly contagious viral disease characterized by fever, weakness, and skin eruption with pustules that form scabs that slough off leaving scars.

SMEAR. A specimen prepared for microscopic study by spreading the material across a slide and treating it with a specific stain.

SMEAR LAYER. A layer of organic and inorganic material produced on teeth by dental instrumentation that may also contain bacteria and their by-products.

SMOOTH MUSCLES. Muscles that surround the linings of the digestive system, airways, and circulatory system.

SOCIAL PHOBIA. Fear of being judged or ridiculed by others; fear of being embarrassed in public.

SOCIALIZATION. Process by which new members are integrated into a social group.

SOFT PALATE. The structure at the roof of the mouth that separates the mouth and the pharynx.

SOLUTE. Solid substances that are dissolved in liquid in order to make a solution.

SOLUTION-FOCUSED THERAPY. A type of therapy that involves concrete goals and an emphasis on future direction rather than past experiences.

SOMATIC CELLS. All the cells of the body with the exception of the egg and sperm cells.

SOMATIZATION DISORDER. A chronic condition in which psychological stresses are converted into physical symptoms.

SOMATOFORM DISORDER. A category of psychiatric disorder characterized by physical complaints that appear to be medical in origin but that cannot be explained in terms of a physical disease, the results of substance abuse, or by another mental disorder.

SOMNAMBULISM. Another term for sleepwalking.

SONOGRAM. The picture formed by the pattern of echoes from an ultra sound.

SORE. An open wound, bruise, or lesion on the skin.

SPACE MAINTAINER. An orthodontic appliance that is worn to prevent adjacent teeth from moving into the space left by an unerupted or prematurely lost tooth.

SPASM. Sudden, involuntary tightening or tensing of a muscle or a group of muscles.

SPASTIC. A condition in which the muscles are rigid, posture may be abnormal, and fine motor control is impaired.

SPASTICITY. Increased muscle tone, or stiffness, which leads to uncontrolled, awkward movements.

SPECIFICITY. A test's ability to detect only the disease in question.

SPECULUM. An instrument for enlarging the opening of any canal or cavity in order to facilitate inspection of its interior.

SPENT PHASE. A late development in polycythaemia vera leading to failure of the bone marrow and severe anemia.

SPERM. The reproductive cell of the male, which contains genetic information and participates in the act of fertilization of an ovum.

SPERM GRANULOMA. A collection of fluid that leaks from an improperly sealed or tied vas deferens. They usually disappear on their own, but can be drained if necessary.

SPERMATOGENESIS. The process by which sperm develop to become mature sperm, capable of fertilizing an ovum.

SPERMICIDE. A substance that kills sperm.

SPF. Sun protection factor; a number assigned to sunscreens that indicates the amount of UV-B radiation that is required to produce sunburn in the presence of the sunscreen, relative to the amount of UV-B radiation required to burn unprotected skin.

SPHINCTER. A circular band of muscle that surrounds an opening or passage in the body and narrows or closes the opening by contracting.

SPIKE WAVE DISCHARGE. Characteristic abnormal wave pattern in the electroencephalogram that is a hallmark of an area that has the potential of generating a seizure.

SPINA BIFIDA. Myelomeningocele; a congenital defect in which the fetal backbone and spinal canal do not close completely, allowing the spinal cord and its surrounding membranes to protrude.

SPINAL CANAL. The cavity or hollow space within the spine that contains cerebrospinal fluid.

SPINAL CORD. Elongated nerve bundles that lie in the vertebral canal and from which the spinal nerves emerge.

SPINAL FUSION. An operation in which the bones of the lower spine are permanently joined together using a bone graft obtained usually from the hip.

SPINAL STENOSIS. Narrowing of the canals in the vertebrae or around the nerve roots, causing pressure on the spinal cord and nerves.

SPINE. A term for the backbone that includes the vertebrae, disks, and spinal cord as a whole.

SPIRAL CT. Also referred to as helical CT, this method allows for continuous 360-degree x-ray image capture.

SPIROCHETE. A long, slender, coiled-shape bacterium, such as *T. pallidum* that causes syphilis.

SPIROMETER. A device used to measure the volume and rate at which air is inhaled and exhaled by the patient's lungs.

SPIROMETRY. A test using an instrument called a spirometer that shows how difficult it is for an asthmatic individual to breathe. It is used to determine the severity of asthma and to see how well it is responding to treatment.

SPLEEN. An organ located at the left side of the stomach that acts as a reservoir for blood cells and produces lymphocytes and other products involved in fighting infection.

SPLENECTOMY. Surgical removal of the spleen.

SPLENOMEGALY. Abnormal enlargement of the spleen.

SPLINT. A thin piece of rigid material that is sometimes used during nasal surgery to hold certain structures in place until healing is underway.

SPONDYLITIS. An inflammation of the spine.

SPONDYLOSIS. Arthritis of the spine.

SPONTANEOUS PNEUMOTHORAX. Air in the chest cavity that occurs because of disease or other naturally occurring cause. Air and blood together in this space is called a pneumohemothorax.

SPORADIC. Occurring at random or by chance, and not as a result of a genetically determined, or inherited, trait.

SPORE. A dormant form assumed by some bacteria, such as anthrax, that enable the bacterium to survive high temperatures, dryness, and lack of nourishment for long periods of time. Under proper conditions, the spore may revert to the actively multiplying form of the bacteria.

SPRUE. A disorder of impaired absorption of nutrients from the diet by the small intestine (malabsorption), resulting in malnutrition. Two forms of sprue exist: tropical sprue, which occurs mainly in tropical regions; and celiac sprue, which occurs more widely and is due to sensitivity to the wheat protein gluten.

SPUR. Any projection from a bone.

SPUTUM. The mixture of mucus, irritants, and other substances expelled from the lungs by coughing.

SPUTUM CULTURE. A laboratory analysis of the fluid produced from the lungs during coughing. A sputum culture can confirm the presence of pathogens in the respiratory system, and help to diagnose certain respiratory infections, including bronchitis, tuberculosis, and pneumonia.

SPUTUM CYTOLOGY. A lab test in which a microscope is used to check for cancer cells in the sputum.

SQUAMOUS CELL CARCINOMA. A form of skin cancer that usually originates in sun-damaged areas or pre-existing lesions; at first local and superficial, it may later spread to other areas of the body.

SQUAMOUS CELLS. Thin, flat cells of the surfaces of the skin and cervix and linings of various organs.

SQUAMOUS EPITHELIAL CELLS. Thin, flat cells found in layers or sheets covering surfaces such as skin and the linings of blood vessels and esophagus.

SQUAMOUS INTRAEPITHELIAL LESION (SIL). A term used to categorize the severity of abnormal changes arising in the squamous, or outermost, layer of the cervix.

STAGING. The classification of cancerous tumors according to the extent and spread of the tumor.

STAMINA. Staying power, endurance.

STANDARD DEVIATION. A measure of the distribution of scores around the average (mean). In a normal distribution, two standard deviations above and below the mean includes about 95% of all samples.

STANDARDIZATION. The process of determining established norms and procedures for a test to act as a standard reference point for future test results.

STAPHYLOCOCCAL INFECTION. An infection caused by any of several pathogenic species of *Staphylococcus*, commonly characterized by the formation of abscesses of the skin or other organs.

STAPHYLOCOCCAL SCALDED SKIN SYNDROME. A disease caused by *Staphylococcus aureus,* in which large sheets of skin may peel away from the body. It most often affects infants, young children, and people with weakened immune systems.

STAPHYLOCOCCUS. A genus of bacteria that is commonly found on human skin and mucous membranes.

STATIC ENCEPHALOPATHY. A disease of the brain that does not get better or worse.

STATINS. A group of medications given to lower blood cholesterol levels that work by inhibiting an enzyme involved in cholesterol formation. Statins are also known as HMG-CoA reductase inhibitors.

STATUS MIGRAINOSUS. The medical term for an acute migraine headache that lasts 72 hours or longer.

STEAM DISTILLATION. A process of extracting essential oils from plant products through a heating and evaporation process.

STEATORRHEA. An excessive amount of fat in the stool.

STEM CELL. Undifferentiated cell that retains the ability to develop into any one of numerous cell types.

STENOSIS (PLURAL, STENOSES). The narrowing or constriction of an opening or passageway in the body.

STENT. A device made of expandable, metal mesh that is placed (by using a balloon catheter) at the site of a narrowing artery; the stent stays in place to keep the artery open.

STEREOPSIS. The visual perception of depth, or the ability to see three-dimensionally. For this to occur, the person must be binocular.

STEREOTACTIC. Characterized by precise positioning in space. When applied to radiosurgery, stereotactic refers to a system of three-dimensional coordinates for locating the target site.

STEREOTACTIC BIOPSY. A biopsy taken by precisely locating areas of abnormal growth through the use of delicate instruments.

STEREOTACTIC BRAIN NEEDLE BIOPSY. In this procedure a computer uses information from a CT or MRI to create a three-dimensional map of the operation site to better guide the needle to perform the biopsy.

STEREOTACTIC TECHNIQUE. A technique used by neurosurgeons to pinpoint locations within the brain. It employs computer imaging to create an external frame of reference.

STERILE. Free of microorganisms.

STERILITY. Inability to conceive a child.

STERNUM. The breastbone. The sternum is located over the heart, is the point of attachment for ribs at the front of the body, and provides protection to the heart beneath it.

STEROIDS. A class of hormones and drugs that includes sex and stress hormones and anti-inflammatory medications, contraceptives, and growth-promoting substances.

STEROLS. Steroid alcohols, such as cholesterol, that are widely distributed in the body.

STETHOSCOPE. A medical instrument for listening to a patient's heart and lungs.

STEVENS-JOHNSON SYNDROME. A severe inflammatory skin eruption that occurs as a result of an allergic reaction or respiratory infection.

STIMULANTS. A class of psychoactive drugs that improve alertness and concentration. They may be used to treat attention disorders but have a high potential for abuse.

STIMULUS. A factor capable of eliciting a response in a nerve.

STOCKINETTE. A soft elastic material used for bandages and clothing for infants.

STOMA. A surgical opening made in the abdominal wall to allow waste products to pass directly to the outside.

STOMATITIS. Inflammation of the lining of the mouth, gums, or tongue.

STONES. Also known as calculi, stones result from an excessive build-up of mineral crystals in the kidney. Symptoms of stones include intense pain in the lower back or abdomen, urinary tract infection, fever, burning sensation on urination, and/or blood in the urine.

STOOL. The solid waste that is left after food is digested. Stool forms in the intestines and passes out of the body through the anus.

STRABISMUS. A disorder where the two eyes do not point in the same direction.

STRANGULATED HERNIA. A hernia that is so tightly incarcerated outside the abdominal wall that the intestine is blocked and the blood supply to that part of the intestine is cut off.

STRANGULATED OBSTRUCTION. An obstruction in which a loop of the intestine has its blood supply cut off.

STRANGULATION. A condition in which a vessel, section of the intestine, or other body part is compressed or constricted to the point that blood cannot circulate.

STRAWBERRY TONGUE. A sign of scarlet fever in which the tongue appears to have a red coating with large raised bumps.

STREET DRUG. A substance purchased from a drug dealer; may be a legal substance, sold without a prescription and not for medical use, or it may be a substance that is illegal to possess.

STREP THROAT. An infection of the throat caused by bacteria of the *Streptococcus* family, which causes tonsillitis.

STREPTOCOCCAL INFECTION. An infection caused by a pathogenic bacteria of one of several species of the genus *Streptococcus* or their toxins. Almost any organ in the body may be involved.

STREPTOCOCCUS (PLURAL, STREPTOCOCCI). A genus of spherical-shaped anaerobic bacteria occurring in pairs or chains.

STRESS FRACTURE. A crack in a bone (usually the result of overuse).

STRESS INCONTINENCE. Leakage of urine upon movements that put pressure on the abdominal muscles such as coughing, sneezing, laughing, or exercise. One of four types of incontinence.

STRESS MANAGEMENT. A set of techniques and programs intended to help people deal more effectively with stress in their lives by analyzing the specific stressors and taking positive actions to minimize their effects.

STRESS TEST. A test that involves an electrocardiogram during rest and exercise to determine how the heart responds to stress.

STRESSOR. A stimulus or event that provokes a stress response in an organism. Stressors can be categorized as acute or chronic, and as external or internal to the organism.

STRIATED MUSCLE. Also known as striped muscle; it includes muscles of the skeletal system and of the heart.

STRICTURE. An abnormal narrowing of a tube or passageway.

STRIDOR. A harsh or crowing breath sound caused by partial blockage of the patient's upper airway.

STRING TEST. A test performed to diagnose threadworm infection. The patient is asked to swallow a weighted string that absorbs stomach juices, which can be analyzed for the presence of threadworm larvae.

STROKE. Irreversible damage to the brain caused by insufficient blood flow to the brain as the result of a blocked artery. Damage can include loss of speech or vision, paralysis, cognitive impairment, and death.

STROMA. A term used to describe the supportive tissue surrounding a particular structure, such as an organ.

STRUCTURAL INTEGRATION. The term used to describe the method and philosophy of life associated with Rolfing. Its fundamental concept is the vertical line.

STUNTING. A height more than two standard deviations from the median height for the age in the reference population.

STYPTIC. Any remedy with an astringent and hemostatic (stopping bleeding) quality.

SUBACUTE. An abnormal condition present in a person who appears to be clinically well.

SUBARACHNOID. Referring to the space underneath the arachnoid mater.

SUBARACHNOID HEMORRHAGE. A cause of some strokes in which arteries on the surface of the brain begin bleeding.

SUBARACHNOID SPACE. A space between membranes that covers and protects the brain.

SUBCLAVIAN. Located beneath the collarbone (clavicle).

SUBCORTICAL APHASIA. A condition characterized by either partial or total loss of the ability to communicate verbally or using written words as a result of damage to non language-dominated areas of the brain. This condition may be caused by a stroke, head injury, brain tumor, or infection.

SUBCUTANEOUS. Referring to the area beneath the skin.

SUBCUTANEOUS EMPHYSEMA. A pathologic accumulation of air underneath the skin resulting from improper insufflation technique.

SUBDURAL HEMATOMA. A collection of blood or a clot trapped under the dura mater, the outermost membrane surrounding the brain and spinal cord, often causing neurological damage due to pressure on the brain.

SUBLUXATION. Misalignment between vertebrae that structurally and functionally impairs nerve function.

SUBSTANTIA NIGRA. One of the movement control centers of the brain.

SUBTHRESHOLD. A term used in psychiatry to describe a condition that has significant clinical features but does not meet the full criteria of major disorders. Adjustment disorders are considered subthreshold disorders.

SUCCIMER (CHEMET). A drug used to remove excess lead from the body.

SUCCUSSION. The act of shaking diluted homeopathic remedies as part of the process of potentization.

SUCROSE. The scientific name for table sugar. Sucrose is a disaccharide derived from glucose and fructose.

SUGARS. Those carbohydrates having the general composition of one part carbon, two parts hydrogen, and one part oxygen.

SUICIDE GESTURE. Attempted suicide characterized by a low-lethality method, low level of intent or planning, and little physical damage; sometimes called pseudocide.

SUICIDE MAGNET. A bridge, tall building, or geographic location that acquires a reputation for attracting people who want to commit suicide and attempt it.

SULFADOXONE/PYRIMETHAMINE (FANSIDAR). An antimalarial drug developed in the 1960s. It is the first drug tried in some parts of the world where chloroquine resistance is widespread. It has been associated with severe allergic reactions due to its sulfa component.

SULFINPYRAZONE. A drug that corrects hyperuricemia by increasing the urinary excretion of urate.

SULFITE. A type of preservative that causes allergic reactions in some people.

SULFONAMIDE DRUGS. A group of antibacterial drugs used to treat infections of the lungs and skin, among other things.

SUNBLOCK. A skin preparation containing an active ingredient, such as titanium oxide, that prevents sunburn by physically blocking out ultraviolet radiation.

SUNSCREEN. Products that block the damaging rays of the sun. Good sunscreens contain either para-aminobenzoic acid (PABA) or benzophenone, or both. Sunscreen protection factors range from 2–45.

SUNSETTING. Confusion or agitation in the evening.

SUPERINFECTION. Infection by a second virus after a previous infection by a different virus has become well established.

SUPERIOR MESENTERIC ARTERY SYNDROME. A condition in which a person vomits after meals due to blockage of the blood supply to the intestine.

SUPERIOR VENA CAVA. The major vein that carries blood from the upper body to the heart.

SUPERIOR VENA CAVA (SVC) SYNDROME. A condition seen in lung cancer patients where the tumor presses against a large blood vessel and causes various symptoms.

SUPPORT GROUP. A group whose primary purpose is the provision of empathy and emotional support for its members. Support groups are less formal and less goal-directed than group therapy.

SUPPORTIVE THERAPY. An approach to psychotherapy that seeks to encourage the patient or offer emotional support to him or her, as distinct from insight-oriented or educational approaches to treatment.

SUPPOSITORY. A solid medication that slowly dissolves after being inserted into the rectum or other body cavity.

SUPPURATE. To produce or discharge pus.

SUPRAGLOTTITIS. Another term for epiglottitis.

SUPRASPINATUS. A muscle at the top of the shoulder blade.

SUPRAVENTRICULAR. A term for an event that occurs in the upper chambers (atria) of the heart.

SUPRAVENTRICULAR TACHYCARDIA. A fast heart beat that originates above the ventricles.

SURFACE TENSION. The attraction of molecules in a fluid for each other.

SURFACTANT. A substance secreted by the alveoli in the lungs that reduces the surface tension of lung fluids, allowing gas exchange and helping maintain the elasticity of lung tissue.

SWEAT GLANDS. Tiny glands scattered throughout the skin that produce sweat.

SWIMMER'S ITCH. An allergic skin inflammation caused by a sensitivity to flatworms that die under the skin, causing an itchy rash.

SYDENHAM'S CHOREA. A childhood disorder of the central nervous system. Once called St. Vitus' dance, the condition is characterized by involuntary, jerky movements that usually follow an attack of rheumatic fever. Rare in the United States today, but a common disorder in developing countries. Usually resolves in two to three months with no long-term adverse effects.

SYLVATIC. Pertaining to or living in the woods or forested areas. The form of yellow fever transmitted by mosquitoes to rainforest monkeys is called sylvatic yellow fever.

SYMPATHETIC NERVE. A nerve of the autonomic nervous system that regulates involuntary and automatic reactions, especially to stress.

SYMPATHETIC NERVOUS SYSTEM. A division of the autonomic nervous sytem, the portion of the nervous system that controls involuntary bodily functions such as heart rate.

SYMPATHOMIMETIC. Denoting a drug that mimics the effects of stimulation of organs and structures by the sympathetic nervous system. The sympathetic nervous system pertains to the part of the nervous system originating in the thoracic and lumbar regions of the spinal cord.

SYMPTOMATIC. Refers to treatment that addresses the symptoms of an illness, but not its underlying cause.

SYNAPSE. A connection between nerve cells, by which nervous excitation is transferred from one cell to the other.

SYNCOPE. A loss of consciousness over a short period of time, caused by a temporary lack of oxygen in the brain.

SYNDACTYLY. A fusion of two or more toes or fingers.

SYNDROME. A collection of abnormalities that occur often enough to suggest they have a common cause.

SYNDROME OF INAPPROPRIATE SECRETION OF ANTIDIURETIC HORMONE (SIADH). A potentially fatal condition of excessive secretion of ADH, leading to concentrated urine and blood sodium deficiency.

SYNDROME X. A term that was sometimes used for metabolic syndrome when the syndrome was first identified in the 1960s.

SYNERGISTIC. The combined action of two or more processes is greater than the sum of each acting separately.

SYNGENEIC. Referring to a bone marrow transplant from one identical twin to the other.

SYNOVIAL FLUID (SF). A fluid secreted by tissues surrounding the joints that lubricates the joints.

SYNOVIAL JOINT. A joint that allows for bone movement.

SYNOVIAL MEMBRANE. A layer of connective tissue that lines the cavities of joints.

SYNOVIAL TENDON SHEATH. Where the tendons cross joints, they are sheathed in thin membranes known as synovium, which provide lubrication to decrease friction.

SYNOVITIS. Inflammation of the synovium, a membrane found inside joints.

SYNOVIUM. A fibrous envelope that produces a fluid to help to reduce friction and wear in a joint.

SYPHILIS. A sexually transmitted disease caused by a bacteria. There is also a second form that is not sexually transmitted but passed on by direct contact with the patient or through use of shared food dishes and utensils.

SYSTEMIC. A term used to describe a medicine that has effects throughout the body as opposed to topical drugs that work on the skin. Most medicines that are taken by mouth or by injection are systemic drugs.

SYSTEMIC CIRCULATION. Through the body, as opposed to pulmonary circulation (through the lungs).

SYSTEMIC DISEASE. A disease that affects the entire body instead of a specific organ.

SYSTEMIC LUPUS ERYTHEMATOSUS (SLE). A chronic, inflammatory, autoimmune disorder in which the individual's immune system attacks, injures, and destroys the body's own organs and tissues. It may affect many organ systems including the skin, joints, lungs, heart, and kidneys.

SYSTEMIC SCLEROSIS. A rare disorder that causes thickening and scarring of multiple organ systems.

SYSTOLE. The phase of blood circulation in which the heart's pumping chambers (ventricles) are actively pumping blood. The ventricles are squeezing (contracting) forcefully, and the pressure against the walls of the arteries is at its highest.

SYSTOLIC. Relating to or occuring during systole (e.g., systolic blood pressure).

T

T CELLS (T LYMPHOCYTES). White blood cells that originate in the thymus gland. T cells regulate the immune system's response to infections, including HIV. CD4 lymphocytes are a subset of T lymphocytes.

TABES DORSALIS. A progressive deterioration of the spinal cord and spinal nerves that is associated with tertiary syphilis.

TABLEWORK. The passive phase of Trager therapy, in which the practitioner uses gentle and noninvasive movements to allow the client to relax deeply and experience physical movement as free and effortless.

TAC. A topical anesthetic mixture containing tetracaine, epinephrine (adrenaline), and cocaine.

TACHYCARDIA. Rapid heart rate, defined as more than 100 beats per minute.

TAENIASIS. Parasitic infection caused by the presence of tapeworms from the *Taenia* genus, such as the pork tapeworm (*Taenia solium*) or the beef tapeworm (*Taenia saginata*).

TALK THERAPY. A general term for any form of psychotherapy based on conversational interaction between a trained therapist and a client. It includes psychodynamic therapy, humanistic therapy, and the various behavioral therapies as well as psychoanalysis.

TAMPONADE. To occlude by pressure.

TANNER STAGES. A set of scales to measure sexual development during puberty, named for James Tanner (1920–2010), the British pediatrician who devised it.

TAPERING. Gradually reducing the intake of an addictive substance (such as nicotine) as part of a cessation effort.

TAPEWORM. An intestinal parasite that attaches to the intestine or travels to other organs such as the liver and lungs.

TARDIVE DYSKINESIA. Involuntary movements of the face and/or body which are a side effect of the long-term use of some older antipsychotic (neuroleptic) drugs. Tardive dyskinesia affects 15-20% of patients on long-term neuroleptic treatment.

TARGET HEART RATE. The heart rate, in beats per minute (bpm), that should be maintained during cardiovascular exercise by an individual of a given age.

TARTAR. A hardened yellow or brown mineral deposit from unremoved plaque; also called calculus.

TASER. Also called a conducted electrical weapon or CEW, a taser is an electroshock device used by some police departments in various countries to subdue armed or otherwise dangerous suspects without having to use lethal force. Tasers work by interfering with the brain's capacity to control voluntary muscles. The name *taser* is an acronym for *Thomas A. Swift's Electric Rifle*, an adventure novel about a fictional weapon published in 1911.

TAU PROTEIN. A protein involved in maintaining the internal structure of nerve cells. Tau protein is damaged in AD and forms neurofibrillary tangles.

TAURINE. An amino acid that is important in the development of brain tissue. Taurine is a key component of bile which is needed to digest fats.

TAY-SACHS DISEASE. An inherited disease prevalent among the Ashkenazi Jewish population of the United States. Infants with the disease are unable to process a certain type of fat that accumulates in nerve and brain cells, causing mental and physical retardation, and death by age four.

TD. Tetanus and diphtheria vaccine.

TEAR. A drop of the clear, salty fluid secreted by the lachrimal gland.

TECHNETIUM. A radioactive isotope frequently used in radionuclide scanning of the heart and other organs. It is produced during nuclear fission reactions.

TELANGIECTASIAS. Very small arteriovenous malformations, or connections between the arteries and veins. The result is small red spots on the skin known as "spider veins."

TELEMEDICINE. The use of communications or information technology to deliver clinical care or diagnosis. The medical information may be conveyed by telephone, Internet connections, or other electronic networks.

TEMPEH. A fermented cake of soybeans and other grains; it is a staple food in Indonesia.

TEMPERAMENT. A person's natural or genetically determined disposition.

TEMPORAL ARTERITIS. Also known as giant cell arteritis. Inflammation of the large arteries located in the temples which is marked by the presence of giant cells and symptoms of headache and facial pain.

TEMPORAL BONES. The compound bones that form the left and right sides of the skull.

TEMPORAL LOBE. The part of each side or hemisphere of the brain that is on the side of the head, nearest the ears.

TEMPOROMANDIBULAR JOINT (TMJ). One of a pair of joints that attaches the mandible of the jaw to the temporal bone of the skull. It is a combination of a hinge and a gliding joint.

TEMPOROMANDIBULAR JOINT SYNDROME (TMJ SYNDROME). An incorrect alignment of the lower jaw to the skull that causes the bite to be off line. It causes pain, chronic headaches, nausea, and other symptoms.

TENDINITIS. Inflammation of a tendon, which is a tough band of tissue that connects muscle to bone.

TENDON. A strong connective tissue that connects muscle to bone.

TENDON REFLEX. A reflex action, such as a knee jerk, in which a light blow to the tendon causes the muscle to contract.

TENDON SHEATH. A membrane covering a tendon.

TENESMUS. Straining to urinate or defecate without being able to do so. Tenesmus is a characteristic feature of bacillary dysentery.

TENOSYNOVITIS. Inflammation of a tendon and its enveloping sheath, usually resulting from overuse injury.

TENOTOMY. A surgical procedure that cuts the tendon of a contracted muscle to allow lengthening.

TENS. The abbreviation for transcutaneous electrical nerve stimulation, a technique used to control chronic pain. Electrodes placed over the painful area deliver a mild electrical impulse to nearby nerve pathways.

TENSILON TEST. A test for diagnosing myasthenia gravis. Tensilon is injected into a vein and, if the person has MG, their muscle strength will improve for about five minutes.

TENSION-TYPE HEADACHE. A dull pain that seems to exert pressure on the head; the most common form of headache.

TERATOGEN. Any drug, chemical, maternal disease, or exposure that can cause physical or functional defects in an exposed embryo or fetus.

TESTES. The pair of male reproductive glands enclosed in the scrotum that produce the male sex hormone testosterone and the spermatozoa. The singular form is testis.

TESTICULAR CANCER. A cancer that originates in the testes.

TESTOSTERONE. Male hormone produced by the testes and (in small amounts) in the ovaries. Testosterone is responsible for some masculine secondary sex characteristics such as growth of body hair and deepening voice.

TETANUS. An acute infectious disease caused by a toxin produced by the bacterium *Clostridium tetani* and usually introduced into the body through a wound.

TETANUS TOXOID. Tetanus toxoid is a vaccine used to prevent tetanus (also known as lockjaw).

TETANY. A disorder of the nervous system characterized by muscle cramps, spasms of the arms and legs, and numbness of the extremities.

TETRALOGY OF FALLOT. A cyanotic defect in which the blood pumped through the body has too little oxygen. Tetralogy of Fallot includes four defects: a large hole between the ventricles, narrowing at or beneath the pulmonary valve, an overly muscular right ventricle, and an aorta over the large hole.

THALAMOTOMY. A surgical procedure that destroys part of a large oval area of gray matter within the brain that acts as a relay center for nerve impulses. The thalamus is an essential part of the nerve pathway that controls intentional movement. By destroying tissue at a particular spot on the thalamus, the surgeon can interrupt the nerve signals that cause tremor.

THALAMUS. A large oval area of gray matter within the brain that relays nerve impulses from the basal ganglia to the cerebellum, both parts of the brain that control and regulate muscle movement.

THALASSEMIA. A group of inherited disorders that affects hemoglobin production. Because hemoglobin production is impaired, a person with this disorder may suffer mild to severe anemia. Certain types of thalassemia can be fatal.

THANATOLOGY. The medical, psychological, or legal study of death and dying.

THELARCHE. The onset of breast development in girls. It is usually first noticed as a firm but tender lump directly under the center of the nipple.

THERAPEUTIC. Curative or healing.

THIAMINE. A B vitamin essential for the body to process carbohydrates and fats.

THIAMINE PYROPHOSPHATE (TPP). The coenzyme containing thiamine that is essential in converting glucose to energy.

THIAZIDE DIURETIC. A particular class of medication that encourages urine production.

THIAZIDES. A group of drugs used to increase urine output.

THIMEROSAL. A crystalline organic mercury compound used as an antifungal and antibacterial agent and present in very small amounts in some vaccines.

THORACENTESIS. A procedure in which fluid is withdrawn from the pleural cavity through a needle inserted between the ribs. The fluid may be withdrawn either for diagnostic tests or to drain the cavity.

THORACIC. Pertaining to the area bounded by the rib cage.

THORACIC AORTIC ANEURYSM. Occurs when an area in the thoracic section of the aorta (the chest) is weakened and bulges like a balloon. The thoracic section supplies blood to the upper body.

THORACIC VERTEBRAE. The vertebrae in the chest region to which the ribs attach.

THORACOSCOPY. Examination of the contents of the chest through a thin, lighted tube passed through a small incision.

THORACOTOMY. Open chest surgery.

THORAX. The chest area, which runs between the abdomen and neck and is encased in the ribs.

THREADWORM. Any long, thin nematode worm.

THROAT CULTURE. A test for strep throat that involves swabbing the back of the throat and sending the swab to a laboratory, which will determine whether bacteria is present.

THROMBIN. An enzyme in blood plasma that helps to convert fibrinogen to fibrin during the last stage of the clotting process.

THROMBIN INHIBITOR. Thrombin inhibitors are one type of anticoagulant medication, used to help prevent formation of harmful blood clots in the body by blocking the activity of thrombin.

THROMBOCYTE. Another name for platelet.

THROMBOCYTOPENIA. An abnormal decline in the number of platelets in the blood.

THROMBOCYTOSIS. A vascular condition characterized by high blood platelet counts.

THROMBOEMBOLISM. A clot in the blood that forms and blocks a blood vessel. It can lead to infarction, or death of the surrounding tissue due to lack of blood supply.

THROMBOLYSIS. A treatment that opens up blood flow and may prevent permanent damage to the blood vessels.

THROMBOLYTICS. Drugs that dissolve blood clots. Thrombolytics are used to treat embolisms.

THROMBOPHLEBITIS. Inflammation of a vein, associated with the formation of a blood clot.

THROMBOPLASTIN. A protein in blood that converts prothrombin to thrombin.

THROMBOSIS. Formation of a clot in the blood that either blocks, or partially blocks a blood vessel. The thrombus may lead to infarction, or death of tissue, due to a blocked blood supply.

THROMBOTIC. Relating to, caused by, or characterized by thrombosis.

THROMBUS. A blood clot that may form in a blood vessel or in one of the cavities of the heart.

THRUSH. A disease of the mouth, caused by *Candida albicans* and characterized by a whitish growth and ulcers. It can be diagnosed with the KOH test.

THYMOMA. A tumor that originates in the thymus, a small gland just in front of the heart that produces hormones necessary for the development of certain components of the immune system.

THYMUS. A gland located behind the sternum that coordinates the development of the immune system.

THYROID. A butterfly-shaped gland in front and to the sides of the upper part of the windpipe; influences body processes like growth, development, reproduction, and metabolism.

THYROID STORM. A rare but potentially life-threatening complication of hyperthyroidism, characterized by fever over 104°F, irregular heart rhythm, vomiting, diarrhea, dehydration, coma, and death.

THYROIDECTOMY. Surgical removal of the thyroid gland.

THYROIDITIS. Inflammation of the thyroid gland. It can be caused by a viral infection, a malfunction of the immune system, or certain medications.

THYROID-STIMULATING HORMONE (TSH). A hormone produced by the pituitary gland that stimulates the thyroid gland to produce the hormones that regulate metabolism. Also called thyrotropin.

THYROTOXICOSIS. An excess of thyroid hormones in the blood, causing a variety of symptoms that include rapid heart beat, sweating, anxiety, and tremor.

THYROXINE (T_4). The thyroid hormone that regulates many essential body processes.

TIBIA. One of the two bones of the lower leg.

TIC. Brief and intermittent involuntary movement or sound.

TICK-BORNE DISEASE. A disease that is spread to animals by the bite of an infected tick.

TILT TABLE; TILTBOARD. An apparatus for rotating a person from horizontal to an oblique or vertical position.

TINEA. A superficial infection of the skin, hair, or nails, caused by a fungus and commonly known as ringworm.

TINNITUS. A sensation of noise or ringing in the ears. Tinnitus may be a symptom of cerumen impaction.

TISSUE FACTOR. A glycoprotein involved in blood coagulation.

TISSUE PLASMINOGEN ACTIVATOR (TPA). A substance that is sometimes given to patients within three hours of a stroke to dissolve blood clots within the brain.

TITER. The concentration of a substance in a given sample of blood or other tissue fluid.

TITRATE. To analyze the best end point (for dose) for a medication.

TNM SYSTEM. A commonly used staging system that examines the main tumor (T), the lymph nodes (N), and metastases (M).

TOCOLYTIC. A medication that inhibits uterine contractions.

TOFU. A soft cheeselike food made from curdled soybean milk.

TOLERANCE. The requirement for higher doses of a substance or more frequent engagement in an activity to achieve the same effect.

TOMOGRAPHY. A technique of using ultrasound, gamma rays, or x rays to produce a focused image of the structures across a specific depth within the body, while blurring details at other depths.

TONIFICATION. Acupuncture technique for strengthening the body.

TONOMETER. An instrument that measures intraocular pressure (IOP).

TONOMETRY. The measurement of pressure.

TONSILLECTOMY. Surgical removal of the tonsils.

TONSILLITIS. Inflammation of the tonsils, which are in the back of the throat.

TONSILS. Oval masses of lymphoid tissue on each side of the throat.

TOPHUS (PLURAL, TOPHI). A chalky deposit of a uric acid compound found in gout. Tophi occur most frequently around joints and in the external ear.

TOPICAL. Referring to a medication or other preparation applied to the skin or the outside of the body.

TOPICAL CORTICOSTEROIDS. Cortisone and related drugs used on the skin and in the eye, usually for allergic conditions.

TORSION. The action of twisting.

TORTUOUS ARTERIES. Arteries with many bends and twists.

TOTAL GASTRECTOMY. Surgical removal (excision) of the entire stomach.

TOTAL LUNG CAPACITY. The volume of air in the lungs at the end of a deep breath. The normal value in adults is between 4 and 6 quarts.

TOTAL PARENTERAL NUTRITION (TPN). Intravenous administration of a solution containing all of the nutrients required by the body, such as protein, fat, calories, vitamins, and minerals. TPN provides a complete and balanced source of nutrients for patients who cannot consume a normal diet.

TOTAL-SKIN ELECTRON BEAM THERAPY. A method of radiation therapy used to treat CTCL that involves bombarding the entire body surface with high-energy electrons.

TOURETTE SYNDROME. An abnormal condition that causes uncontrollable facial grimaces and tics as well as arm and shoulder movements. Tourette syndrome is perhaps best known for uncontrollable vocal tics that include grunts, shouts, and use of obscene language (coprolalia).

TOURNIQUET. Any device that is used to compress a blood vessel to stop bleeding or to collect a blood sample. Phlebotomists usually use an elastic band as a tourniquet.

TOXEMIA. Poisoning of the blood.

TOXIC. Poisonous.

TOXIC MEGACOLON. Acute enlargement or dilation of the large intestine.

TOXIC OXYGEN. Oxygen is required for life, as it is needed for energy production. When oxygen is used by the body, most of it is converted to water. However, a small fraction of the oxygen breathed is converted to toxic oxygen. The body uses several different processes for preventing and repairing toxic-oxygen damage. One of these processes involves vitamin E.

TOXIC SHOCK SYNDROME. An uncommon, but potentially fatal, disease that has been associated with the use of diaphragms and vaginal tampons. The symptoms include high fever, vomiting, and diarrhea.

TOXIC THYROID ADENOMA. Self-contained concentrations of thyroid tissue that may produce excessive amounts of thyroid hormone.

TOXICOLOGY. The branch of medicine that deals with the effects, detection, and treatment of poisons.

TOXIN. A substance that has poisonous effects on the body.

TOXOID. A preparation made from inactivated exotoxin, used in immunization.

TRABECULAR MESHWORK. A sponge-like tissue located near the cornea and iris that functions to drain the aqueous humor from the eye into the blood.

TRABECULOPLASTY. Laser surgery that creates perforations in the trabeculum, to drain built up aqueous humor and relieve pressure.

TRABECULUM. Tissue that is a drainage point for aqueous humor in the eye.

TRACE ELEMENTS. A group of elements that are present in the human body in very small amounts but are nonetheless important to good health. They include chromium, copper, cobalt, iodine, iron, selenium, and zinc. Trace elements are also called micronutrients.

TRACER. A substance containing a radioisotope, injected into the body and followed in order to obtain information about various metabolic processes in the body.

TRACHEA. The tube that leads from the larynx or voice box to two major air passages that bring oxygen to each lung. The trachea is sometimes called the windpipe.

TRACHEOBRONCHIAL. Pertaining both to the tracheal and bronchial tubes or to their junction.

TRACHEOSTOMY. A procedure in which a small opening is made in the neck and into the trachea. A breathing tube is then placed through this opening.

TRACHEOSTOMY TUBE. A tube that is inserted into an incision in the trachea (tracheostomy) to relieve upper airway obstruction.

TRACHEOTOMY. The surgical creation of an opening in the trachea that functions as an alternative airway so that the patient may breathe.

TRACTION. The process of placing a bone, limb, or group of muscles under tension by applying weights and pulleys. The goal is to realign or immobilize the part or to relieve pressure on that particular area to promote healing and restore function.

TRANQUILIZER (MINOR). A drug that has a calming effect and is used to treat anxiety and emotional tension.

TRANS FAT. Fat that is produced by hydrogenation during food processing; trans fats increase bad cholesterol and decrease good cholesterol.

TRANSABDOMINAL ULTRASOUND. A small handheld instrument called a transducer is passed back and forth over the pelvic area to provide images of the abdomen.

TRANSCENDENTAL MEDITATION (TM). A meditation technique based on Hindu practices that involves the repetition of a mantra.

TRANSCORTICAL APHASIA. A condition characterized by either partial or total loss of the ability to communicate verbally or using written words that does not affect an individual's ability to repeat words, phrases, and sentences.

TRANSCRANIAL MAGNETIC STIMULATION. A procedure used to treat patients with depression.

TRANSCUTANEOUS ELECTRICAL NERVE STIMULATION (TENS). A treatment in which a mild electrical current is passed through electrodes on the skin to stimulate nerves and block pain signals.

TRANSDUCER. A device that converts electrical signals into ultrasound waves and ultrasound waves back into electrical impulses.

TRANSESOPHAGEAL ECHOCARDIOGRAPHY. A diagnostic test using an ultrasound device, passed into the esophagus of the patient, to create a clear image of the heart muscle.

TRANSFERENCE. The redirection of feelings and thoughts from early childhood experiences toward a person in the present, usually the analyst.

TRANSFERRIN. A protein in blood plasma that carries iron derived from food intake to the liver, spleen, and bone marrow.

TRANSFUSION. The therapeutic introduction of blood or a blood component into a patient's bloodstream.

TRANSGENIC ANIMAL. Animals that have had genes from other species inserted into their genetic code.

TRANSIENT ISCHEMIC ATTACK (TIA). A brief stroke lasting from a few minutes to 24 hours. TIAs are sometimes called mini-strokes.

TRANSILLUMINATION. A technique by which a strong light is shone through body tissues to examine an organ or structure.

TRANSLOCATION. The transfer of one part of a chromosome to another chromosome during cell division.

TRANSPLANTATION. The removal of tissue from one part of the body for implantation to another part of the body; or the removal of tissue or an organ from one individual and its implantation in another individual by surgery.

TRANSPOSITION OF THE GREAT ARTERIES. A cyanotic defect in which the blood pumped through the body has too little oxygen. The pulmonary artery and the aorta are reversed.

TRANSSEXUAL. A person with gender identity disorder who has an overwhelming desire to change anatomic sex; one who seeks hormonal or surgical treatment to change sex.

TRANSTRACHEAL BIOPSY. A transtracheal biopsy is the removal of a small piece of tissue from across the trachea or windpipe for examination under a microscope.

TRANSUDATE. The type of pleural effusion seen with heart failure or other disorders of the circulation. It features clear fluid containing few cells and little protein.

TRANSUDATION. The passage of fluid, as through blood vessels into the vagina.

TRANSURETHRAL RESECTION OF THE PROSTATE (TURP). Surgical removal of a portion of the prostate through the urethra, a method of treating the symptoms of an enlarged prostate, whether from BPH or cancer.

TRANSVERSE PRESENTATION. A position in which the fetus lies sideways against the birth canal, with a shoulder or arm possibly entering the canal.

TRANSVESTITISM. Sexual arousal from dressing in the clothes of the opposite sex.

TRAUMA. A disastrous or life-threatening event that can cause severe emotional distress, including dissociative symptoms and disorders.

TRAUMATIC GRIEF. Grief resulting from the loss of a loved one in a traumatic situation (natural or transportation disaster, act of terrorism or mass murder, etc.).

TRAUMATIC SHOCK. A condition of depressed body functions as a reaction to injury with loss of body fluids or lack of oxygen. Signs of traumatic shock include weak and rapid pulse, shallow and rapid breathing, and pale, cool, clammy skin.

TRAVELER'S DIARRHEA. An illness due to infection from a bacteria or parasite that occurs in persons traveling to areas where there is a high frequency of the illness. The disease is usually spread by contaminated food or water.

TREMATODE. Parasitic flatworms or another name for fluke, taken from a Greek word that means having holes.

TREMOR. Shakiness or trembling.

TREMOR CONTROL THERAPY. A method for controlling tremor by self-administered shocks to the part of the brain that controls intentional movement (thalamus). An electrode attached to an insulated lead wire is implanted in the brain; the battery power source is implanted under the skin of the chest, and an extension wire is tunneled under the skin to connect the battery to the lead. The patient turns on the power source to deliver the electrical impulse and interrupt the tremor.

TREPHINE. A small surgical instrument that is rotated to cut a circular incision.

TREPONEMA PALLIDUM. The spirochete bacterium that causes syphilis.

TRETINOIN. A naturally occurring retinoid, derived from vitamin A, that treats acne by increasing the turnover (death and replacement) of skin cells.

TRIANGLING. A process in which two family members lower the tension level between them by drawing in a third member.

TRICHIASIS. A disease of the eye, in which the eyelashes, being turned in upon the eyeball, produce constant irritation by the motion of the lids.

TRICHINA. An individual example of *Trichinella spiralis*.

TRICHINOSIS. A roundworm infection, usually contracted by eating raw or undercooked meat. Trichinosis is rare in the United States but a common infection in some parts of the world.

TRICHOTILLOMANIA. An impulse or compulsion to pull out one's own hair.

TRICUSPID VALVE. A fold in between the right atrium and the right ventricle of the heart that directs blood that needs oxygen to the lungs.

TRIDOSHA. The combination of three basic principles of energy, or biological humor, that comprise life, according to Ayurvedic philosophy.

TRIGEMINAL NEURALGIA. Brief episodes of severe shooting pain on one side of the face caused by inflammation of the root of the trigeminal nerve. Also referred to as tic douloureux.

TRIGLYCERIDE. A substance formed in the body from fat in the diet. Triglycerides are the main fatty materials in the blood. Together with protein, they make up high- and low-density lipoproteins (HDLs and LDLs). Triglyceride levels are important in the diagnosis and treatment of many diseases including high blood pressure, diabetes, and heart disease.

TRIIODOTHYRONINE (T_3). A thyroid hormone similar to thyroxine but more powerful. Preparations of triiodothyronine are used in treating hypothyroidism.

TRIMESTER. The first third or 13 weeks of pregnancy.

TRIMETHOPRIM-SULFAMETHOXAZOLE (TMP-SMX). An antibiotic used to treat and prevent PCP.

TRINUCLEOTIDE REPEAT EXPANSION. A sequence of three nucleotides that is repeated too many times in a section of a gene.

TRIPLOIDY. The condition where an individual has three entire sets of chromosomes instead of the usual two.

TRISOMY. An abnormal condition where three copies of one chromosome are present in the cells of an individual's body instead of two, the normal number.

TRITURATION. The process of diluting a nonsoluble substance for homeopathic use by grinding it to a fine powder and mixing it with lactose powder.

TROCAR. A small sharp instrument used to puncture the abdomen at the beginning of the laparoscopic procedure.

TROPHOBLAST. The tissues that surround an embryo and attach it to the uterus.

TROPHOZOITE. The active feeding stage of a protozoal parasite, as distinct from its encysted stage.

TRYPTOPHAN. An essential amino acid that has to consumed in the diet because it cannot be manufactured by the body. Tryptophan is converted by the body to niacin, one of the B vitamins.

TUBAL LIGATION. A surgical procedure in which the fallopian tubes are tied in two places and cut between. This prevents eggs from moving from the ovary to the uterus.

TUBAL PREGNANCY. Pregnancy in one of the fallopian tubes.

TUBE ENTEROSTOMY. An enterostomy performed to allow the insertion of a feeding tube into the jejunum or stomach.

TUBERCULIN. A mixture of antigens obtained from the cultured bacteria that cause tuberculosis, *Mycobacterium tuberculosis*.

TUBERCULOMA. A tumor-like mass in the brain that sometimes develops as a complication of tuberculosis meningitis.

TUBERCULOSIS. An infectious disease that usually affects the lungs, but may also affect other parts of the body. Symptoms include fever, weight loss, and coughing up blood.

TUBEROUS SCLEROSIS. A genetic disease that causes skin problems, seizures, and mental retardation. Autism occurs more often in individuals with tuberous sclerosis.

TUBULAR CARCINOMA. A type of cancer that accounts for approximately 1% to 2% of breast cancers. Can appear small on ultrasound or mammogram.

TUBULAR KIDNEY DISEASE. Disease of the kidney that affect the tubules, the part of the kidney that allows certain substances to be reabsorbed back into the blood.

TUBULE. A very small tube-shaped structure in the nephron of the kidney that removes certain ions and molecules from the blood and deposits them into the fluid within the tubule.

TUMOR. An abnormal growth resulting from a cell that lost its normal growth control restraints and started multiplying uncontrollably.

TUMOR LYSIS SYNDROME. A side effect of some immunotherapies, like monoclonal antibodies, that lyse the tumor cells, due to the toxicity of flooding the bloodstream with such a quantity of cellular contents.

TUMOR MARKERS. Biochemicals produced by tumor cells or by the body in response to tumor cells. Their levels in the blood help evaluate people for certain kinds of cancer.

TUMOR-SUPPRESSOR GENE. Gene involved in controlling normal cell growth and preventing cancer.

TUNICA ALBUGINEA. The sheath of elastic tissue enclosing the corpora cavernosa.

TUNICA VAGINALIS. A sac-like membrane covering the outer surface of the testis.

TURBIDIMETRY. A technique of measurement that analyzes the amount of sediment in a liquid.

TURBIDITY. The cloudiness or lack of transparency of a solution.

TURBINADO SUGAR. A type of sugar made from sugar cane extract. It resembles light brown sugar in color but is paler and has larger crystals. It is called demerara sugar in the United Kingdom.

TURBINATE. Ridge-shaped cartilage or soft bony tissue inside the nose.

TURNER'S SYNDROME. A disorder in women caused by an inherited chromosomal defect. This disorder inhibits sexual development and causes infertility. A symptom is absence of menstruation.

TWILIGHT ANESTHESIA. An intravenous mixture of sedatives and other medications that decreases patients' awareness of the procedure being performed.

TWIN REVERSED ARTERIAL PERFUSION (TRAP) SEQUENCE. A condition in which one fetus lacks a heart and the other fetus pumps the blood for both.

TWIN-TO-TWIN TRANSFUSION SYNDROME (TTTS). A condition in monochorionic twins in which there is a connection between the two circulatory systems so that the donor twin pumps the blood to the recipient twin without a return of blood to the donor.

TYMPANIC MEMBRANE. The eardrum. A thin disc of tissue that separates the outer ear from the middle ear.

TYMPANOSTOMY TUBE. Ear tube. A small tube made of metal or plastic that is inserted during myringotomy to ventilate the middle ear.

TYPE 1 DIABETES. A chronic immune system disorder in which the pancreas does not produce sufficient amounts of insulin, a hormone that enables cells to use glucose for energy. Also called juvenile diabetes, it must be treated with insulin injections.

TYPE 2 DIABETES. Sometimes called adult-onset diabetes, this disease prevents the body from properly using glucose (sugar), but can often be controlled with diet and exercise.

TYPHOID FEVER. An infectious disease caused by a type of bacterium. People with this disease have a lingering fever and feel depressed and exhausted. Diarrhea and rose-colored spots on the chest and abdomen are other symptoms. The disease is spread through poor sanitation.

TYPICAL USE. A measurement of the effectiveness of a contraceptive that counts all users, including those who use the method incorrectly or only occasionally.

TYROSINASE. An enzyme in a pigment cell which helps change tyrosine to DOPA during the process of making melanin.

TYROSINE. A protein building block found in a wide variety of foods that is used by the body to make melanin.

TZANCK PREPARATION. A procedure in which skin cells from a blister are stained and examined under the microscope.

U

UDANA. Life sustaining energy of the diaphragm, the third of the five airs of Ayurvedic philosophy, the life force governing upward motion.

ULCER. An open sore on the skin, resulting from tissue destruction, that is usually accompanied by redness, pain, or infection.

ULCERATED. Damaged so that the surface tissue is lost and/or necrotic (dead).

ULCERATION. A pitted area or break in the continuity of a surface, such as the skin or mucous membrane.

ULCERATIVE COLITIS. A disease of the colon characterized by inflammation of the mucous lining, ulcerated areas of tissue, and bloody diarrhea.

ULTRASONOGRAM. A procedure in which high-frequency sound waves that cannot be heard by human ears are bounced off internal organs and tissues. These sound waves produce a pattern of echoes that are then used by the computer to create sonograms or pictures of areas inside the body.

ULTRASONOGRAPHER. The person who performs the radiologic technique of ultrasound in which deep structures of the body are visualized.

ULTRASONOGRAPHY. Imaging test using sound waves to view internal organs and tissues.

ULTRASOUND. An imaging technique that uses sound waves to generate a picture of an internal structure in the body.

ULTRASOUND SCAN. The scan produces images of arteries on a screen and is used to evaluate the blood flow, locate blockages, and measure the size of the artery.

ULTRASOUND WAVES. High frequency sound waves.

ULTRAVIOLET (UV) LIGHT. A portion of the light spectrum not visible to the eye. It is damaging to living material, especially eyes and DNA.

ULTRAVIOLET RADIATION (UV). Invisible light rays that may be responsible for sunburns, skin cancers, and cataract formation.

UMBILICAL. Referring to the opening in the abdominal wall where the blood vessels from the placenta enter.

UMBILICAL CORD. The blood vessels that allow the developing baby to receive nutrition and oxygen from its mother; the blood vessels also eliminate the baby's waste products. One end of the umbilical cord is attached to the placenta and the other end is attached to the baby's belly button (umbilicus).

UMBILICAL CORD BLOOD TRANSPLANT. A procedure in which the blood from a newborn's umbilical cord, which is rich in stem cells, is used as the donor source for bone marrow transplants.

UMBILICUS. The area where the umbilical cord was attached; also known as the navel or belly button.

UNIFOCAL. Only one tumor present in one eye.

UNILATERAL. Located on or affecting only one side of the body.

UNIPARENTAL DISOMY. Chromosome abnormality in which both chromosomes in a pair are inherited from the same parent.

UNRESECTABLE CANCER. A tumor that cannot be completely removed by surgery.

UNSATURATED FAT. Fat found in plant foods that is typically liquid (oil) at room temperature. They can be monounsaturated or polyunsaturated, depending on the chemical structure. Unsaturated fats are the most recommended dietary fats.

UPPER ENDOSCOPY. A medical procedure in which a thin, lighted, flexible tube (endoscope) is inserted down the patient's throat. Through this tube the doctor can view the lining of the esophagus, stomach, and the upper part of the small intestine.

URATE CRYSTALS. Crystals formed by high levels of uric acid in the blood.

UREA. A compound containing nitrogen that occurs in the urine and other body fluids as a result of protein metabolism.

UREMIA. The presence of excessive amounts of urea and other waste products in the blood.

UREMIC POISONING. Accumulation of waste products in the body.

URETER. The tube-like passageway in the body that carries urine from the kidney to the bladder.

URETERAL STENT. A surgical device implanted in patients with damaged ureters that holds the ureter open so that urine can flow freely from the kidneys to the bladder.

URETEROVESICAL JUNCTION. The joining of the ureter to the bladder.

URETEROVESICAL VALVE. A sphincter (an opening controlled by a circular muscle), located where the ureter enters the bladder, that keeps urine from flowing backward toward the kidney.

URETHRA. The tube that carries urine from the bladder to outside the body. In females, the urethral opening is between the vagina and clitoris; in males, the urethra travels through the penis, opening at the tip.

URETHRA HYPERMOBILITY. Main factor in stress urinary incontinence, with severity based upon how far the urethra has descended into the pelvic floor through herniation or cystocele.

URETHRAL MEATUS. This is the external opening of the urethra.

URETHRAL STRICTURE. A narrowing of the urethra (urine tube).

URETHRITIS. Inflammation of the urethra.

URETOSCOPE. A tube-shaped device inserted into the body through the urinary system that allows objects to be both seen and grasped for removal.

URIC ACID. A compound resulting from the body's breakdown of purine. It is normally present in human urine only in small amounts.

URICOSURIA. Increased levels of uric acid in the urine.

URINALYSIS (PLURAL, URINALYSES). The diagnostic testing of a urine sample.

URINARY INCONTINENCE. The inability to control one's urine flow.

URINARY RETENTION. The result of progressive obstruction of the urethra by an enlarging prostate, causing urine to remain in the bladder even after urination.

URINARY TRACT. The passage through which urine flows from the kidneys out of the body.

URINE. The fluid containing water and waste products that is produced by the kidneys, stored in the bladder, and removed from the body through the urethra.

URINE DIPSTICK TEST. A test using a small, chemically treated strip that is dipped into a urine sample; when testing for protein, an area on the strip changes color depending on the amount of protein (if any) in the urine.

UROGENITAL. Both the urinary system and the sexual organs, which form together in the developing embryo.

UROGYNECOLOGIST. A physician that specializes in female medical conditions concerning the urinary and reproductive systems.

UROLOGIST. A physician who specializes in problems of the urinary system.

URORADIOLOGIST. A radiologist that specializes in diagnostic imaging of the urinary tract and kidneys.

UROSTOMY. A surgical opening (a stoma) created to divert urine to the outside of the body for collection once the bladder has been removed.

UROTHELIUM. The lining of the urinary tract, including the renal pelvis, ureters, bladder, and urethra.

UTERINE FIBROID. A noncancerous tumor of the uterus that can range from the size of a pea to the size of a grapefruit. Small fibroids require no treatment, but those causing serious symptoms may need to be removed.

UTERINE PROLAPSE. Bulging of the uterus into the vagina.

UTERUS. The hollow, muscular female organ that supports the development and nourishment of the unborn baby during pregnancy.

UVEA. The middle of the three coats of tissue surrounding the eye, comprising the choroid, iris, and ciliary body. The uvea is pigmented and well supplied with blood vessels.

UVEAL TRACT. The pigmented membrane that lines the back of the retina of the eye and extends forward to include the iris. The uveal tract is sometimes called the uvea and has three parts: the iris, the choroid, and the ciliary body.

UVEITIS. Inflammation of the area of the eye around the pupil.

UVULOPALATOPHARYNGOPLASTY (UPPP). An operation to remove excess tissue at the back of the throat to prevent it from closing off the airway during sleep.

V

VACCINATION. Injection of a killed or weakened microbe in order to stimulate the immune system against the microbe, thereby preventing disease. Vaccinations, or immunizations, work by stimulating the immune system, the natural disease-fighting system of the body. The healthy immune system is able to recognize invading bacteria and viruses and produce substances (antibodies) to destroy or disable them. Vaccinations prepare the immune system to ward off a disease. To immunize against viral diseases, the virus used in the vaccine has been weakened or killed.

VACCINE. A preparation using a non-infectious element or relative of a particular virus or bacteria, administered with the intention of halting the progress of an infection or completely preventing it.

VAGINA. The birth canal; the passage from the cervix of the uterus to the opening leading outside of a woman's body.

VAGINAL DISCHARGE. Discharge of secretions from the cervical glands of the vagina; normally clear or white.

VAGINAL PROLAPSE. Bulging of the top of the vagina into the lower vagina or outside the opening of the vagina.

VAGINAL STENOSIS. Narrowing of the vagina due to a buildup of scar tissue.

VAGINAL YEAST INFECTION. An overgrowth of fungus in the vaginal area.

VAGINISMUS. A painful spasmodic vaginal contraction.

VAGINITIS. Inflammation of the vagina.

VAGOTOMY. Cutting of the vagus nerve. If the vagus nerves are cut as they enter the stomach (truncal vagotomy), gastric secretions are decreased, as is intestinal motility (movement) and stomach emptying. In a selective vagotomy, only those branches of the vagus nerve are cut that stimulate the secretory cells.

VAGUS NERVE. Cranial nerves that supply the internal organs (viscera).

VALACYCLOVIR. An oral antiviral drug that blocks the replication of the varicella zoster virus.

VALSALVA MANEUVER. Pilots grunt and tighten their abdominal muscles to prevent black outs during high-performance flying.

VALVE. Tissue in the passageways between the heart's upper and lower chambers that controls passage of blood and prevents regurgitation.

VALVULAR. Having to do with the valves inside the heart.

VALVULAR HEART DISEASE. A disease of any one of the four valves that controls blood flow into, through, and out of the heart.

VAPORIZE. To dissolve solid material or convert it into smoke or gas.

VARIABLE DECELERATION. Fetal bradycardia below 100 beats per minute denoting compression of the umbilical cord at the height of a uterine contraction.

VARICELLA. Chickenpox; a disease caused by the *Varicella zoster* virus—human herpes virus 3—that can cause severe birth defects if transmitted to the fetus during the first 20 weeks of pregnancy and newborn complications if it is transmitted perinatally.

VARICELLA–ZOSTER IMMUNE GLOBULIN (VZIG). A substance that can reduce the severity of chickenpox symptoms.

VARICES. Swollen or enlarged veins.

VARICOCELE. An abnormal enlargement of the veins which drain the testicles.

VARICOSE VEINS . Twisted, enlarged veins near the surface of the skin, which develop most commonly in the legs and ankles.

VARIEGATION. Patchy variation in color.

VAS DEFERENS. The duct that stores sperm and carries it from the epididymis to the ejaculatory duct.

VASCULAR. Pertaining to blood vessels.

VASCULITIS. An inflammation of the blood vessels.

VASCULOGENIC ERECTILE DYSFUNCTION. The inability to attain or sustain an erection satisfactory for coitus, due to atherosclerotic disease of penile arteries, inadequate impedance of venous outflow (venous leaks), or a combination of both.

VASECTOMY. Surgical sterilization of the male, done by removing a portion of the tube that carries sperm to the urethra.

VASOCONSTRICTION. Constriction of a blood vessel.

VASODILATATION. The increase in the internal diameter of a blood vessel that results from relaxation of smooth muscle within the wall of the vessel thus causing an increase in blood flow.

VASODILATOR. A class of drugs that widen the blood vessels, that in turn decreases resistance to blood flow and lowers blood pressure.

VASOPRESSORS. Medications that constrict the blood vessels.

VASOSPASM. Narrowing of a blood vessel caused by a spasm of the smooth muscle of the vessel wall.

VASOVAGAL REACTION. Regarding the action of stimuli from the vagus nerve on blood vessels.

VATA. One of the three main constitutional types found under Ayurvedic principles. Keeping one's particular constitution in balance is considered important in maintaining health.

VBAC. Vaginal birth after cesarean.

VECTOR. An animal carrier that transfers an infectious organism from one host to another.

VEGETATION. An abnormal growth of tissue around a valve, composed of blood platelets, bacteria, and a protein involved in clotting.

VEIN. A blood vessel that returns oxygen-depleted blood from various parts of the body to the heart.

VENA CAVA. The large vein that drains directly into the heart after gathering incoming blood from the entire body.

VENEREAL DISEASE. Another term for sexually transmitted disease.

VENESECTION. Another name for phlebotomy.

VENOARTERIAL (V-A) BYPASS. The type of ECMO that provides both heart and lung support, using two tubes (one in the jugular vein and one in the carotid artery).

VENOM. A poisonous substance secreted by an animal, usually delivered through a bite or a sting.

VENOUS STASIS DISEASE. A condition in which there is pooling of blood in the lower leg veins that may cause swelling and tissue damage, and lead to painful sores or ulcers.

VENOVENOUS (V-V) BYPASS. The type of ECMO that provides lung support only, using a tube inserted into the jugular vein.

VENTILATOR. A mechanical device that can take over the work of breathing for a patient whose lungs are injured.

VENTRICLES. The two chambers of the heart that are involved in pumping blood. The right ventricle pumps blood into the lungs to receive oxygen. The left ventricle pumps blood into the circulation of the body to deliver oxygen to all of the body's organs and tissues.

VENTRICULAR FIBRILLATION. A condition in which the lower chamber of the heart quivers instead of pumping in an organized way.

VENTRICULAR SEPTAL DEFECT (VSD). A defect or opening in the ventricular septum, the wall of tissue that separates the two lower chambers of the heart.

VENTRICULAR TACHYCARDIA. A rapid heartbeat, usually more than 100 beats per minute.

VERMILION BORDER. The line between the lip and the skin.

VERTEBRA (PLURAL, VERTEBRAE). One of the bones of the spinal column. There are 33 vertebrae in the human spine.

VERTEBRAL COLUMN. The vertebral column, also called the spinal column or spine, consists of a series of vertebrae connected by ligaments. It provides a supporting axis for the body and protects the spinal cord. The vertebral column consists of seven cervical vertebrae in the neck, followed by 12 thoracic vertebrae that

connect to the ribs, five lumbar vertebrae in the lower back, the sacrum, and the coccyx.

VERTEBROBASILAR ARTERIES. Major blood vessels that lead to the brain. They are located at the base of the skull at the back of the head.

VERTIGO. The sensation of moving around in space, or objects moving around a person. It is a disturbance of equilibrium.

VESICLE. A bump on the skin filled with fluid.

VESTIBULAR SYSTEM. The brain and parts of the inner ear that work together to detect movement and position.

VESTIBULECTOMY. Surgical removal of the vestibule and hymen.

VESTIBULOCOCHLEAR NERVE (EIGHTH CRANIAL NERVE). Nerve that transmits information, about hearing and balance from the ear to the brain.

VIAGRA. Trade name of an orally administered drug for erectile failure first cleared for marketing in the United States in March 1998. Its generic name is sildenafil citrate.

VIBRATION. A procedure to help break up lung secretions, performed as the patient breathes deeply. When done manually, the person performing the vibration places his or her hands against the patient's chest and creates vibrations by quickly contracting and relaxing arm and shoulder muscles while the patient exhales. The procedure is repeated several times each day for about five exhalations.

VIBROACOUSTIC STIMULATION. In the biophysical profile, use of an artificial larynx to produce a loud noise to "awaken" the fetus.

VIDEO-ASSISTED THORACIC SURGERY (VATS). A technique used to aid in the placement of chest tubes or when performing decortications when treating advanced empyema.

VIDEOSCOPE. A surgical camera.

VILLI. Tiny, finger–like projections that enable the small intestine to absorb nutrients from food.

VIRAL LOAD. A measure of the severity of a viral infection, calculated by estimating the number of copies of the virus in a milliliter of blood.

VIRAL LOAD TEST. A new blood test for monitoring the speed of HIV replication in AIDS patients. The viral load test is based on PCR techniques and supplements the CD4+ cell count tests.

VIRTUAL COLONOSCOPY. Two new techniques that provide views of the colon to screen for colon polyps and cancer. The images are produced by computerized manipulations rather than direct observation through the colonoscope; one technique uses the X-ray images from a CT scan, and the other uses magnetic images from an MRI scan.

VIRUS. A tiny, disease-causing structure that can reproduce only in living cells and causes a variety of infectious diseases.

VISCERA. Any of the body's organs located in the chest or abdomen.

VISCERAL LARVA MIGRANS (VLM). Another name for toxocariasis. The name is derived from the life cycle of the organism.

VISUAL ACUITY. Sharpness or clearness of vision.

VISUAL ACUITY TEST. An eye examination that determines sharpness of vision, typically performed by identifying objects and/or letters on an eye chart.

VISUALIZATION. The process of making an internal organ visible. A radiopaque subtance is introduced into the body, then an x-ray picture of the desired organ is taken.

VISUAL-MOTOR SKILLS. Hand-eye coordination; in the Bender-Gestalt test, visual-motor skills are measured by the subject's ability to accurately perceive and then reproduce figures.

VISUAL-PERCEPTUAL SKILLS. The capacity of the mind and the eye to "see" something as it objectively exists.

VITAL CAPACITY (VC). The largest amount of air expelled after one's deepest inhalation.

VITAL SIGNS. Basic indicators of body function, usually meaning heartbeats per minute, breaths per minute, blood pressure, body temperature, and weight.

VITAMIN. An essential nutrient the body needs in small amounts to remain healthy but that the body cannot manufacture for itself and must acquire through diet.

VITAMIN D. Any of several fat-soluble vitamins that are required for normal bone and teeth structure and various other physiological functions. Vitamin D is obtained from some foods and is produced in the body through the action of ultraviolet radiation.

VITAMIN STATUS. Vitamin status refers to the state of vitamin sufficiency or deficiency of any person. For example, a test may reveal that a patient's folate status is sufficient, borderline, or severely inadequate.

VITILIGO. A chronic skin disorder that causes loss of pigmentation (color) from patches of skin, most often on the face, hands, and wrists.

VITREOUS. The transparent gel that fills the back part of the eyeball, behind the lens; also referred to as the vitreous body.

VITREOUS HUMOR. The clear gel-like substance that fills the eyeball behind the lens.

VITREOUS SEEDING. When small pieces of tumor have broken off and are floating around the vitreous.

VOICE BOX. The larynx.

VOIDING. Another word for emptying the bladder or urinating.

VOLATILE. Something that vaporizes or evaporates quickly when exposed to air.

VOLATILE ORGANIC COMPOUNDS. VOCs, a large class of carbon-based chemicals that release gases into the air as they evaporate at room temperature. Found both in natural sources such as living trees, decomposing vegetation, and crude oil, and in manmade sources such as solvents, adhesives, and gasoline, VOCs help form ozone at ground levels and are major air contaminants.

VOLATILE SOLVENTS. Liquids that vaporize at room temperature, including a variety of industrial and household products and art and office-supply solvents.

VOLTAGE. The force necessary to drive an electric current between two specified points. A large voltage exerts a greater force, which moves more electrons through a wire at a given rate of time.

VOLUNTARY. An action or thought undertaken or controlled by a person's free will or choice.

VOLUNTARY MUSCLE. A muscle under conscious control, such as arm and leg muscles.

VOLVULUS. A twisting of the intestine that causes an obstruction.

VON WILLEBRAND FACTOR (VWF). A protein found in the blood that is involved in the process of blood clotting.

VON WILLEBRAND'S DISEASE. An inherited lifelong bleeding disorder caused by an abnormal gene, similar to hemophilia. The gene defect results in a decreased blood concentration of a substance called von Willebrand's factor (vWF).

VOYEURISM. Sexual stimulation by visual means, usually by observing an unsuspecting individual.

VULVA. The external female genitalia including the mons pubis, labia majora and minora, clitoris, vestibule, glands, and the vaginal opening.

VULVAR VESTIBULITIS. A localized inflammation of the vestibule—the region immediately surrounding the opening of the vagina and the urethra.

VULVODYNIA. A chronic burning, stinging, or irritation of the vulva.

VYANA. Life sustaining energy of the heart and lungs; the second of the five airs of Ayurvedic philosophy; the life force governing circular motion.

W

WARFARIN. A drug that reduces the ability of the blood to clot.

WART. A raised growth on the surface of the skin or other organ.

WARTHIN'S TUMOR. A benign tumor of the parotid gland.

WASTING SYNDROME. A combination of weight loss and change in composition of body tissues that occurs in patients with HIV infection. Typically, the patient's body loses lean muscle tissue and replaces it with fat as well as losing weight overall.

WATER BRASH. The flow of saliva and stomach acid back up the esophagus and into the throat or lungs.

WATER HOMEOSTASIS. A condition of adequate fluid level in the body in which fluid loss and fluid intake are equally matched and sodium levels are within normal range.

WATER INTOXICATION. A potentially life-threatening condition caused by drinking too much water, which leads to hyponatremia and may result in seizures, coma, and death.

WATER-SOLUBLE VITAMINS. Vitamins that are not stored in the body and are easily excreted. They must, therefore, be consumed regularly as foods or supplements to maintain health.

WBC DIFFERENTIAL. A white blood cell count in which the technician classifies the different white blood cells by type as well as calculating the number of each type. A WBC differential is necessary to calculate the absolute CD4+ lymphocyte count.

WEBER TEST. A hearing test using a vibrating tuning fork which is held at various points along the midline of the skull and face.

WEGENER'S GRANULOMATOSIS. A disease usually affecting males that causes the infiltration of inflammatory cells and tissue death in the lungs, kidneys, blood vessels, heart, and other tissues.

WERNICKE-KORSAKOFF SYNDROME. A combination of symptoms, including eye-movement problems, tremors, and confusion, that is caused by a lack of the B vitamin thiamine and may be seen in alcoholics.

WERNICKE'S APHASIA. A condition characterized by either partial or total loss of the ability to understand what is being said or read. The individual maintains the ability to speak, but speech may contain unnecessary or made-up words.

WESTERN BLOT. A procedure that uses electrical current passed through a gel containing a sample of tissue extract in order to break down the proteins in the sample and detect the presence of antibodies for a specific disease. The Western blot method is used in HIV testing to confirm the results of an initial screening test.

WHEEZE. A whistling sound made by the flow of high-velocity air through narrowed airways. Wheezing is a symptom of several respiratory diseases including byssinosis and asthma.

WHIPPLE PROCEDURE. Surgical removal of the head of the pancreas, part of the small intestine, and some surrounding tissue.

WHIPPLE'S DISEASE. A disorder of impaired absorption of nutrients by the small intestine. Symptoms include diarrhea, abdominal pain, progressive weight loss, joint pain, swollen lymph nodes, abnormal skin pigmentation, anemia, and fever. The precise cause is unknown, but it is probably due to an unidentified bacterial infection.

WHIPWORM. A nematode worm of the family Trichuridae with a body that is thick at one end and very long and slender at the other end.

WHITE BLOOD CELL (LEUKOCYTE; WBC). A blood cell that is responsible for fighting infection.

WHOLE BLOOD. Blood that contains red blood cells, white blood cells, and platelets in plasma.

WHOOPING COUGH. An infectious disease, also called pertussis, especially of children that is caused by a bacterium and is marked by a convulsive, spasmodic cough, sometimes followed by a shrill intake of breath.

WILDCRAFTING. Gathering of herbs or other natural materials.

WILDERNESS. Large backcountry areas lacking roads, communication and other modern infrastructure.

WILSON'S DISEASE. A genetic disorder in which copper accumulates in the body, leading to liver disease and a variety of neurological and psychiatric symptoms.

WINDOW OPERATION. Cutting out a large oval-shaped piece of the cyst wall and putting in stitches to create a window so the cyst cannot reoccur.

WINDOW PERIOD. The period of time between a person's getting infected with HIV and the point at which antibodies against the virus can be detected in a blood sample.

WIRELESS CAPSULE ENDOSCOPY. A newer method of examining the small bowel by means of a capsule swallowed by the patient. The capsule contains a miniaturized lens and an antenna that transmits information to a belt-pack recorder worn by the patient during the day.

WISDOM TOOTH. One of the four last teeth on the top and bottom rows of teeth. Also called a third molar.

WITHDRAWAL. Physical symptoms and psychological discomforts experienced after a person suddenly stops using a drug on which he or she has become dependent.

"WHEAL AND FLARE" REACTION. A rapid response to a skin allergy test characterized by the development of a red, itching spot in the area where the allergen was injected.

WOLFF-PARKINSON-WHITE SYNDROME. An abnormal, rapid heart rhythm, due to an extra pathway for the electrical impulses to travel from the atria to the ventricles.

WOOD'S LAMP. A special lamp that uses ultraviolet light to detect certain types of skin infections and infestations. It was invented in 1903 by a physicist named Robert Wood.

WORD CATHETER. A small rubber catheter with an inflatable balloon tip that is inserted into a stab incision in the cyst, after the contents of the cyst have been drained.

WORD SALAD. Speech that is so disorganized that it makes no linguistic or grammatical sense.

WORKING MEMORY. The memory system that relates to the task at hand and coordinates recall of memories necessary to complete it.

WOUND. Any injury that breaks the skin, including cuts, scratches, and puncture wounds.

WRIGHT'S STAIN. A chemical used to stain tissue samples for laboratory analysis.

X

X CHROMOSOME. One of the two types of sex chromosomes; females have two X chromosomes, while males have one X chromosome and one Y chromosome.

X RAY. A form of electromagnetic radiation with shorter wavelengths than normal light. X rays can penetrate most structures.

XANTHOMAS. Fatty yellow patches or nodules on the skin or internal tissues.

XENOGRAFT. Tissue that is transplanted from one species to another (e.g., pigs to humans).

XENOTRANSPLANT. Transplantation of animal cells or tissues into a human.

XERODERMA PIGMENTOSUM. A genetic disease characterized by the inability to repair damaged DNA. Individuals with this disease develop an excessive number of skin cancers.

XEROPHTHALMIA. A drying of the cornea and conjunctiva.

XEROSTOMIA. The medical term for dry mouth.

X-LINKED. Refers to a gene carried on the X chromosome, one of the two sex chromosomes.

X-LINKED DOMINANT INHERITANCE. The inheritance of a trait by the presence of a single gene on the X chromosome in a male or female, passed from an affected female who has the gene on one of her X chromosomes.

X-LINKED GENE. A gene carried on the X chromosome, one of the two sex chromosomes.

X-LINKED HYPOPHOSPHATEMIA,. A type of rickets caused by genetic factors which prevent the kidneys from retaining phosphate.

X-LINKED RECESSIVE INHERITANCE. The inheritance of a trait by the presence of a single gene on the X chromosome in a male, passed from a female who has the gene on one of her X chromosomes, and who is referred to as an unaffected carrier.

Y

YELLOW FEVER. An infectious disease caused by a virus. The disease, which is spread by mosquitoes, is most common in Central and South America and Central Africa. Symptoms include high fever, jaundice (yellow eyes and skin) and dark-colored vomit, a sign of internal bleeding. Yellow fever can be fatal.

YIN/YANG. Complimentary universal characteristics used to describe aspects of the natural world.

YOGA. A system of exercise aimed at promoting the control of the body and the mind.

YOGI (FEMALE, YOGINI). A trained practitioner of yoga.

YOLK SAC. A sac made of membranous tissue which is attached to the embryo and which provides nutrition to the embryo.

YUZPE REGIMEN. A form of emergency contraception in which two oral contraceptive pills that contain both of the hormones estrogen and progestin are taken to prevent pregnancy.

Z

ZAFIRLUKAST (ACCOLATE). An inhibitor that prevents leukotrienes from binding to cell receptors; taken over time, zafirlukast can help reduce or prevent asthma symptoms.

ZELLWEGER SPECTRUM. Three peroxisome biogenesis disorders—Zellwinger syndrome, neonatal adrenoleukodystrophy, and infantile Refsum disease—which can be caused by different mutations in the same genes and which differ only in the severity of the resulting condition.

ZEN. A form of meditation that emphasizes direct experience.

ZIFT. Stands for zygote intrafallopian tube transfer. In in vitro fertilization, the eggs are fertilized in a laboratory dish and then placed in the woman's fallopian tube.

ZILEUTON (ZYFLO). A medication that interferes with the biosynthetic pathway that produces leukotrienes; used to help prevent asthma attacks.

ZOLLINGER-ELLIZON SYNDROME. Severe peptic ulceration from excessive stomach acid production stimulated by one or more tumors that produce a powerful acid secretion.

ZONE THERAPY. Also called zone analgesia, a method of relieving pain by applying pressure to specific points on the body. It was developed in the early twentieth century by Dr. William Fitzgerald.

ZOONOSIS (PLURAL, ZOONOSES). Any disease of animals that can be transmitted to humans under natural conditions. Lyme disease, rabies, psittacosis (parrot fever), cat-scratch fever, and monkeypox are examples of zoonoses.

ZOONOTIC DISEASES. Diseases caused by infectious agents that can be transmitted between (or are shared by) animals and humans. This can include transmission through the bite of an insect, such as a mosquito.

ZYGOMYCOSIS. Another term for mucormycosis. The fungi that cause mucormycosis belong to a group called Zygomycetes.

ZYGOTE. A fertilized egg.

INDEX

In the index, references to individual volumes are listed before colons; numbers following a colon refer to specific page numbers within that particular volume. **Boldface** references indicate main topical essays. Photographs and illustration references are highlighted with an *italicized* page number, and tables are also indicated with the page number followed by a lowercase, italicized *t*.
